Chrysocolla is a secondary mineral and associated commonly with other copper minerals of similar origin. Among the localities for excellent specimens may be mentioned Cornwall and Cumberland, England; Belgian Congo; Chile; Lebanon and Berks Counties, Pennsylvania; the Clifton-Morenci Globe and Bisbee districts in Arizona; Dona Ana County, New Mexico, and the Tintic district, Utah.

The word chrysocolla is derived from the Greek words meaning gold and glue, formerly the name for gold solder. Chrysocolla is one of the less important ores of copper and has a minor use as a gem stone. (E.S.C.S.)

CHRYSOLITE. Olivine.

CHRYSOMONADIDA. One-celled animals of yellow or brown color, or colorless, constituting an order of **Mastigophora.** (A.W.L.)

CHRYSOPRASE. Chalcedony.

CHRYSOTILE. A delicately fibrous variety of **serpentine** which separates easily into silky flexible fibers of greenish or yellowish color. Its name is derived from the Greek words meaning gold and fibrous. Most of the common asbestos of commerce is chrysotile. It is mined in Thetford, Province of Quebec, and in South Africa. (E.S.C.S.)

CHUB. Pisces, Teleostei. A European fish (**Pisces**), *Leuciscus cephalus,* related to the dace, and several North American species. One, an excellent food and game fish, is the fallfish, *Leucosomus corporalis,* or chub of northeastern streams and lakes. Another, the horned dace, *Semotilus atromaculatus,* creek chub, or common chub, is widely distributed in the United States and Canada with the exception of the far west. In small streams it becomes abundant and sometimes rises to the fly as freely as the game fishes. Its flesh is usually lacking in flavor. Other species of the group are sometimes called chubs. (A.W.L.)

CHUB SUCKER. Pisces, Teleostei. A small **sucker,** *Erimyzon sucetta,* of rather stout build, common throughout the eastern half of the United States. (A.W.L.)

CHUCK. A rotating vise which may be attached to the spindle of a machine. There are two important varieties of lathe chucks, independent and universal. In general, the *independent chuck* has four jaws each of which is separately actuated and adjusted. It may be employed for almost any type of work, cylindrical, square, or irregular. In turning cylindrical work, it is necessary to adjust the jaws very carefully, and test the concentricity of the work and spindle axes with some form of indicator. When a 4-jaw independent chuck is employed for repetitive work, only two adjacent jaws are actuated as each new part is placed in the chuck after the initial adjustment and alignment of the jaws have been obtained.

Three-jaw *universal* or self-centering chucks are employed for cylindrical and hexagonal bar stock. The jaws are simultaneously advanced or retracted by turning the scroll plate in which the jaw teeth fit. On account of the curvature of the scroll, it is necessary to

have separate sets of jaws for inside and outside clamping, in contrast to the independent chuck where the jaws may be reversed. Combination chucks combine an independent chuck for holding odd-shaped work; a universal chuck for self-centering and gripping round or square work; 2-jaw universal chucks have jaws to which special adapters may be fitted and are employed principally in turret lathe work.

Independent and universal chucks may be attached to a threaded adapter which screws on the spindle nose. These chucks may also be obtained with adapters to fit heavy-duty taper spindle noses; the chuck is drawn on the spindle nose by the engagement of the "pull-on" nut with the externally-threaded hub of its adapter.

Air-operated chucks have a body with two jaws and work-holding adapters with an actuating wedge which closes and opens the jaws by moving parallel to the chuck axis. The actuating wedge is threaded so that a draw-rod may be attached. The other end of the draw-rod is attached to a piston operating in an air cylinder which is attached to the lathe headstock. The piston is double-acting so that the chuck jaws may be both opened and closed by the action of compressed air. The chuck is operated by a valve convenient to the machine operator. Air- and oil-operated chucks are generally employed for production work, as in turret and chucking lathes.

Draw-in chucks and collets are used for bar work, and are designed to fit on the heavy-duty spindle nose if the live center is removed. The collets, which are of various sizes, fit in the chuck and are clamped with a removable key or wrench. Drawing in the spring collet forces its outer surface against the taper on the inside of the chuck; releasing the collet causes its jaws to open by their spring action. Bars of any length may be held in the chuck, extending entirely through the hole in the spindle if necessary. Collets for all standard sizes of circular rod are available as well as collets for hexagonal bar stock and cylindrical metric sizes. Magnetic chucks of both the electrically-actuated and the permanent-magnet type may also be employed on the lathe. (H.C.H.)

Three-jaw universal chucks are used on drill presses. Rotating the outer sleeve by hand or by a key fitted to the sleeve gear teeth, opens and closes the three self-centering jaws. The arbor hole in the drill chuck fits the tapered end of the drill press spindle. *Bayonet chucks* are single-purpose chucks and are used on automatic drilling machinery. They are equipped with a bayonet slot for rapid attachment and release.

CHUCK-WALLA. Reptilia, Sauria. A common **lizard,** *Sauromalus obesus,* of the southwestern deserts, ranging into Utah and Nevada. It attains a length of 11″ and is sometimes eaten. (A.W.L.)

CHUCK-WILL'S-WIDOW. Goatsucker.

CICADA. Insecta. Homoptera. Large **insects** of many species. They are stoutly built and have two pairs of membranous wings which are folded roof-like over the body when at rest. They are best known for the loud songs of the males, which are produced by a pair of elaborate organs located on the under surface at the base of the abdomen. These organs have a vibrating structure controlled by special muscles and thin resonating parts which result in a peculiarly penetrating sound.

The female has a powerful **ovipositor** with which she punctures the twigs of trees and shrubs to deposit her eggs. The young cicada does not remain in the twig but drops to the ground and burrows, feeding on the roots of plants. In the case of one species, *Tibicina septendecim,* the duration of the larval period is unusually long and has resulted in the name seventeen-year locust. Locust is inaccurately but very commonly applied to these insects and some are called harvest-flies.

Great damage is sometimes done to young orchard trees by the breaking of twigs where the eggs have been deposited, especially after one of the great broods of the seventeen-year locust, or periodical cicada, has passed. The only effective protection is to cover young trees with inexpensive cloth when such a brood is imminent; the years of emergence are known by economic entomologists and can readily be learned for any part of the country. (A.W.L.)

CICHLID. Pisces, Teleostei. Fishes (**Pisces**) of a large family, including several hundred species, found in tropical and subtropical waters of India, Africa, and the New World. They occur in both fresh and brackish water.

A number of species of cichlids are offered by dealers in tropical fishes for aquaria. They include beautifully colored fishes and are interesting for their breeding habits; the eggs are carried in the mouth or **pharynx** until they hatch. (A.W.L.)

CICONIIFORMES. An order of long-legged wading birds (**Aves**) including the **herons, flamingoes, bitterns, storks** and others. (A.W.L.)

CIDAROIDA. An order of sea-urchins without gills around the mouth. (A.W.L.)

CIENEGA. A type of spring which occurs in intermontane basin deposits or **bolsons,** especially of semi-arid to arid regions. When the underground waterbearing stratum, or **aquifer,** is blocked by cemented gravels the water may be forced by hydrostatic pressure to the surface, forming the type of spring called a cienega. (R.M.F.)

CILIARY JUNCTION. An association of separate **gill filaments** in certain **bivalve** mollusks, which is characterized by interlocking **cilia.** (A.W.L.)

CILIATA. One-celled animals which have **cilia** during adult life but are without suctorial tentacles. They constitute a class of this name in the subphylum **Ciliophora.** (A.W.L.)

CILIOPHORA. A subphylum of the phylum **Protozoa** containing species which have cilia or cirri during some stage of life. They vary greatly in form and habits. Some are sessile, some free swimming, and some parasitic.

The following is a brief summary of a classification of ciliates now widely used:

- Class Ciliata. With cilia or cirri throughout life.
  - Subclass Protociliata. Leaf-like species with two to many nuclei. Parasitic in the intestines of fishes and amphibians. *Opalina* and related forms.
  - Subclass Ciliata (Euciliata). With two kinds of nuclei, large and small (macronucleus and micronucleus).
    - Order Holotrichida. **Cilia** uniformly distributed. *Paramecium* and many other genera.
    - Order Heterotrichida. With a zone of cilia of larger size, or membranelles, associated with the mouth. *Stentor.*
    - Order Oligotrichida. With cilia about the mouth but few on the body.
    - Order Hypotrichida. Flattened, with cilia or cirri on the under surface. *Stylonychia,* etc.
    - Order Peritrichida. Oral end of body enlarged, ciliated, many species stalked. *Vorticella,* etc.
- Class Suctoria. With cilia only during early life. Adults sessile, with tentacles for ingesting food and for piercing. (A.W.L.)

CILIUM. A slender hair-like process of minute size on the surface of a cell. It is part of the living **cytoplasm.** In association with their minute size cilia occur in relatively large numbers and act in unison to produce aggregate effects. They are capable of waving movement. Commonly they bend consecutively in the same direction so that a wave of movement passes along the ciliated surface, followed by the return of the cilia to the resting position and this again by their bending. This type of movement is said to be metachronal. The successive waves follow each other closely so that several may be apparent at the same time.

Cilia are found in many species of Protozoa and give the name Ciliophora to one subdivision of the phylum. Among the multicellular animals they occur on the surface of the body in a few groups (e.g., **coelenterates, turbellarian** worms and **molluskans**) during adult life and in many larvae such as those of the **echinoderms,** the **annelid** worms, coelenterates, and others. They are also found on epithelia of limited distribution in many complex animals, as in the mantle cavity of mollusks and the trachea of man.

Cilia on the surface of small animals, such as the **Protozoa** and **larvae** of greater complexity, are able by their action against a surrounding liquid to propel the animal and so serve as organs of locomotion. In animals of larger size, in those which are not surrounded by a liquid medium, on sessile forms, and where the direction of their movement is contrary to the movements of propulsion, they act to set up currents either in liquids secreted by the body or in the surrounding medium. Thus some cilia in Protozoa, coelenterates, and mollusks direct a current bearing food and oxygen into the gullet and in man cilia carry toward the throat the mucus secreted by glands in the lining of the trachea. This secretion may bear foreign particles which have been inhaled. (A.W.L.)

CINCHONA. *Cinchona Calisaya* and other species. Rubiaceae. This is a small tree (30–40′ high) with light green leaves and pink flowers. It is native in Bolivia. There, because of the destructive habit of chopping the trees down in order to obtain the bark, the wild tree has almost disappeared. In 1859 the plant was introduced into the East Indies, where it was so widely cultivated as to produce a tremendous decrease in the price of the bark.

The bark is the source of the drug quinine, a bitter alkaloid used as a preventive and cure for **malaria.** When the trees are seven or more years old, they are felled, and the bark removed Other methods of collection include uprooting the tree to secure the root bark in addition to the stem bark and scraping the outer bark from living trees. The yield of quinine is increased by protecting the stem of the tree from sunlight, as by covering trunk and branches with moss. Coppicing is also practiced (see **Cinnamon**). Production for world trade at present is centered largely in the Dutch East Indies, particularly in Java. (R.M.W., B.S.M.)

CINCHONIDINE. Alkaloids.

CINGULUM. 1. A girdle, such as the outer ciliated ring at the anterior end of a **rotifer.** 2. A bundle of association fibers in the mammalian **brain,** partially encircling the corpus callosum not far from the median plane. 3. The basal ridge of a tooth. (A.W.L.)

CINNABAR. The mineral cinnabar, mercuric sulfide (HgS) occurs in small and often highly modified hexagonal crystals, usually of rhombohedral or tabular habit. It is found chiefly in crystalline crusts, granular or simply massive. The fracture of cinnabar is subconchoidal; hardness, 2–2.5; specific gravity, 8–8.2; luster, adamantine tending toward metallic, sometimes dull. This mineral has a characteristic cochineal-red color which, however, may be brownish at times, occasionally dull lead gray. The streak is scarlet; it is transparent to opaque.

Cinnabar occurs in veins or may be in masses in **shales, slates, limestones** and similar rocks due to the impregnation by mineral-bearing solutions or as replacements. Russia, Czechoslovakia, Bohemia, Bavaria, Italy and Spain have furnished excellent specimens. The most important of the world's mercury deposits is at Almadin in Spain. Italy, Peru, Dutch Guiana, China and Mexico have commercially valuable occurrences of cinnabar. In the United States this mineral is found in California (most important deposit), Nevada, Utah, Texas and Oregon. Cinnabar is the chief ore of mercury. Its name is supposed to be of Hindu origin. (E.S.C.S.)

CINNAMON. **Cinnamomum zeylanicum.** Lauraceae. Cinnamon is obtained from a small tree native to Ceylon and India, where the plant is now extensively grown in cultivation. The trees grow from 25–40′ high, have shining dark green leathery leaves, small whitish flowers having a rather disagreeable odor, and dark purple fruits. The bark of young twigs is smooth and somewhat mottled; in older branches and the main stem, the bark becomes thick, rough and of little value. To insure the desideratum of many young branches, the limbs are severed so that many slender branches will form, a practice known as coppicing. From these slender stems the bark is removed by lengthwise splitting and partial loosening from the stem; as it dries it rolls back. It is then removed from the stem, the dry useless **periderm** scraped off, and the inner bark remaining allowed to dry completely. During drying its color changes from pale yellow to deep brown The tight rolls of dried bark are packed together in bundles, called pipes, and are ready for marketing.

This bark contains considerable amounts of a powerful drug which in large doses is a dangerous poison. The principal use of cinnamon is as a spice for pastries. By distillation of cinnamon stems and leaves there is obtained oil of cinnamon (see **Volatile Oils**), used in flavoring candy and in scenting soap. (R.M.W., B.S.M.)

CIPOLIN. A **metamorphic** rock transitional between a **marble** and **mica-schist** in which the principal **mica** is **phlogopite.** (R.M.F.)

CIRCLE. A circle is a plane curve such that all of its points are at a fixed distance, called the radius, from a fixed point called its center.

The length of the circumference of a circle of radius r is given by $C = 2\pi r$, its area by $A = \pi r^2$.

The area of a circular sector is given by $A = \frac{1}{2}r^2\theta$, where r is the radius of the circle and θ is the **radian measure** of the angle of the sector.

The area of a segment of a circle (between a circle and a chord) is given by $A = \frac{1}{2}r^2(\theta - \sin\theta)$, where r is the radius of the circle and θ is the radian measure of the angle of the segment.

In **rectangular coordinates,** the equation of the circle of radius r with center at the origin is

$$x^2 + y^2 = r^2;$$

and the equation of the circle of radius r with center at the point (h, k) is

$$(x - h)^2 + (y - k)^2 = r^2.$$

Any equation, in rectangular coordinates, of the form $Ax^2 + Ay^2 + Bx + Cy + D = 0$ represents a circle. For the circle whose equation is $x^2 + y^2 + Dx + Ey + F = 0$, the center is $(-\frac{1}{2}D, -\frac{1}{2}E)$ and the radius is $\frac{1}{2}\sqrt{D^2 + E^2 - 4F}$ if this latter expression is real. A circle is determined by three conditions.

In **polar coordinates,** if the center is on the polar axis and the circle passes through the pole, its equation is $r = 2a\cos\theta$ (if the center is to the right of the pole) or

$r = -2a \cos\theta$ (if the center is to the left of the pole), where a is the radius of the circle. If the center is on a line perpendicular to the polar axis through the pole and the circle passes through the pole, the equation of the circle is $r = \pm 2a \sin\theta$, where the $+$ or $-$ sign is to be used according as the center is above or below the pole. If the center is at the pole, the equation of the circle is $r = a$. If the circle passes through the pole and has X- and Y-intercepts a and b, its polar equation is $r = a\cos\theta + b\sin\theta$.

The simplest **parametric equations** of a circle are: $x = a\cos\theta$, $y = a\sin\theta$, where a is the radius and θ is the angle XOP, and P is the point (x, y).

If $C_1 = 0$ and $C_2 = 0$ are the equations of two given circles, then $C_1 + kC_2 = 0$ is the equation of the system of all circles passing through the intersections of the given circles, if k takes all positive and negative values.

If $x^2 + y^2 + D_1x + E_1y + F_1 = 0$ and $x^2 + y^2 + D_2x + E_2y + F_2 = 0$ are the equations, in rectangular coordinates, of two given circles, then the straight line whose equation is $(D_1 - D_2)x + (E_1 - E_2)y + (F_1 - F_2) = 0$ is called the radical axis of the given circles. It is perpendicular to the line of centers of the given circles. If the given circles intersect (or touch) each other, the radical axis is their common chord (or common tangent). The radical axis of two circles is the locus of all points from which the lengths of the tangents to the circles are equal.

If three circles are given, and the three radical axes of these circles taken in pairs are found, it will be found that they intersect in a common point, which is called the radical center of the three given circles.

The length along the tangent from a point (x_1, y_1) to a circle of radius r and center (h, k) is given by

$$t^2 = (x_1 - h)^2 + (y_1 - k)^2 - r^2.$$

The length along the tangent from a point (x_1, y_1) to the circle $x^2 + y^2 + Dx + Ey + F = 0$ is given by

$$t^2 = x_1^2 + y_1^2 + Dx_1 + Ey_1 + F.$$

The equation of the **tangent** to the circle $x^2 + y^2 = a^2$ at the point (x_1, y_1) is $x_1x + y_1y = a^2$.

The equation of the tangent of **slope** m to the circle $x^2 + y^2 = a^2$ is $y = mx \pm r\sqrt{1 + m^2}$.

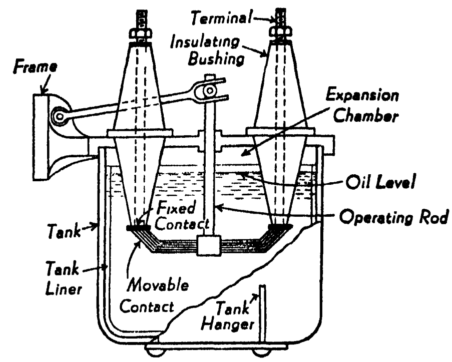
The circles $x^2 + y^2 + 2D_1x + 2E_1y + F_1 = 0$ and $x^2 + y^2 + 2D_2x + 2E_2y + F_2 = 0$ are orthogonal (intersect at right angles) if $2D_1D_2 + 2E_1E_2 = F_1 + F_2$. (L.L.S.)

CIRCLE OF POSITION. Line of Position.

CIRCUIT BREAKER. A circuit breaker is a special switching device for opening electrical power circuits under load, the operation being initiated either by an attendant, or automatically, in the event of abnormal circuit conditions. It is a safety device installed in those portions of an electric circuit where it is desired to open the circuit under load upon presence of abnormal current, abnormal voltage, high temperature, grounds, etc. There is no more important element of an electrical power system than the circuit breakers and their control equipment. They are used in generator leads, feeders, bus ties, large motor leads, etc. Ordinary switches cannot be used for such applications as they are incapable of extinguishing the resultant arc.

Circuit breakers may be classified as air break or oil break types. An air break type, commonly a carbon circuit breaker, consists of stationary contacts mounted on a vertical panel, a movable contact which is closed against a heavy spring by a handle, a trip to release the latch, and carbon auxiliary contacts which take the arc when the breaker opens. These breakers are mostly closed by hand, and opened by series overload trip coils. They are infrequently used above 600 volts. In recent years, a type of air circuit breaker called the Deion breaker has been developed. By means of magnetic fields the arc which tends to follow upon opening of a circuit under load, is deflected into a deionizing chamber where it is broken up into a number of short arcs which are deionized and quenched during a few cycles. The Deion breaker is applicable to a-c circuits.

The carbon circuit breaker is a type used principally for d-c circuits. The oil-immersed circuit breaker is standard with a.c. because the arc can be oil quenched as the voltage passes through the zero point. The accompanying figure shows the elements of an oil circuit



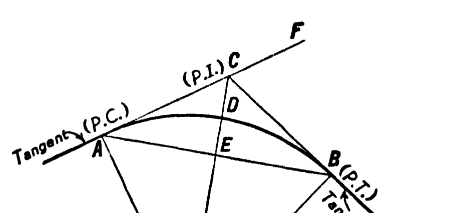
Oil circuit breaker.

breaker. The contacts are opened under oil by means of a rod extending through the cover of the case. The operating arm is actuated by hand, motor, or solenoid, and when in closed position is tensed by a heavy spring whose purpose is to produce a rapid opening of the contacts when the operating arm is released. The Deion principle is also applied to oil breakers. The latch which locks the operating arm in closed position against spring pressure may be tripped free by energizing a small solenoid called the trip coil, and the breaker has a protective device which is intended to be automatically opened by a trip coil actuated either directly by the current passing through the breaker, or indirectly by special trip circuits utilizing **relays.**

Recently special types of breakers have been developed. These employ various means such as oil impulses, pressure chambers, etc., to extinguish the arc. (F.T.M., L.R.Q.)

CIRCULAR CURVES. From a mathematical standpoint a circular curve is an arc having a constant radius but it is used in Civil Engineering as a general heading to cover simple, compound and reversed curves.

A circular arc joining two tangents (straight lines) is called a simple curve. Large radius simple curves are used in **highways** to provide a means of gradually changing the direction of the center line of a roadway.

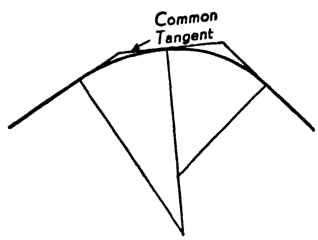


Simple Curve

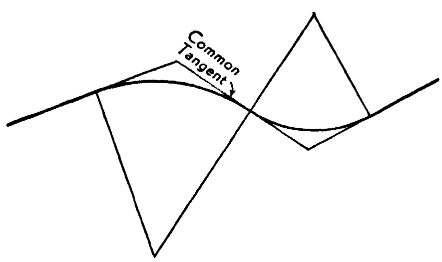
Simple curves connected by tangents were formerly used on railroads but they have been superseded by the combination of **spiral** and simple curves. The accompanying figure shows the elements of a simple curve.

Point A is called the point of curvature (P.C.) and point B the point of tangency (P.T.). Point C is known as the point of intersection (P.I.) of the tangents. In highway practice the length of the curve is generally represented by the length of the circular arc but in railroad practice it is given in terms of **chord** lengths.

A curve made up of two or more simple curves, each having a common tangent point at their junction and lying on the same side of the tangent, is called a compound curve. Compound curves have an advantage over simple curves since they may be easily adapted to the natural **topography** of a particular location.



Compound Curve



Reversed Curve

A curve made up of two simple curves, having a common point of tangency at their junction and lying on opposite sides of the common tangent is called a reversed curve. This type of curve is advantageous for use in connection with railroad cross-overs and spur tracks but should never be employed for main lines. Reversed curves are used in highway location when the alignment requires an abrupt reversal in direction. (C.W.C.)

CIRCULAR FUNCTIONS. **Trigonometric Functions.**

CIRCULAR MEASURE OF ANGLES. **Radian Measure of Angles.**

CIRCULAR MIL. This is a unit of area, employed to designate the cross-sectional area of electrical conductors. It replaces measurement in square inches, and is more convenient since it is not necessary to multiply by the factor π. A mil is 1/1000 of an inch. The area of a circle whose diameter is M mils is simply M^2 circular mils.

Wires are sized by their area in circular mils or by the American wire gauge. Despite the arguments in favor of one system using diameters in mils as size numbers, the American wire gauge is commonly used for wires sized from 40 to 0000 American wire gauge. Wires larger than 0000 (212,000 circular mils) are always sized in circular mils. (F.T.M.)

CIRCULAR MIL FOOT. **Resistance.**

CIRCULAR PITCH. **Spur Gearing, Worm Gearing.**

CIRCULAR POLARIZATION. **Polarized Light.**

CIRCULAR SECTOR. **Circle.**

CIRCULAR SEGMENT. **Circle.**

CIRCULATION. The distribution through the body of a liquid medium known as **blood** or haemolymph which conveys necessary materials to the tissues and carries wastes away from them.

In the simplest animals materials are merely transmitted from cell to cell but in the more complex forms the bulk of tissues which is removed from direct contact with the centers of interchange with the environment is too great to be served adequately by this method. In such animals a special **circulatory system** is developed for the more rapid distribution of materials. Circulation in such a system may be accomplished by the mixing of liquid contents in open cavities such as the **coelom** or it may be the function of special organs in closed tubular systems.

In a closed tubular system such as that of the **vertebrates**, including man, pressure is applied to the blood stream by a muscular organ, the heart, and by the muscular walls of the larger vessels. The blood leaves the **heart** under its greatest pressure and enters the arteries whose elastic walls expand and then, returning to their contracted state, partially equalize the fluctuating pressure supplied by the heart. The blood is at a lower pressure in the minute capillaries where some of it escapes into the spaces between the cells of other tissues; vessels of this kind occur in abundance at all points where interchange between the blood and the tissues takes place. From the capillaries the blood flows back to the heart in veins. In total, the pressure diminishes steadily from the time the blood leaves the heart until it returns again, a necessary condition according to the laws of hydraulics.

The relations existing at any point in the body between the liquids in the cells and intercellular spaces and the blood itself make possible osmotic (see **osmosis**) interchange in both directions which serves the needs of the tissues and maintains a normal concentration of materials in solution in the blood.

The paths of circulation in the bodies of various animals involve the discussion of the **circulatory system.** (A.W.L.)

CIRCULATION, AERODYNAMIC. A mass of air in rotary motion is said to be in circulatory flow if its velocities at various radii from the center of rotation are of the proper magnitude to induce radial equilibrium of the circulating mass. Consideration of the requirements for equilibrium consists in balancing centrifugal forces against static pressures derived from **Bernoulli's Theorem** and results in the specification that velocity of a particle must be inversely proportional to its radius from the center of rotation. Note that this is not like the motion of portions of a wheel, whose velocities are proportional to their radii. A simple case of circulation could be visualized as the flow pattern (concentric circles) induced by a rough cylinder rotating rapidly in still air.

If air is in circulation and no object such as a cylinder occupies the central core the velocity at the center of rotation reaches a theoretical value of infinity. This is impossible and the center of circulatory flow must be occupied by a small core of air in simple rotary motion. Air in this condition is described as a free **vortex.** Exceptionally high velocities may exist at the edge of the rotary core, and in vortices of high circulatory strength such as tornadoes the atmospheric energy may reach destructive proportions.

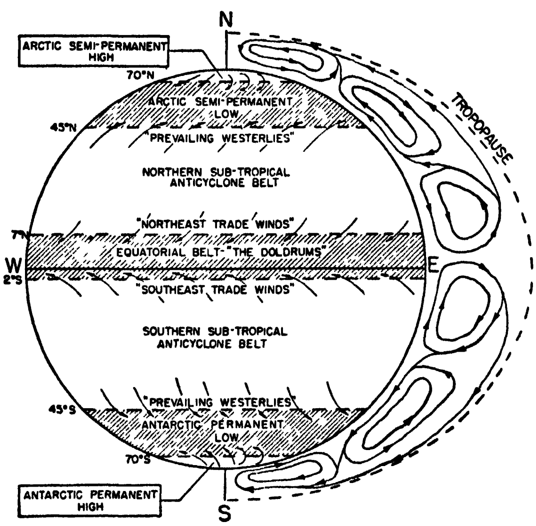
The strength of aerodynamic circulation (usually called the *circulation* and designated by symbol Γ) is the line integral of the tangential component of the velocity along any closed line encircling the vortex center, or some object.

$$\Gamma = \oint v\,dl.$$

It has been proven that Γ has the same value for any closed path through the flow around the object (such as an airfoil, cylinder, etc.) and this fact is of value in various phases of aerodynamic analysis. A simple case of a flow pattern of concentric circles illustrates the constancy of Γ. The velocity at radius r is $\frac{K}{r}$ and $\Gamma = \oint \frac{K}{r}\,dl = \oint \frac{K}{r}\,r\,d\theta = 2\pi K$. Therefore Γ is not a function of r; its magnitude is constant throughout the flow pattern. (F.T.M.)

CIRCULATION OF THE ATMOSPHERE. When averaged over long periods of time, local and small-scale irregularities in the atmosphere's motions disappear and a generalized pattern of winds is manifest. There are five latitudinal belts in each hemisphere into which generalized winds can be classified.

1. The Doldrum belt which extends roughly from the equator to 10 or 15° north and south is a belt of light variable winds.
2. The Trade Wind belt extends from 10 or 15° north and south to approximately 30° north and south. Trade winds blow from the northeast to east-northeast in the northern hemisphere and from the southeast to east-southeast in the southern hemisphere and are known respectively as the Northeast Trades and the Southeast Trades.
3. A narrow and drifting belt of light variable winds extends about the earth at approximately 30° north and south. This belt is known as the Horse Latitudes.



General circulation of the earth's atmosphere. (*Halpine's A Pilot's Meteorology.*)

4. Westerly winds with a slight component from the south blow in a relatively wide band from approximately 30° north and south to 60 or 70° north and south. They are known as the Prevailing Westerlies but in the southern hemisphere are more commonly known as the Roaring Forties because of their stronger and more steady character.
5. The polar area winds tend to blow anticyclonically with an easterly component over each region.

Surface atmospheric pressure belts fit these surface wind zones. There are four distinct zones or belts of high and low pressure.

1. Pressure in the doldrums is low.
2. Pressure in the horse latitudes is high.
3. Pressure between the temperate-zone westerlies and the polar winds is low.
4. Pressure over the polar caps is high.

Two well-developed semi-permanent cyclones are present in the northern hemisphere, one located over the North Atlantic near Iceland, known as the Icelandic Low, and the other in the Aleutian area of Alaska, known as the Aleutian Low. In the southern hemisphere there is a more or less continuous belt of low pressure around the world at the corresponding latitude.

Because pressure decreases more rapidly with altitude when air is cold, surface-wind characteristics disappear very slowly with altitude and at considerable height the circulation is generally westerly.

There is considerable change in the general circulation from winter to summer in so far as continents and oceans are concerned. These seasonal winds, or changes in the general circulation, are known as monsoon winds. Over the United States and Canada, the average wind directions during winter are west and north. This brings relatively warm air in over the Pacific coast but cold Polar air to the area east of the Rockies. During summer, winds on the Pacific coast remain from the west and north bringing relatively cool air to this region. East of the Rockies, winds are west and south bringing hot and often humid air over the entire section. Because of these monsoon winds, seasonal temperature changes in the eastern parts of North America are considerably greater than changes in solar radiation would indicate. Monsoons are extremely well developed over India and southeastern Asia where they are hot and rainy during summer and cool and dry during winter. A major seasonal change is the migration of the equatorial and subtropical circulations (doldrums, horse latitudes, and trade winds) north and south with the sun. This also causes weakening of the westerlies during summer and strengthening during winter; weakening of the Icelandic and Aleutian Lows during summer and a weakening of the Polar circulations in summer.

Winds can be divided into four categories:

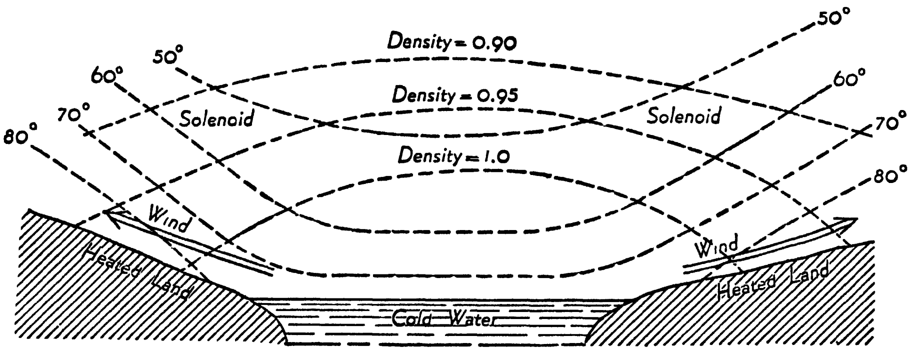
1. Gradient winds blow in accordance with the existing pressure gradient centrifugal force and Coriolis Force.
a. Cyclonic winds blow counterclockwise about regions of relatively low pressure in the northern hemisphere and clockwise in the southern hemisphere.
b. Anticyclonic winds blow clockwise about regions of relatively high pressure in the northern hemisphere and counterclockwise in the southern hemisphere.
2. Geostrophic winds blow in accordance with the pressure gradient, but only where the pressure gradient is balanced by the Coriolis Force. They are, therefore, winds which blow in straight or nearly straight lines over the earth. Geostrophic winds are not possible at the equator because there is no Coriolis Force present.
3. Cyclostrophic winds blow cyclonically in both hemispheres in wind systems where the pressure gradient is balanced by centrifugal force in the absence of the Coriolis Force. Cyclostrophic winds occur near the equator as hurricanes and other local less intense vortices.
4. Antitriptic winds are small-scale, short duration winds which blow, in general, along the pressure gradient. Land and sea breezes are of this type.

In general, winds are mainly gradient winds.

Many strictly local winds blow over relatively small regions. Most of these occur where there is sharp contrast in surface temperature over a relatively small distance or where terrain is highly irregular. Sea breezes blow from cool water to heated land during the heat of day. Land breezes blow from cooled land to warmer water during the cool of the night. Valley breezes blow upslope in valley-hill terrain during sunny days, and mountain breezes blow downhill in a reverse manner during darkness. Mountain breezes often become very strong and extremely variable as a result of large-scale eddies and Venturi effects in mountain passes. (P.E.K.)

CIRCULATION THEOREM. If the atmosphere is baroclinic, that is, if the surfaces of equal pressure and equal density intersect at any angle whatsoever, there is

a tendency for a circulation to develop in such a manner that the atmosphere will become barotropic, that is, the surfaces of equal pressure and equal density will coincide. The atmosphere is normally baroclinic. Sea and land breezes, mountain and valley breezes are results of well-defined baroclinic states. Direction of circulation is always such that cold air flows toward warm air at the base of the circulation pattern, and warm flows toward cold at the top of the pattern. Air sinks in the cold air region and rises in the warm air region. Thus the sea breeze blows along the surface of the earth from cold water to heated land, rises, then returns seaward and sinks.



Circulation theorem and solenoids.

It is possible to compute the magnitude of the circulation from a given baroclinic state if temperature and pressure are known. Suppose a vertical plane were erected perpendicular to a shore, extending from the cold water to heated land. Lines of equal pressure and temperature drawn in this plane will produce a field of approximate parallelograms which are known as solenoids. A tendency for circulation exists about the perimeter of each solenoid, but in the field as a whole this tendency is nullified in adjacent solenoids. There is no nullification along the border solenoids of the whole field and it is here that the circulation springs up. The number of solenoids in the field is a measure of the expected strength of the resulting circulation. (P.E.K.)

CIRCULATORY SYSTEM. The system of passages and chambers through which materials are distributed in the body in a liquid mixture called **blood** or haemolymph.

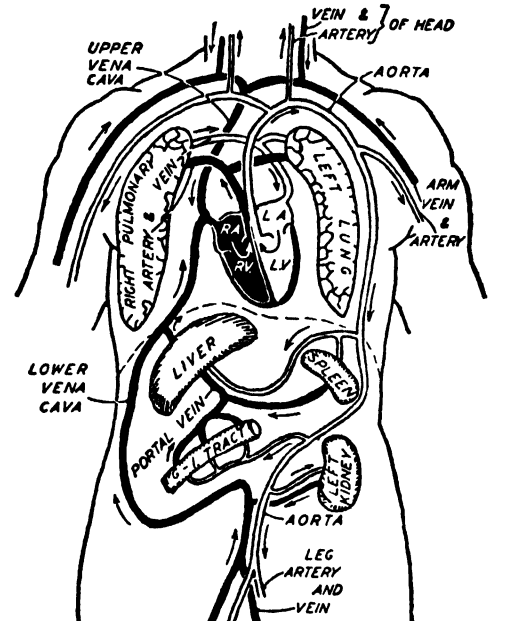
Animals of very simple structure and small size secure adequate distribution by the diffusion of materials from cell to cell and so have no need for a special circulatory system. In more complex bodies, however, the principal centers of interchange, such as the alimentary tract, respiratory organs, and excretory system, are far removed from some of the parts that they serve; here more rapid transportation is necessary.

This need is met in some animals by the extension of centers of interchange. In the flatworms, for example, the alimentary tract branches through the body and no other structure is far from some part of it.

Other forms, as the roundworms, have extensive spaces within the body in which liquid contents are moved to some extent by the movements of the body. This type of circulation extends to animals with a true body cavity or **coelom** but here it is associated with the development of a closed tubular circulatory system, a condition which exists in the earthworm.

In this simple state the tubular system consists of a longitudinal vessel above the alimentary tract and others at different levels in the ventral part of the body. Other tubes running around the alimentary tract associate the longitudinal vessels, and muscular walls of certain regions, together with valves in the cavities of the tubes, propel the blood which they contain. In the earthworm the contracticle vessels are principally the dorsal vessel and a series of five pairs encircling the **oesophagus** and known as hearts. The blood flows forward in the dorsal vessel, down through the hearts, and back in the ventral vessels, reaching the dorsal vessel again after following various routes through the tissues which it serves.

In such systems as this several types of vessels are developed. Those which lead from the central pumping organ receive the blood under its highest pressure and have the strongest walls, containing elastic and muscle fibers. These vessels are called arteries. They lead into



Circulatory system. (*Carlson & Johnson's The Machinery of the Body, University of Chicago Press.*)

smaller branches known as arterioles and these in turn into minute vessels with very delicate walls made up chiefly of a single layer of thin cells. In the human body these delicate **capillaries** are from 1/200 to 1/80 mm. in diameter. Some of the blood-fluid passes between the cells of their walls into spaces in the surrounding tissues where interchange with the various cells is possible. In some parts of the body, as in the liver of vertebrates, the ultimate tubular passages are even simpler than the capillaries and are called sinusoids. Their walls are, at least in part, merely the surrounding tissues; whether a special lining exists in some parts is disputed. From such small vessels the blood is col-

lected into veinlets and these converge to form veins which carry it to the heart. The veins have strong walls of complex structure but in vessels of the same caliber the walls are thinner in veins than in arteries.

Some of the fluid from tissue spaces is gathered into a type of vessel resembling veins but more delicate; it flows into trunk vessels which rejoin the veins. This system of vessels is known as the lymphatic system.

In the vertebrates the fishes present the basic plan of the circulatory system. The **heart** has two principal chambers, an **atrium** which receives the blood and a **ventricle** which pumps it out to the body. A single large artery, the ventral aorta, leads forward and branches into a series of afferent branchial arteries which break up into capillaries in the gills. Efferent branchial arteries lead out of the gills to the dorsal aorta which runs back to the body. The head is supplied by extensions of the dorsal aorta, the carotid arteries. From the arterial system branches conduct the blood to the capillaries of all parts of the body. The blood from the alimentary tract is collected into a hepatic portal vein which breaks up into sinusoids in the liver, and is carried thence to the heart by a hepatic vein. In a like manner some of the blood from the caudal part of the body is conveyed to the **kidneys** by a renal portal vein before entering the veins which carry it to the heart. From all other regions of the body the blood is collected by veins which flow directly to the heart.

The **vertebrate** heart is a specialized region of the tubular system whose subdivision into chambers is complicated above the fishes by some degree of longitudinal splitting. In the **amphibians** the atrium has become two, right and left, in the **reptiles** the splitting involves the ventricle, and in the birds (**Aves**), and **mammals** the division into four chambers is complete. Blood entering the right auricle comes from the body and passes on into the right ventricle to be pumped to the lungs. It returns by the pulmonary veins to the left auricle, enters the left ventricle, and is pumped to the body. In other respects the most striking difference between the circulatory system of the fish and that of man is the elimination of the renal portal system in the higher classes of vertebrates.

The circulatory system of **arthropods** differs from that of other complex animals in the limited extent of the closed tubes and their association with extensive blood spaces constituting a haemocoele or blood cavity. **Insects** have a single longitudinal tube lying in the dorsal region of the body. It pumps the blood into the head and is known as the heart or dorsal vessel. (A.W.L.)

CIRCUMCISION. The excision of the foreskin or prepuce which covers the head of the **penis** in the male. The operation is indicated when the foreskin is too tight, although it is often done solely for cosmetic purposes. Circumcision is performed as a religious rite on both sexes by some races. (R.S.M., D.M.H.)

CIRQUE. Topographic feature produced by a mountain glacier. A mountain glacier usually starts in some sheltered ravine, slightly below the top of the mountain. Névé (firn) is the name of the granular ice which gradually develops from the original snow. The névé or accumulation of ice is restricted to that altitude at which the average summer temperature is 32° F. This line (summer **isotherm**) may vary from sea level, in the polar regions, to 20,000′ in the tropics. After the accumulation of granular ice on a slope reaches a certain thickness, the mass moves slowly downward under its own weight, by a process of plastic flow. In the névé region, where the snow and ice bank rests against the sloping cliff, the ice tends to work away from the rock, forming a crevice called the bergschrund. Frost action in the region of the bergschrund causes the recession of the cliff, the broken material from which is frozen into the base of the ice and serves as tools to scour out circular basins called cirques. Small lakes and ponds which occur in cirques are called tarns. Where several cirques are developed near the summit of a mountain, the side walls of the cirques are called combs; the ridges between the cirques, cols; and the elevated terminations of the comb ridges, monuments. A triangular mountain peak, such as a Matterhorn, results from the complete cirquation of what was originally a relatively smooth-topped mountain. (R.M.F.)

CIRRHOSIS. A chronic disease of the **liver** characterized by gastrointestinal symptoms, **jaundice**, enlargement of the liver and spleen, and **ascites.** Pathologically, there is destruction of liver cells and overgrowth of fibrous **connective tissue.** If the cell destruction radiates from the center of the lobule the cirrhosis is classified as portal; if the periphery of the lobule and the interlobular biliary passages are primarily involved, the term biliary cirrhosis is used.

1. Portal cirrhosis, or Laennec's cirrhosis, is by far the commoner type. It occurs more often in men than in women, and usually in the 4th and 5th decades. It was formerly believed to be due to excess ingestion of alcohol ("gin-drinker's liver") since approximately 75% of cases occur in alcoholics. Now, however, **Vitamin B** deficiency is thought to be the major factor, and alcohol is considered to be secondary in importance. In a certain number of cases, where vitamin B deficiency plays no apparent role, a variety of etiologic agents may be involved. These include infections such as schistosomiasis (fluke infestation) and **syphilis,** and chemical poisons, including **carbon** tetrachloride, cinchophen, **phosphorus** and **arsenic.**

The symptoms and signs of portal cirrhosis are variable. Rarely, they may be absent in well-marked cases. The contraction of the fibrous tissue of the liver causes obstruction of the venous blood from the abdominal organs, and consequently congestion of the gastric and intestinal mucosa. As a result, **anorexia,** nausea, and vomiting are common. As the obstruction of the vessels progresses, the veins dilate to form varices, and may rupture into the stomach and produce a massive, frequently fatal, **hemorrhage.** Bleeding from **hemorrhoids,** which are also the result of back pressure from obstruction, is common. Patients with cirrhosis are sallow, anemic and, late in the disease, jaundiced. **Ascites** occurs in 80% of cases and as many as 12–15 liters of fluid may distend the abdomen. Peripheral **edema** and enlargement of the liver and spleen are common. Many patients have a low-grade fever.

The treatment of portal cirrhosis consists of a high-caloric, high-protein diet, and supplementary vitamin B complex, as brewer's yeast or thiamine chloride and nicotinic acid. Liver extract is also recommended. If ascites is present, fluid may have to be removed by repeated abdominal taps and drainage. If the disease is treated before ascites appears, the prognosis is better, although marked improvement may occur even after ascites has developed. The disease usually runs 3 to 6 years, but 2 years is the average duration of life after signs of liver failure such as ascites, jaundice, and **hematemesis** appear.

2. Biliary cirrhosis. Two forms of biliary cirrhosis occur, a primary and secondary form. The first is uncommon and is characterized by enlargement of the liver and the **spleen** with the presence of **jaundice.** Infection is the most probable cause. The disease cannot be arrested and the average duration of life is 5 or 6 years.

The secondary biliary cirrhosis is an obstructive type of cirrhosis caused by occlusion of the bile duct by **gallstones** or **tumor** formation. Jaundice is present with recurring attacks of chills and high fever. Treatment is surgical. (R.S.M., D.M.H.)

CIRRIPEDIA. **Crustaceans** of which the only commonly known representatives are the **barnacles.** The name applies to a subclass characterized by adaptations for sessile life; the included species are unlike other crustaceans in appearance.

Economically the barnacles are important because they attach themselves to the bottoms of ships and necessitate occasional removal.

Classification:

Order Thoracica. The common **barnacles.**

Order Acrothoracica. Small forms of which the females live in cavities in the shells of mollusks.

Order Apoda. One simplified form, parasitic in a common barnacle.

Order Rhizocephala. Parasitic, usually on crabs and related crustaceans. The adult forms root-like growths in the body of the host and is otherwise degenerate in form.

Order Ascothoracica. Parasitic in corals; less degenerate than the preceding. (A.W.L.)

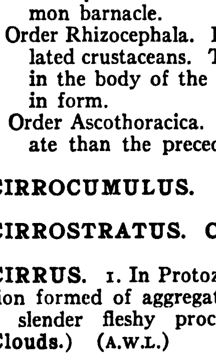
CIRROCUMULUS. **Clouds.**

CIRROSTRATUS. **Clouds.**

CIRRUS. 1. In Protozoa a spine-like organ of locomotion formed of aggregated **cilia.** 2. In **annelid** worms a slender fleshy process on the **parapodia.** (See **Clouds.**) (A.W.L.)

CISCOE. Pisces, Teleostei. *Leucichthys.* Important food fishes (**Pisces**) of the Great Lakes and a few smaller lakes. Also known as the lake herrings. Included are two species known as **long-jaws,** the **bluefin** or blackfin, one species which is called the cisco, *Leucichthys hoyi,* and the **tullibee** which is found in smaller lakes in the Great Lakes region. (A.W.L.)

CISSOID OF DIOCLES. The cissoid is a type of mathematical curve which was first studied by the ancient Greek mathematician Diocles.



Cissoid.

The cissoid is a **plane curve** which may be defined geometrically as follows: Draw a circle of radius a with its center on the X-axis and passing through the origin of a system of **rectangular coordinates.** Draw the **tangent** to the circle at A, where the circle cuts the X-axis. Let any secant line OS cut the circle at R and the tangent at A in the point Q; then lay off $OP = RQ$. The locus of the point P as the secant rotates about O is the cissoid.

In **polar coordinates,** the equation of the cissoid is $r = 2a \sin^2 \theta / \cos \theta$. In **rectangular coordinates,** the equation is

$$y^2 = \frac{x^3}{2a - x} \quad \text{or} \quad x^3 + xy^2 - 2ay^2 = 0.$$

The cissoid can be used to "duplicate a cube," i.e., to find the edge of a cube whose volume is twice that of a given cube. (L.L.S.)

CITRAL. **Aldehydes, Ketones, and Related Compounds.**

CITRIC ACID AND CITRATES. Citric acid ($H_3 \cdot C_6H_5O_7$ or $COOH \cdot CH_2 \cdot C(OH)(COOH) \cdot CH_2 \cdot COOH \cdot H_2O$) is a white solid, water of crystallization lost at 130°, melting point 153° C., decomposes at higher temperatures, soluble in water or alcohol, slightly soluble in ether. Citrates (like tartrates) in solution change silver of **ammonio-silver** nitrate into metallic silver. **Calcium** citrate on account of its solubility characteristics, is of importance in the separation and recovery of citric acid. Calcium citrate plus dilute sulfuric acid yields citric acid plus calcium sulfate, and the latter may be separated by filtration. Citric acid may be obtained by evaporation of the filtrate. Citric acid may be obtained (1) from some natural products, e.g., the free acid in the juice of citrus and acidic fruits, often in conjunction with **malic** or **tartaric** acid, and the juice of unripe lemons (approximately 6% citric acid) is a commercial source; (2) by the **fermentation of glucose;** (3) by synthesis. Citric acid is a tribasic acid, that is, three series (mono-, di-, tri-) of salts and esters are known. Citric acid is used (1) in effervescent beverages, and effervescent medicinal salts, e.g., "citrate of magnesia," consisting of citric acid, sodium hydrogen carbonate and magnesium sulfate, (2) as ferric ammonium citrate in **blue printing.** (R.K.S.)

CITRINE. The mineral citrine is a yellow variety of **quartz** sometimes used as a gem. It is often marketed under the name topaz and may mislead the unwary. Brazil and Madagascar have furnished material of excellent quality. (E.S.C.S.)

CITRON. **Citrus Fruits.**

CITRONELLA. **Volatile Oils.**

CITRONELLAL. **Aldehydes, Ketones, and Related Compounds.**

CITRUS FRUITS. Rutaceae. The various Citrus fruits are obtained from thorny shrubs or small trees, having smooth leathery evergreen leaves with numerous internal resinous glands which contain an aromatic oil. In most of the species the **petiole** of the leaf has winged margins and is articulated both to the branch and to the blade. The flowers are extremely fragrant and are usually pure white, or in some species purplish pink. They are borne singly or in small **cymes** in the axils of the leaves. The **calyx** has 3–6 small teeth, the **corolla** is composed of 4–8 thick petals, while there are numerous **stamens** and a many-celled **ovary.** The fruit of these plants is a modified **berry,** known as a hesperidium.

The roots of Citrus plants lack root hairs entirely, absorption being directly through the fine terminal fibrous roots. The wood is hard and fine grained.

All Citrus plants are native to the Old World. The principal species in cultivation are as follows:

Citrus trifoliata, or the trifoliate orange, has trifoliate leaves, and hairy useless fruit. Its importance is due to its hardiness, making it valuable for hybridizing with more desirable species. It can be grown outdoors as far north as southern New York State.

Citrus sinensis, the Orange, originating in China, and with many varieties, is widely cultivated. In this country two principal growing regions exist, with characteristic varieties in each. Florida produces sweet, thin-skinned juicy oranges, which ripen in early winter. They are picked before fully ripe and matured in storage. California produces thick-skinned navel oranges (see **Parthenocarpy**), which have a pleasing acid pulp, and ripen during the winter and spring months. The source of these navel oranges was a sport arising in Brazil, and later carried to California, where it was extensively propagated. California also produces the many-seeded Valencia oranges, which ripen from June through October, producing a crop when other varieties are not in bearing.

Citrus Limonia, the Lemon, is probably a native of India. The trees are small and have many stout thorns. The flowers are large and purplish. The plants are not at all hardy, so are grown only in regions entirely free

from frost. The fruits are produced continuously throughout the year and are picked green. To allow them to ripen on the tree causes them to become bitter and unmarketable. As soon as they attain the size demanded by the market they are picked and stored, often for several months. Coloring gradually develops during storage, or may be hastened by placing them in rooms heated above 90° F., where the yellow color develops in four to five days.

Citrus paradisi, Grapefruit, is probably derived from a bitter-fruited Malaysian tree. This is the largest fruited of all the Citrus plants. The trees are somewhat hardier than orange trees, and are principally grown in Florida.

Citrus nobilis, King oranges, Mandarin oranges, Tangerines. This species is characterized by the ease with which the skin or rind is removed from the sweet pulp.

Citrus aurantifolia, Lime, are very thorny shrubs or small trees, which are not at all hardy, and so are grown mainly in tropical countries and, in the United States, in California and the southern tip of Florida. The white flowers are small, as is the very acid thin-skinned fruit.

Citrus medica, Citron, is rarely grown in the United States. The rind of the fruit is treated with brine to remove the bitter oil it contains, then boiled in a sugar solution to which glucose (see **Carbohydrates**) has been added. The glucose is used to keep the product from becoming brittle. After boiling for a short time the rind remains in the syrup for a few weeks. It is then removed, boiled once more in pure sugar solution and dried. It is now the commercially-marketed citron.

Citrus Aurantium, Bitter or Sour Orange, is an ornamental tree, which is cultivated as a stock on which to bud other more desirable forms.

Citrus Bergamia, bergamot.

Related to the Citrus group is the genus *Fortunella,* with several species. They are the kumquats. They are small evergreen shrubs often planted for ornament and because of the small yellow fruits, which are either eaten raw or used in preserve making. In addition to the species enumerated, many hybrids have been developed.

The citrus industry of the United States has received many setbacks during its history. An ever-present source of worry is the danger of frosts, which are fatal to the present crop, and often do serious damage to the growing trees. At times frost injury is so serious as to menace the success of the industry. The use of smudge pots, producing clouds of smoke, increasing the humidity of the air by irrigation and other procedures are a partial insurance against damage.

Recently Florida has been beset with the Mediterranean **fruit fly,** which attacks a variety of fruits, in addition to the citrus varieties. This pest is now declared to be eradicated. Citrus canker, a bacterial scourge, is another source of destruction of the Florida crop. In California, very undesirable **scale insects** are present.

The uses of citrus fruits are many and varied. A very large part of the crop is consumed as raw fruit or as a drink. The rich **vitamin** content they possess has done much to further their consumption. Citrus oils and **citric acid** are by-products from culled fruit, which are becoming of commercial importance in the United States. The oils are largely used in flavoring extracts, and to some extent in perfumes and soaps. (R.M.W.)

CITY SURVEYING. Surveying.

CIVET. Mammalia, Carnivora. Animals of slender build with long tails and short legs, somewhat like the weasels in appearance. They occur in Africa, southern Europe, and southeastern Asia and constitute the family Viverridae including, in addition to the true civets, species known as **genets, linsangs,** palm-civets, the **binturong,** the mongooses, hemigales, and a few related forms.

The name is also applied to the **cacomistle** and locally to the small spotted **skunk** of North America. (A.W.L.)

CLADOCERA. The water-fleas, an order of small **crustaceans.** (A.W.L.)

CLADOSELACHE. Fossil Fishes.

CLADOSICTIS. Miocene.

CLAIRAUT'S DIFFERENTIAL EQUATION. Ordinary Differential Equations of First Order and Higher Degree than the First.

CLAM. Mollusca, Pelecypoda. Any member of numerous species of **bivalve** mollusks; a mussel. Some species are commonly called mussels, others clams, and in some

Anatomical model of hard shell clam. (*American Museum of Natural History.*)

cases the names are freely interchanged. Thus the edible mussel and other members of the same family receive this name only, the little-neck clam is always a clam, and the fresh-water species are called freely both clams and mussels.

The clams are moderately important as food. Occasionally valuable pearls are found in them and the shells of fresh-water species are the foundation of the important pearl button industry of the Mississippi Valley. (A.W.L.)

CLAM WORM. Annelida, Polychaeta. Marine worms of the genus *Nereis.* (A.W.L.)

CLAPEYRON'S EQUATION. This is a very useful differential equation involving the variables associated with the transition of a pure substance from one state to another; that is, from solid to liquid, liquid to vapor, or solid to vapor, and vice versa.

If the variables of state used to represent the condition of the substance are the absolute (Kelvin) temperature T, the pressure p, and the specific volume v, the equation may be written

$$\frac{\partial p}{\partial T} = \frac{L}{T(v_2 - v_1)}, \tag{1}$$

in which L is the heat of transition, that is, the heat evolved or absorbed, per unit mass, during the transition. v_1 and v_2 represent the specific volumes of the substance before and after the transition, respectively. If we use temperature, **entropy** (ϕ), and specific volume as the variables, the equation takes the form

$$\frac{\partial \phi}{\partial v} = \frac{L}{T(v_2 - v_1)}. \tag{2}$$

For a transition taking place at some specified fixed temperature T, the common second member of these equa-

tions becomes a known constant, whose value represents the slope of either the T-p or the v-ϕ transition curve, at the point of transition. In other words, it shows the rate at which one variable must change with respect to the other in order to maintain equilibrium between the two states at the given temperature.

For example, we may use Eq. 1 to calculate the change of the boiling point of a liquid with pressure in the vicinity of its normal boiling point.

Take the case of water near 100° C. The absolute temperature corresponding to 100° C. is $T = 373°$. The heat of vaporization of water at this temperature is $L = 540$ cal./g. $= 2.26 \times 10^{10}$ ergs/g. (see **Mechanical Equivalent of Heat**). The specific volumes of steam and of water at this temperature are respectively $v_2 = 1671$ cm.^{3}/g. and $v_1 = 1$ cm.^{3}/g. Substituting these values in (1) we obtain $\partial p/\partial T = 36{,}260$ ergs/deg. cm.^{3} = 36,260 dynes/cm.^{2} deg. = 27.2 mm. Hg/deg. The reciprocal of this, $\partial T/\partial p = 0.368$ deg./mm. Hg, is the quantity required. That is, near normal pressure the boiling point of water rises at the rate of 0.368° per mm. of pressure. This result agrees closely with experiment.

Many other applications of Clapeyron's equation are encountered in the thermodynamic treatment of changes of state. (L.D.W.)

CLARAIN. A term proposed by Marie Stopes in 1919 for a finely banded variety of "bright" or shiny bituminous coal. In thin sections, under the microscope clarain is seen to be composed of disintegrated plant substances including bands of **spore** cases, which impart a yellowish to reddish color to the substance. (R.M.F.)

CLARIFICATION. **Filtration.**

CLARK CELL. **Standard Cell.**

CLASS. The second subdivision of the animal kingdom: major subdivisions or **phyla** are divided into **classes.** (A.W.L.)

CLASS INTERVAL. **Class Limits.**

CLASS LIMITS. Class limits are of two types, open and closed. The open class limits are determined by the degree of accuracy with which the **variable** is measured. If measurements of the variable have been made to the nearest ¼ inch, then the open class limits might be 10–14.75 inches, 15–19.75 inches, etc. The open part, λ, in this case ¼ inch, is the inaccuracy in the measurements. The closed class limits are found by subtracting $\lambda/2$ and adding $\lambda/2$ respectively to the lower open class limit and the upper open class limit. In our example the closed class limits would be 9.875–14.875″, 14 875–19.875″, etc. The class mark in either open class limits or closed class limits is the sum of class limits divided by 2. The class interval, c, is the difference between successive class marks, or the difference between successive lower closed class limits, or it may be found in various other ways. The class interval should be kept constant, if possible, in a **frequency distribution.** (L.A.A.)

CLASSIFICATION. Classification is the separation of a mixture of substances of various sizes and specific gravities into two or more divisions, the cuts being made both with reference to size and to specific gravity. There are three general classes:

1. Sorting classifiers; using a relatively dense aqueous suspension as the fluid medium. These species of equipment make more than two cuts and use hindered settling as the means. The cuts contain material settling at the same rate in the dense medium. Each cut contains material of more than one density and more than one size. The relative distribution is coarse-light and fine-heavy. This makes excellent tabling feed. Feed is from 0.05 mm. to 5 mm. (or larger for coal). They have little use outside the metallurgical field.

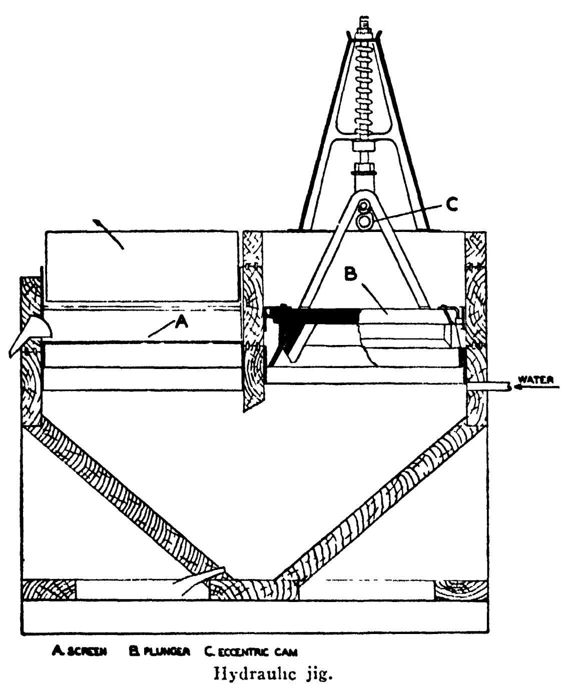
2. Sizing classifiers; make only a single separation, coarse from fine, but often this is a separation of densities also, as clay from sand. They are merely settling tanks. The fine particles overflow and the coarse settle. Provision is made for removing the coarse particles and cleaning them by several turn-overs. This process is often used in connection with closed circuit grinding. The feed can vary over wide limits. Drag classifiers dewater and raise the coarse material, thereby doing three jobs at once.

3. Air classifiers; produce two grades of material, coarse and fine. Utilizing centrifugal force and gravity, the coarse material is made to fall into receivers while the fine is blown out. This classifier is also used largely in connection with closed circuit grinding.

Efficiencies of classifiers based on screen analyses range from 50 to 80% but would be much higher if based on settling rates. Cost of treatment is about 1 cent per ton of material. Classification, except in closed circuit grinding, has been replaced to a large extent by flotation.

Tabling is a classification based on the stratification of particles in a liquid stream. Coarse-heavy and fine-light come off together, the opposite of hindered settling, so that these two processes in series can make good separations. 10-micron to 10-mesh particles can be treated. Larger sizes can be worked if the material is coal. Density, size, and shape of particles are the determining factors. The average cost of processing is 5 to 10 cents per ton of material.

Jigging is the consolidated result of three effects; hindered settling, differential acceleration at beginning of fall, and consolidation trickling at end of fall. The result is that an almost complete separation with respect to densities can be obtained. Jigs fall into two general classes, depending on how they are constructed, namely, (1) the movable screen type, and (2) the vibrating liquid type. For materials too fine for regular jigging, the same results can sometimes be obtained by putting a layer of fine shot on the screen which acts as the classifying layer. Jigs are used only on fairly coarse material, and



A. SCREEN B. PLUNGER C. ECCENTRIC CAM
Hydraulic jig.

so are well adapted to treating coal. Their use in other fields is largely being replaced by flotation. They are cheap and simple of operation but require much water and fairly expert handling.

Flotation is the best way (when it is possible) of separating different substances. The results are based on preferential wetting or non-wetting of the materials. The separation is accomplished by allowing one material to sink (wetted) and the other to float off (non-wetted) as foam. The wetted material must be coarse enough to sink and the non-wetted must be fine enough to be floated. As both materials are ground together, a proper size balance must be maintained. In general, with the exception of coal, the material is fairly fine. The foam is made by air bubbles, the air being either beaten in by stirrers or blown in below the liquid level. The maximum concentration of material in the feed varies with the material in question, the highest being about 40%. Several ingredients are added to assist in the separation, thus: 1. Frothers—to make foam (0.025–0.25 lbs. per ton). 2. Collectors—to give a preferential wetting effect (0.05–2.5 lbs. per ton). These collectors are usually large organic molecules partly soluble in water, and partly insoluble. 3. Hydrocarbon oils—to protect films (1.0–5.0 lbs. per ton). 4. pH regulators—(0.5–10 lbs. per ton). 5. Activators—to change the surface effects so that the collector will work better (0.5–2.0 lbs. per ton). 6. Depressants—to reduce the activity of one substance to the advantage of another (0.05–1.01 lbs. per ton). 7. Deactivators—when the activator works on both materials, a deactivator is used to destroy its effect on one of the materials (0.05–0.5 lbs. per ton).

These reagents are seldom all used at the same time but various combinations may be found desirable. Theoretically, flotation can be applied to any two materials, it is necessary only that the right flotation reagents be found. Except for a few generalizations, the reagents are determined largely through trial and error. The usual flotation process is a combination of several cells in series and in parallel, arranged to give the best separation.

Thickening is merely the settling out, by gravity, of the solid material in a slurry, followed by the mechanical removal of the settled (thickened) solid. Any material that sinks in its liquid vehicle can be thickened. Fairly exact equations for settling rates are known so that small-scale tests can be used in the calculation of large-scale equipment. Good theory can be applied both to the free settling period and to the intermediate and impeded periods, although the taking of the data is an art.

Thickeners have low power consumption, require practically no attendance and can be obtained in a wide variety of sizes and capacities. They are usually used on thin suspensions of fine materials such as slimes or flocs where settling time is high. They are almost all built on the principle of a wide tank, with the flow in the middle, so designed that all the solid has settled below the overflow level by the time the liquid has reached the edge and only clear liquor overflows. The solids are moved by various types of arms to the center sump at the bottom of the tank and carefully pumped out. Thickeners are very efficient, easy to operate, and very low in cost of maintenance. Because of their simple construction they can be made of almost any desired material, and can therefore handle corrosive liquids. (See **Filtration.**) (D.E.M.)

CLASSIFICATION OF ORGANISMS. The description of kinds of living things and their arrangement in categories of various rank according to relationship of varying degrees as determined by the available knowledge of their structure and functions.

The classification of organisms is the function of the science of **taxonomy.** By common agreement under the principles of this science the organic world is now divided into plant and animal kingdoms, and in the animal kingdom the following series of subdivisions is recognized:

Phylum
    Class
        Order
            Family
                Genus
                    Species

Various other divisions are introduced into some classifications to express other degrees of relationship. Terms used in this way are subclass, suborder, section, superfamily, subfamily and group.

Agreement is lacking on a few small divisions of the animal kingdom, but most of the phyla into which it is divided are generally accepted. The following is a classification commonly used.

Phylum **Protozoa.** The 1-celled animals.
Phylum **Porifera.** The **sponges.**
Phylum **Coelenterata.** The **hydroids, jellyfishes, corals, sea anemones,** etc.
Phylum **Ctenophora.** The comb jellies and sea walnuts.
Phylum **Platyhelminthes.** Flatworms, including flukes and tapeworms.
Phylum **Nemertea.** The nemertine worms.
Phylum **Nemathelminthes.** Roundworms, including horsehair worms.
Phylum **Rotifera. Rotifers** or wheel animalcules.
Phylum **Bryozoa.** The moss animals.
Phylum **Brachiopoda.** Lamp shells.
Phylum **Phoronidea.** Phoronids.
Phylum **Chaetognatha.** Arrow worms.
Phylum **Echinodermata.** Starfishes, brittle stars, sea urchins, sea cucumbers, sea-lilies, basket stars.
Phylum **Mollusca. Snails, chitons, mussels, squids, cuttlefish, nautilus.**
Phylum **Annelida.** The segmented worms.
Phylum **Arthropoda. Crustaceans, spiders, scorpions, insects,** etc.
Phylum **Chordata.** Fishes (**Pisces**), **amphibians, reptiles,** birds (**Aves**), **mammals,** and a few other forms.

Similar principles have been adopted for the classification of plants. (See **Paleobotany** and **Nomenclature.**) (A.W.L.)

CLASTIC ROCK. A sedimentary rock that is entirely or chiefly composed of fragmental material. **Sandstones** and **conglomerates** are typical clastic rocks. (R.M.F.)

CLAVICLE. The collar bone of man. The ventral anterior bone of the **pectoral girdle of vertebrates.** (A.W.L.)

CLAY. Clay is a very fine-grained unconsolidated rock material which is plastic when wet, but becomes hard and stony when heated to redness. Mineralogically, clay consists chiefly of hydrous **silicates** of **aluminum** together with numerous impurities, as **hematite, limonite,** etc., which often impart various colors to it. (E.S.C.S.)

CLAY GALLS. Thongallen.

CLAYDEN EFFECT. A photographic effect discovered by A. W. Clayden (1900). A photographic material which is first given a partial exposure to diffuse light, produces a reversed image if exposed a second time to a brilliant source of light. The effect is observed frequently in photographing lightning. If the lens is left open to await a flash in the proper position, other flashes occurring in the meantime (street lights, etc.) produce a general exposure. Then when a brilliant flash occurs the shutter is closed and the image developed. The image of the flash may develop as a positive or as a negative depending upon the relation of the two exposures. (C.B.N.)

CLEARANCE. The distance by which one object clears or misses another is called the clearance. Although this term might be applied to almost any number of situations, there are some cases of special importance.

Clearance in a piston and cylinder mechanism, such as found in the **engine**, is the space left in the end of the cylinder when the piston is in dead center position towards the end of the cylinder for which the clearance is determined. This space in volumetric units of measurement is the clearance volume. Clearance is commonly stated as a percentage, being the ratio of the clearance volume to the piston displacement during a stroke. The per cent clearance is a characteristic of no little importance to the performance of steam engines and internal combustion engines. (See **Ratio of expansion.**)

The unobstructed space which must be allotted for the occasional removal of parts of physical equipment such as the rotors of motors or turbines, the tubes of a boiler, etc., may be accurately referred to as clearance. (See **Fit; Gearing.**) (F.T.M.)

CLEAR-WINGED MOTH. Insecta, Lepidoptera. A **moth** whose wing membranes are largely free from scales and therefore transparent. A majority belong to the families Aegeriidae, containing the squash-borer and other borers of economic importance, and Sphingidae or hawk-moths, of which the genus *Hemaris* includes such species. (A.W.L.)

CLEAVAGE. In biology, cleavage is the subdivision of the fertilized **ovum** which precedes the formation of germ layers as the first stage of **embryonic** development. In the simplest type of cleavage the egg and each cell thereafter split completely through; this process is called holoblastic cleavage. With the accumulation of yolk in the egg its division is hampered until in the eggs of birds and reptiles the living matter lies on one side of the yolk and cleavage merely subdivides this small mass into a layer of cells; this is meroblastic cleavage. In still other eggs with much yolk, such as those of the insects, cleavage gives rise to a layer of cells completely enclosing the yolk. The last type is called superficial cleavage.

In geology, cleavage is the tendency of crystalline minerals to split more easily in certain definite directions, with the development of more or less smooth surfaces called cleavage planes. Cleavage planes can only be developed parallel to some possible crystal face. Cleavage may be described either in terms of the ease with which it is developed, or its direction. **Slaty cleavage,** as the term implies, is the tendency for slaty rocks to split in relatively thin, flat plates. Slaty cleavage is the result of the **metamorphism** (**foliation**) of a sedimentary rock (**shale** or mudstone) and is not to be confused with mineral cleavage. (A.W.L., R.M.F.)

CLICK BEETLE. Insecta, Coleoptera. **Beetles** with a peculiar junction between the first and second thoracic segments which permits them to be moved with a convulsive snap. When laid on its back the beetle uses this method of righting itself, throwing itself into the air by these snapping movements of the body. Most members of the family Elateridae and some of the Eucnemidae are click beetles. (A.W.L.)

CLICKS, KEY. Keying.

CLIMACTERIC. That time or portion of a person's life during which the body undergoes a radical change. The term refers particularly to puberty and the **menopause.** (R.S.M.)

CLIMATE. Average weather of any region. Averages need not be for a whole year but can be computed from data for months, weeks, or days. It is necessary that sufficient data be available to remove the element of irregularity from climatic values. (P.E.K.)

CLIMB CUTTING. There are two methods of machining surfaces with rotating multi-toothed cutters; in the first method, known as climb cutting or cutting down, the work moves or feeds in the same direction as the periphery of the cutter teeth at the line of contact; in the second, known as cutting up, the work feeds in a direction opposite to that of the periphery of the cutter teeth at the line of contact. In cutting up action, each tooth of the cutter takes a wedge-shaped chip whose initial thickness is zero and whose final thickness depends upon the rate of feed. The cutting action has a tendency to lift the work from the surface on which it is placed, and work must therefore be restrained vertically as well as longitudinally.

Climb cutting produces a chip of maximum thickness at the beginning and zero thickness at the end of the cut. As a result, the machined surface has a better finish than can be obtained by cutting up.

Climb cutting has one major disadvantage. The cutting action has a tendency to draw the work in towards the cutter. This tendency is manifested when a heavy feed is used or when the machine is not sufficiently rigid or powerful for the size of the cut. In such a case, the cutter tends to climb over the work and may thus ruin the work, the cutter, and possibly the machine. For this reason climb cutting is not employed for medium and heavy-duty service, particularly where comparatively old machine tools are used. (H.C.H.)

CLIMBING PERCH. Pisces, Teleostei. An Indian fish (**Pisces**), *Anabas scandens,* not related to the true perch, which is able to move along the ground by using its paired fins. It and allied species secure oxygen from the air by means of a special organ associated with the gills. It has been said to climb low trees but it climbs rarely, if at all. (A.W.L.)

CLINKSTONE. Phonalite.

CLINOGRAPHIC REPRESENTATION. Pictorial Representation.

CLINOMETER. A pendulum-like instrument for measuring angle of slope, usually in degrees. Used by geologists for measuring the **dip** of formations. (See **Brunton Compass.**) (R.M.F.)

CLITELLUM. A swollen glandular region occupying several segments near the anterior end of the **earthworm.** It is an accessory reproductive structure. (A.W.L.)

CLITORIS. The organ in the female corresponding to the penis in the male. It is a small cylindrical organ about an inch long, situated in the anterior angle of the **vulva,** capable of erection. Unlike the penis the clitoris is not traversed by the **urethra.** (R.S M.)

CLOACA. A chamber at the end of the gut which receives the ducts of the reproductive and excretory systems. A cloaca occurs in the **rotifers** and in many **vertebrates** but in most **mammals** it is present only during **embryonic** life. (A.W.L.)

CLOCK. Time.

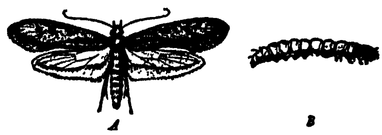
CLONE. The descendants of a single individual produced through continued asexual reproduction. As parts of the parental body, these individuals may be expected to have the same heritage. (A.W.L.)

CLOSED TRAVERSE. Traverse.

CLOT. A firm mass which results from coagulation, or change from a fluid or semi-fluid state to a semi-solid soft mass. This occurs in blood or lymph when it escapes

from the blood or lymph vessels. For a discussion of the mechanism of blood clotting, see **coagulation.** (D.M.H.)

CLOTHES MOTH. Insecta, Lepidoptera. A **moth** whose **larva** eats dead and dry animal matter, especially fur, feathers, and wool. Three species are known. The



A, clothes moth. B, larva of clothes moth. (*After Riley. U. S. Dept. Agr.*)

case-bearing clothes-moth larva, *Tinea pellionella,* lives in a case made of bits of the material on which it lives, spun together with silk. The tube-building or tapestry moth, *Trichophaga tapetiella,* makes a gallery of silk and fragments as it works. The common or naked clothes-moth larva, *Tineola biselliella,* does not spin until it makes its cocoon. The adults of all three species are small, expanding usually about ½″. As in the case of the **buffalo carpet-moth** good housekeeping is the best remedy for these pests. When present they may be killed by the use of commercial sprays or in heavy infestations by fumigation.

Frequently when moths become over abundant in a house it is due to some forgotten breeding place, such as feathers or old garments in storage. A search in unexpected places is often the best cure for such attacks. (A.W.L.)

CLOUD CHAMBER. An enclosure containing air or other gas saturated with water vapor, the cooling of which by a sudden expansion results in the formation of fog droplets upon particles of dust or other nuclei. That **ions** in the gas are capable of serving as condensation nuclei, even when no dust is present, was demonstrated by the experiments of C. T. R Wilson. Thus the clouds produced are much more dense if the gas is traversed by some ionizing emission like **x-rays** or **alpha rays.** Sir J. J. Thomson utilized this effect in his early measurements of the electronic charge. One of the most striking phenomena of the Wilson cloud chamber is exhibited when single ionizing particles, such as alpha or beta particles, are allowed to traverse it just before the expansion. The path of each particle is marked by a visible white streak or "track" of mist, sometimes several cm. in length, which soon diffuses and disappears. The study of photographs of such cloud tracks has in recent years afforded much information as to the nature and the movements of the particles producing them. (L.D.W.)

CLOUD TRACK. Cloud Chamber.

CLOUDBURST. Torrential rainfall, usually associated with thunderstorms. Very frequently an excessive number of large drops occur in a cloudburst. (P.E.K.)

CLOUDED LEOPARD. Mammalia, Carnivora. A **cat,** *Felis nebulosa,* of southeastern Asia, neither closely related to the true leopard nor like it in markings. (A.W.L.)

CLOUDS. Large numbers of water droplets or ice crystals virtually suspended in the atmosphere. Actually the water or ice in a cloud occupies only a small fraction of the total space appearing as a cloud. Light is well reflected from the droplets or crystals and the cloud body appears as an opaque drifting object. Clouds can be classified in several ways. The two most common are in regard to form, stratified or billowed; and in regard to height, high, medium, or low. The basic cloud forms are internationally recognized but there are many variations of each form.

Cirrus is a high cloud composed of ice crystals and, therefore, lies entirely above the freezing level. Cirrus is never lower than about 4 miles in the tropics but may be near ground levels in the polar areas. In appearance they are usually thin, wispy, often in streaks, and always whitish without shadows. Cirrus often forerun storms but not all cirrus are associated with storms. They cannot be used as a foolproof indication that a storm is approaching until considerable experience in cloud observation is attained.

Cirrostratus is a cloud veil of more or less uniform texture composed of ice crystals and therefore, like cirrus, lies entirely above the freezing level. Cirrostratus varies from white to gray, is usually translucent, and partially obscures the sun and moon. There are no shadows but often mock-suns or mock-moons which are images of the real celestial bodies. Cirrostratus often heralds the approach of a cyclonic storm, particularly in the temperate zone.

Cirrocumulus is a small billowed cirrus-type cloud composed of ice crystals. This type cloud indicates some instability in the layer at and above the cloud level which permits rising currents to form the cloud parcels and descending currents to create clear spaces between them. Cirrocumulus frequently occurs in advance of a cyclonic storm.

Altostratus is a translucent to opaque cloud composed of water droplets through thin layers of which the sun or moon might appear as seen on a ground-glass screen. It is a middle-level cloud in contrast to the high cirrus forms but may lie either above or below the freezing level. Very frequently, the top part of a layer of altostratus is a cirrus-type cloud, although this is not observable from below. Altostratus cast very little if any shadow but usually appear as a dull, drab, grayish sheet. Altostratus following cirrus and cirrostratus is an almost certain indication that a cyclonic disturbance is approaching.

Altocumulus is a billowed cloud of small cumuli that generally form in layers. It is composed of water droplets, although it may lie either above or below the freezing level. It is a middle-level cloud. Altocumulus casts shadows and varies in color from pure white to nearly black. In general they are whitish with darker shadows. "Mackerel sky" is an appropriate description for many altocumulus bands. The cloud may or may not be associated with cyclonic storms.

Stratus is a uniform layer of dull, grayish, low-level cloud. It is not the low-level equivalent of altostratus, rather it is more a cloudlike fog. Fragments of stratus torn by wind or remnants of clearing stratus are usually known as fractostratus.

Nimbostratus is a type of stratus from which rain or snow appears to fall. Usually the stratus layer is merged with altostratus or altocumulus, and the total cloud layer is very deep. More frequently there is a clear break between the two layers. Nimbostratus is dull and grayish and usually ragged.

Stratocumulus is a layer consisting of large lumpy masses of cloud. It is billowed, often appears in rolls with occasional blue showing between rolls. The cloud casts considerable shadow with shades varying from very whitish in thin spots to very dark in thick spots. Types vary from almost true cumulus to almost true stratus.

Cumulus clouds are billowed heaps with flat bases and tufted tops. They have considerable shadow and often are very dark on the underside. Size and shape vary from flat small balls of cloud-cotton to great towers with valleys and ravines along the sides. The cloud is a low type but can be found with bases from 500–1000′ and tops as high as 20,000′. It is composed of water droplets and may produce rain if well developed. Flat, fair-weather types are known as cumulus humilis and the well-developed variety as cumulus congestus.

Cumulonimbus is the thunderstorm cloud. It is tall, billowed, full of contrast from brilliant white to inky black. Most of the cloud is composed of water droplets but the top which penetrates above the freezing level is composed of ice crystals. False cirrus often develops at the top or anvil head. Cumulonimbus occur with bases from 500–15,000′ and tops from 10,000–50,000′.

There are also several minor cloud forms. Scud is generally wind-torn nimbrostratus. A lenticular cloud is a feather-shaped cloud usually formed over the peak of a mountain or terrain where the wind blows uphill and the air reaches the condensation level near the top of its flow. Lenticular clouds also form in mid-air if there is considerable undulation in the horizontal winds and if the air rising on the crest of a wave reaches the condensation level. Clouds of this type do not travel with the wind but remain practically stationary. Crest clouds form, covering ridges and mountain tops in a similar fashion, but are more extensive and do not usually have the lenticular form. They develop in a current of air rising along the ridge or mountain when air reaches its condensation level along the slope. Mammatocumulus sometimes are associated with severe thunderstorms. They appear as small inverted cumulus with the bulges extending downward. They are indications of extreme turbulence. Fracto clouds are wind-torn clouds. They are usually low clouds, cumulus or stratus. (P.E.K.)

CLOVER. **Pea Family.**

CLOVES. **Eugenia aromatica.** Myrtaceae. Cloves are the dried flower buds of a beautiful evergreen tree growing 25–40′ high. Its native home is the Molucca Islands. In cultivation it has spread throughout tropical Oriental islands. The trees grow best when near the coast. The clove tree has thick shining leaves, a smooth gray bark and flower buds and flowers of deep red color. The fragrant oil is located mainly in the leaves and flower buds, and causes the air surrounding the tree to be richly scented. Flower buds are first formed when the tree is 4 or 5 years old. In gathering, the branches are pulled down and the flower buds picked off by hand, or they may be pounded from the trees with bamboo sticks. After gathering, the pedicels, or short flower stems, are picked off, and the buds dried. These buds may now be used as a spice, either whole, or ground to a powder. They are also used to improve the breath; indeed, in ancient times it is recorded that their use for this purpose was required before royalty could be addressed, a commendable requirement. In addition to their use as spice, an oil is distilled off and condensed by cooling. This oil, which is rich in eugenol, is much used in making artificial vanilla. Clove oil (see **Volatile Oils**) is also used in scenting soaps and perfumes. It is also much used in the preparation of sections which are to be examined by the microscope, it being a means of clearing the sections. (R.M.W.)

CLUB FOOT (Talipes). A deformity of the foot, usually congenital in origin, characterized by marked flexion, extension, inversion, or eversion.

Heredity is a factor in some cases. In others the condition results from an intra-uterine accident or maldevelopment, firm pressure or constriction due to deficient **amniotic** fluid, or tumor in or around the **uterus**, interlocking of the feet, constriction of the umbilical cord, pressure of twins, etc.

Treatment is effective in childhood. In older children the prognosis for a useful foot is not as good. Treatment may be manipulative or operative, depending on the type of deformity and the age of the patient. (R.S.M., D.M.H.)

CLUB MOSSES. **Lycopodiales; Paleobotany.**

CLUSTERS. An examination of the night sky will indicate at once that the stars are not uniformly distributed. Certain clusters may be readily distinguished by the unaided eye, such as the **Pleiades**, the **Hyades**, the **constellation** of Coma Berenices, Praesepe, and the double cluster in **Perseus**. The application of the **telescope** to astronomy revealed a number of other clusters and the application of photography further augmented the number until at present several hundred such objects are listed. Star clusters are studied under two main types, galactic clusters and globular clusters.

A galactic cluster contains between a few hundred and a thousand stars far enough apart to be distinguished as individuals. The name galactic is derived from the fact that all except two or three of the brightest and closest of these objects lie within 15° of the **galactic** plane. The method of determination of the distances and sizes of those galactic clusters which are close enough to be classified as **moving clusters** are discussed elsewhere. For the more distant ones the **spectral classes** of individual stars are plotted as abscissae and apparent **magnitudes** as ordinates and the resulting diagram compared with that obtained for **giant and dwarf stars.** From this comparison an approximate determination of **absolute magnitudes** may be made and the distance determined. From the distance and observed angular diameter of a cluster its linear diameter may be found. By such methods a few galactic clusters are found to be within a few hundred **light years** of the sun, while the great majority are between 1500 and 15,000 light years away. The shapes of the galactic clusters are quite irregular.

The globular clusters contain thousands of stars and are characterized by their globular form and concentration of stars in their central regions. In a moderately large telescope these objects are strikingly beautiful to see. Many attempts have been made to determine the total number of stars contained within a globular cluster, but the concentration at the center is so great that the images all run together. Certainly, in the brighter objects of this class there are more than 50,000 stars. Shapley finds, from an extensive study of a number of clusters, that there are stars of all spectral types, but there is a very definite correlation between spectral class and brightness, with the fainter stars all being redder than the brighter ones.

The distances of globular clusters may be approximately determined from the cluster type **Cepheid variables** which are found in large numbers in these objects. Shapley finds that the globular clusters are all contained within a vast ellipsoid with a maximum diameter of approximately 250,000 light years, having its center about 75,000 light years from the sun in the direction of the constellation of **Sagittarius.** While the principal plane of this ellipsoid practically coincides with the **galactic plane,** nevertheless practically none of the globular clusters are observed close to the milky way. The only plausible explanation seems to be found in the hypothesis that there is some sort of absorbing material in this region of space.

A study of the shapes of the globular clusters indicates that they are somewhat ellipsoidal as though they were rotating, but no rotation has ever been definitely observed. From the estimated distances and angular diameters the diameter of the clusters is found to be of the order of magnitude of 100 light years. In the central dense portion of a globular cluster there must be about 1500 times as many giant stars as there are in an equal volume of space in the vicinity of the sun. However, even with this relatively close packing of stars, the average distance between the individuals must be of the order of magnitude of 1 light year. (W.K.G.)

CLUTCH. The function of a clutch is to effect the coupling of two working parts in such a way as to permit connection or disconnection at will, and without the necessity of bringing both parts to rest. Almost always a clutch is a coupling between two **shafts** which are in line, one being the driving, the other the driven,

shaft. Under these conditions the function of the clutch upon being engaged is to pull the driven member up to the speed of the driving member, and to transmit the required amount of power without **slip**.

Clutches may be classified according to the method of transmitting the torque:

1. Friction clutches are operated by the surface friction created when two surfaces are pressed together.
2. Magnetic clutches make use of the attraction of a magnet for its armature. This type has attractive features, but has made little headway because of the development of the friction clutch.
3. Jaw clutches are those in which positive drive is obtained by the use of projecting lugs. If this type of clutch is engaged when the drive is in motion, there will be a sudden shock to the driven mechanism unless some degree of flexibility is imposed between clutch and driven machinery by the use of springs, rubber, or the like.

Most clutches are of the friction type, since it has been possible to build this type to transmit almost any amount of power desired with moderate-sized clutches which are comparatively trouble-free. The friction clutch may be engaged either by an axial or by radial movement. Cone and disk clutches are the former type; internal-expanding shoe and external-contracting bands are examples of the latter.

The **internal combustion engine** is not easily started under load, and therefore when used to power self-propelled vehicles, it must be disengaged from the axle for starting purposes. For this reason every automobile, truck, or bus must have a clutch. The two clutch forms frequently used for this service are the cone clutch and the disk clutch.

In explanation of the cone clutch, the reader is asked to refer to Fig. 1. In this figure at A the clutch is

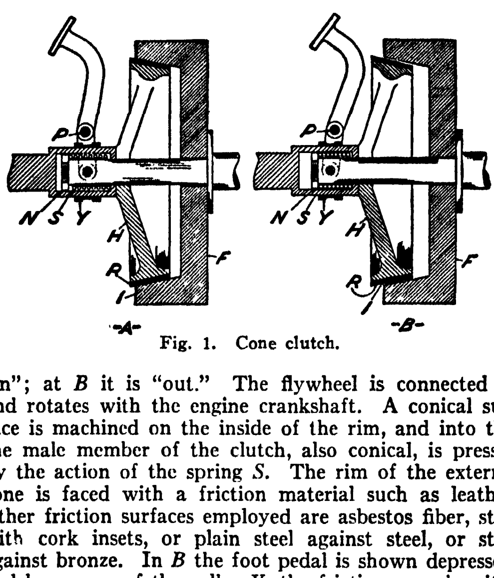


Fig. 1. Cone clutch.

"in"; at B it is "out." The flywheel is connected to and rotates with the engine crankshaft. A conical surface is machined on the inside of the rim, and into this the male member of the clutch, also conical, is pressed by the action of the spring S. The rim of the external cone is faced with a friction material such as leather. Other friction surfaces employed are asbestos fiber, steel with cork insets, or plain steel against steel, or steel against bronze. In B the foot pedal is shown depressed, and by means of the collar Y, the friction cone is withdrawn, compressing the spring S. The spring pressure required is that needed to produce the force at the friction surface which is necessary to transmit the required horsepower. If the mean diameter of the friction surface is D ft., and P hp. is to be transmitted at N rpm., then the sum of all the friction forces acting in the friction surface can be expressed by the following formula:

$$F = \frac{33{,}000P}{2\pi N \times \frac{D}{2}} = \frac{33{,}000P}{\pi ND}.$$

The fundamental law of friction states that frictional force equals coefficient of friction times pressure normal to the surface, hence, calling the pressure normal to the surface Q,

$$Q = \frac{F}{f},$$

in which f is the coefficient of friction of the contacting surfaces.

The conical clutch surface is used because a small spring pressure acting along the axis of the shaft will produce a large force if the cone angle is small. If the central angle of the cone is α and the force exerted axially by the spring is S,

$$Q = \frac{S}{\sin \alpha}.$$

The cone clutch is either metal to metal, running in an oil bath, or leather to metal, running dry. Since the leather must be kept soft and pliable, but free from grease, necessitating a certain amount of inspection and maintenance, this type of clutch has been superseded, for automotive uses at least, by the disk clutch. The dry-plate disk clutch operates without lubrication, gaining thereby so high a coefficient of friction that one plate held between two disks usually will develop sufficient friction force. Fig. 2 shows a multiple disk clutch of

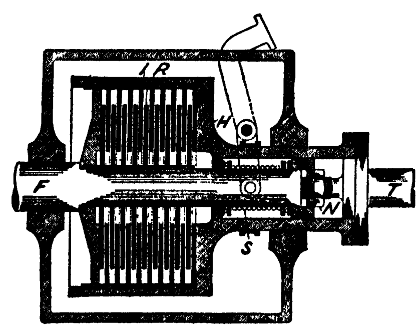

Fig. 2. Multiple disk clutch.

the type frequently used in the automobile. F is an extension of the crankshaft to the engine, and carries with it the series of disks similar to R. The driven shaft, T, is expanded inside the clutch to a large diameter drum having mounted internally a series of disks similar to I, alternating with the R disks. In each case the disks must move with their respective shafts, but are permitted some endwise movement through the method of attachment. The clutch is shown in disengaged position. Should the clutch pedal be released, the spring S will push on the member H and press together the fixed and moving disks. The friction set up thereby will pull the driven shaft up to speed, and then transmit to it the power for which the clutch is designed. Such clutches are sometimes metal to metal, immersed in oil, or metal to friction material if run dry. (F.T.M.)

CNIDOBLAST. A stinging cell of the **coelenterates**, found in all forms, **polyps**, **jellyfishes**, and **sea anemones**. It produces **nematocysts** which are discharged in defense and in securing food. (A.W.L.)

CNIDOCIL. A projection on the free surface of a **cnidoblast** which is sensitive to external stimuli. (A.W.L.)

COAGULATION. 1. The clotting of **blood** or **lymph**. 2. The changes produced in tissue by the application of increased temperatures or by certain chemicals.

The mechanism of the clotting of blood is not completely understood. It is now generally believed that two reactions occur as part of the process, both of them involving **enzyme** systems. The substances concerned in the formation of fibrin and therefore clotting are certain blood **proteins** (**fibrinogen**, **prothrombin**, **thrombin**)

and thromboplastin, or tissue factor, which is widely distributed as an intracellular substance and is liberated when the blood platelets (see **Blood**) or other cells are injured. **Calcium** also takes part in blood clotting. All these substances are postulated to interact in the following manner:

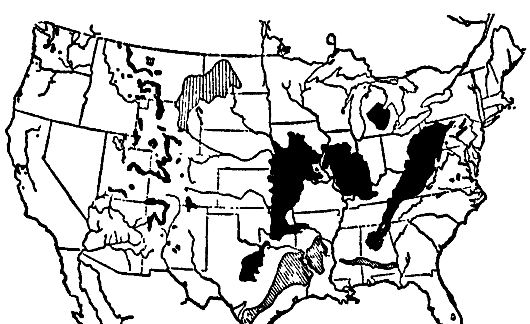
1. Thromboplastin + calcium ions, react with prothrombin to produce thrombin.
2. Fibrinogen + thrombin produces fibrin, which forms the clot.

Failure of the clotting mechanism anywhere along the line, results in various blood diseases, such as **hemophilia, purpura hemorrhagica,** etc. Vitamin K is necessary for prothrombin formation, and its deficiency results in a bleeding tendency. (See **Vitamins.**) (D.M.H.)

COAITA. Mammalia, Primates. The red-faced spider-monkey of the Lower Amazon. (A.W.L.)

COAL. A combustible substance of organic origin which occurs as beds or "seams" and which has a variable physical and chemical composition, including variable amounts of mineral or non-combustible matter. Although the combustible constituents of coal are of organic origin, the geological processes involved in its formation act so slowly and over such a long period of time that coal is, economically speaking, non-reproductible.

It is known that the origin of coal is to be sought in the vast and luxuriant vegetation which flourished over portions of the earth's surface in past geological ages, for the imprint of leaves of giant tree ferns of a form similar to those now found only in tropical jungles can often be seen on the face of blocks of coal at the mine. (See **Paleobotany.**) Undoubtedly the somewhat higher mean temperature of the earth, coupled with the prevalence of a more steamy atmosphere, produced conditions which led to very rapid growth of vegetation. Such conditions are today approximated in hothouses, so it is probable that the coal-forming epochs are definitely of the past, and that such coals as are used constitute a depletion of a fixed natural resource. Through the centuries of the **carboniferous** age there was produced a rapidly accumulating mass of decaying vegetation, a great deal of which was undoubtedly also preserved from complete decay by having air excluded from it either by its being partially submerged or being covered with a considerable thickness of superimposed matter. The process of decay soon converted the **cellulose, lignin,** and **proteins** of the original vegetable debris into peat bogs which, due to some subsequent earth movements, were either rapidly or gradually covered with inorganic material which, in time, produced sedimentary rocks such as shale or sandstone. Coal is found today in bedded deposits, or seams, in company with **shale, sandstone, limestone,** and other sedimentary products. The pressure of the overlying strata, together with some possible small amount of residual decay, created an increase of temperature in the peat which slowly accomplished its conversion into coal. The fact that under conditions of controlled pressure and temperature a material of vegetable origin may today in the laboratory be converted into a black powder resembling coal, lends credence to this theory of the origin of coal. It is entirely conceivable that the variations in overlying strata, in condition of the bed when overlaid, and in subsequent rise of temperature, are accountable for the differences in coal as it is brought from the mines today. During the process of this chemical change, percolation of water through the incipient coal seams probably carried into the coal many of the minerals which, in the aggregate, produce the ash which is common to all coals. (Of course, some of the ash can be attributed to the minerals present in the vegetation from which the coal was formed.) The classification of coal is primarily in terms of its origin both as to (1) composition, or the original types of vegetable material composing it, and (2) the degree of **metamorphism** which it has undergone since burial. A simple but practical classification of coal according to its origin and chemical composition is as follows: (1) Peat. Partially carbonized vegetable matter, such as accumulates in a bog. Because of its high water content, peat is not an economical fuel when either lignite or coal is available. (2) Lignite. Brown coal and lignite are formed by the burial and consequent compression of peat by overlying sediments (formations), the peat substances being thus compacted and changed, first to brown coal or **lignite,** and then to black lignite or sub-bituminous coal. Although lignites are thus the parent forms of the higher grades of coals, even pure lignite is a relatively poor form of fuel because of its high water content and consequent low calorific value. Calculated on an ash-free basis, lignite yields moisture, 43.4%; volatile matter, 18.8%; fixed carbon, 37.8%; heat value in **British Thermal Units,** 7400 B T.U. per lb. (3) Bituminous Coal. Soft Coal (bituminous) varies in heating value from 9720 to 15,360 B.T.U. per lb. The various ranks of bituminous contain roughly 70–80% of fixed carbon and 30–20% of volatile matter. When most bituminous coals are heated in a closed retort this volatile matter is driven off as gas and **coal tar.** The residue of fixed carbon may form a coherent porous mass called **coke.** Coking coals are particularly valuable as they yield the essential fuel for the smelting of iron ores. Other by-products of bituminous coals are a great series of organic compounds which are used extensively in the dye and other industries. (4) **Anthracite** (Hard Coal). When bituminous coals have been heated and compressed (by natural geological causes) so that they have changed from the finely jointed and crumbly "Soft Coals" to the massive and hard form, they are called anthracite, which is relatively hard, clean and moisture free; low in volatile matter and high in fixed carbon. Anthracite grades (through **metamorphism**) to **graphite** which is high in fixed carbon, combustible only at high temperatures, and classed as a refractory. High-grade anthracite, calculated on the ash-free basis, yields moisture, 3.2%; volatile matter, 1 2%; fixed carbon, 95.6%; and heat value, 14.400 B.T.U. per lb. The geologic distribution of coal is as follows: Pre-Paleozoic. No coal beds but abundance of graphite in the **Archeozoic** crystalline rocks. **Paleozoic.** Important bituminous and anthracite coal deposits in England and eastern United States of **Pennsylvanian Period.** (See **Historical Geology.**) **Mesozoic.** A few beds of **cannel** and bituminous coals occur in the **Triassic.** In the **Cretaceous** occur a great series of bituminous coal beds second only in importance to those of Pennsylvanian age in the eastern United States.



Map of the United States showing the principal coal fields. The lined areas represent lignitic coals. All solid black areas east of the Rocky Mountains, excepting the very small ones of Triassic age in Virginia and North Carolina, represent fields of Pennsylvania coal. All coal in the western United States is Cretaceous and Tertiary. (*Modified after U. S. Geological Survey.*)

Cenozoic. Poor grades of lignite and bituminous coals occur in the **Tertiary.** These coals are of some value for local use only. The chief coal reserves of the world

are located in the United States, England and the territory contiguous to Germany and France.

Coal contains **carbon, hydrogen, oxygen, nitrogen, sulfur,** and various mineral substances such as **silica, alumina,** and iron (ferric) oxide. All of the mineral substances are included in the descriptive term ash. Hydrogen is present in coal in two forms, called *free* and *combined,* although actually it is in two methods of combination. Hydrogen is combined with oxygen, forming the moisture in coal, and all coal contains more or less moisture. Hydrogen is also combined with carbon, forming the hydrocarbon, or volatile portion of coal. A very important difference, however, exists in these two combinations of hydrogen. In one, water, it is completely oxidized, and must be considered incombustible; in the other, the hydrocarbons, the hydrogen is combustible. Occurrence of ash in coal is more or less accidental. Coal rarely contains more than 4% of sulfur, or 2% of nitrogen. Only a small portion of the carbon content of coal is accounted for in the volatile portion (the hydrocarbons); in fact, the largest portion of the heating value of coal is obtained from the free or "fixed" carbon. A sample analysis of anthracite coal is: 2% moisture, 5½% volatile material, 86½% fixed carbon, 6% ash. Typical semi-bituminous coal, the principal steaming coal, would be covered by the following analysis: 3% moisture, 18% volatile material, 75% fixed carbon, 4% ash.

The analysis of coal on the basis just described is known as the **proximate analysis,** but studies in combustion, which is essentially a chemical reaction, necessitate analyzing the coal into its elements. This analysis is known as the **ultimate analysis.** Since the heating value of hydrogen is roughly five times that of carbon, it follows that the coal high in volatile material possesses a higher calorific value.

The combustion of free carbon liberates 14,500 B.T.U. per lb., of free hydrogen 62,000 B.T.U. per lb., and of sulfur 4000 B.T.U. per lb. One pound of coal has theoretical heating value of

$$HV = \frac{14{,}540C + 62{,}000H + 4000S}{100} \text{ (B.T.U.)}$$

C = the per cent of carbon in the coal. S = per cent of sulfur in the coal. H = per cent "free" hydrogen in the coal, understood to be that portion of the total hydrogen in an ultimate analysis which is not already combined with oxygen. The actual heating value of coal as determined by calorimeter may be slightly different from that yielded by the above formula, because of exothermic or endothermic reactions that take place during combustion such as the heat of decomposition of hydrocarbons, etc. Since, for coal, the endothermic or heat-absorbing reactions are usually of greater magnitude than the exothermic, the actual heating value is less than that determined by the formula.

The commercial production of coal is a vast and highly intricate business. In recent years it has suffered from the considerable competition of oil and natural gas, and, in general, the industry has suffered from intensive competition. The seams which are worked are usually less than 10′ thick, and are generally overlaid with a rock cap which is shored up as the coal is removed. Some coal is mined by the open or strip method, in which the overlying earth is stripped off by power shovel. Coal is undercut or blasted out of the face of a seam and loaded onto cars which convey it to the plant, where the slate is removed before the coal is broken and graded.

Bituminous coals are produced in the following sizes:

Run of Mine. This coal is mined, unscreened, and varying in size from large lumps to slack.

Lump. Coal which passes over a 1¼″ screen.

Nut. Cut coal of a size which passes through a 1¼″ screen, but is retained on a ¾″ screen.

Slack. All coal passing the ¾″ screen.

Anthracite coal, in addition, is produced in the finely graded sizes called Pea and Buckwheat.

The firing qualities are important characteristics of coals when selection of coal or coal-burning equipment is under consideration, for, if it were not for the effects of firing qualities and impurities, coal could be purchased on the basis of heating value alone. The firing characteristics of coal result from (1) its volatile content, (2) moisture content, (3) sulfur content, (4) ash composition. Some coals retain their original shape during combustion, being gradually reduced in size as combustion proceeds; others soften and fuse into a mat or crust which blankets off the air supply; others soften but do not form a crust. This quality influences the stoker selection. The sulfur and ash content will have much to do with the types of clinkers that are formed. The fusion temperature of the ash becomes an important characteristic when low excess air and high furnace temperatures are employed. The hardness and way in which a coal shatters when pulverized may influence the selection of pulverized fuel equipment. Some coals are fast-burning, others slow. That characteristic influences shape and thickness of fuel bed carried, or type of burner installed. The tendency of a coal to disintegrate and become slack will affect the type of grates and the draft used.

The bulk of coal is transported by boat or railroad, although these are supplemented, to a limited extent, by trucks and wagons. The individual user of coal usually puts considerable quantities of it in storage as insurance against complete shut-down of a plant occurring from failure of normal fuel supplies to arrive. When coal is piled in storage it "weathers." It has a tendency to become slack; the surface oxidizes and heat is liberated. When loosely piled in shallow piles or large lumps, natural circulation of air currents carries the heat away rapidly enough so that the temperature does not rise dangerously. Fines with their larger surface exposure must be watched more carefully than coarse lumps. Two methods of preventing spontaneous combustion are practiced. One of them is to promote sufficient circulation of air to carry off heat at low temperatures. This is done by shallow piling and by use of ventilating ducts. The other is to store in such a way that the oxidizing air is excluded from the coal.

Coal is the source of a great many important and useful by-products which are derived either from distillation or carbonization of bituminous coal. Amongst the more important of these might be mentioned the following: illuminating and fuel gas, coke, ammonia, analine and other dyestuffs, explosives, pitch, cresoline and paint compounds, antiseptics, tar. (R.M.F., F.T.M.)

COAL BALLS. Concretions composed of mineralized plant fragments preserved as **petrifactions.** Because the original structure of the plants has been so well preserved, the coal-ball flora has been of great aid to **paleobotanists** in determining the character of the **carboniferous** flora. (R.M.F.)

COAL MEASURES. Upper Carboniferous.

COAL TAR PRODUCTS AND INTERMEDIATES. When coal tar (see **Destructive Distillation, Coal**) is subjected to distillation, the various condensates contain substances of value for intermediates, which with the light oil recovered from coal gas, may be considered the immediate raw materials for making dyestuffs. While the exact treatment may vary with each coal tar obtained, general results are probably satisfactorily summarized as follows:

Fraction Collected	Name of Fraction	Percentage of Coal Tar
Up to 170° C.	Light oil	0.2
170–230° C.	Carbolic oil ⅓ phenol ⅔ cresylic acid	10
230–270° C.	Creosote oil	10
270–350° C.	Anthracene oil	25
Residue at 350° C.	Pitch	55
Residue at 1200° C.	Retort carbon	17

The light oil fraction plus light oil recovered from coal gas (the latter the main source of **benzene** and **toluene**) contains:

Fraction of Light Oil	Fraction Collected	Distillation Characteristics
Crude benzene	Up to 95° C.	90% recovered at 100° C.
Crude toluene	95–125° C.	5% " " 100° C. 90% " " 120° C.
Crude solvent naphtha	125–170° C.	5% " " 130° C. 90% " " 160° C.
Heavy naphtha	170–200° C.	5% " " 160° C. 90% " " 200° C.

Residue: Wash oil (for benzene absorption from coal gas), naphthalene and phenols. Drawn off and cooled, whereupon naphthalene crystallizes and is separated by filtration.

When these fractions are further fractionally distilled, pure benzene, pure toluene, xylenes and solvent naphtha are recovered. (See also **Hydrocarbons.**)

Benzene, toluene, xylene, naphthalene, anthracene, are the important hydrocarbons used for intermediates.

In addition to phenol there are used as intermediates the following **phenols**: cresols, resorcinol, alpha- and beta-naphthol. In addition to aniline, the following amines: ortho- and paratoluidine, dimethyl aniline, diethylaniline, diphenylaniline, benzidine, toluidine, alpha- and beta-naphthylamine, acetanilide; in addition to chlorobenzene: para-dichlorobenzene, benzyl chloride; in addition to **benzoic acid**: **phthalic acid**, phthalic anhydride, dibutylphthalate, **salicylic acid**, cresylic acid (see **Acids, Carboxylic**); also diphenylguanidine, orthoditolylguanidine (see **Guanidine**), phenylglycine, phenylglycocoll, $C_6H_5NHCH_2COOH$. (See **Aminoacids**, tricresylphosphate, benzaldehyde.)

There are about five largely used processes for producing intermediates. The products may be classified as:

1. *Sulfonated Products.* Wherein sulfuric acid concentrated is used to produce sulfonic acid products (group $—SO_3H$) by elimination of water (—OH from sulfuric acid plus H— from the benzenoid compound taken react to form H_2O). Sulfanilic acid (1-amino-4-benzene sulfonic acid) naphthionic acid (1-amino-4-naphthalene sulfonic acid and others). (See **Thio-alcohols.**)

2. *Nitrated Products.* Wherein nitric acid concentrated (usually with sulfuric acid concentrated) is used to produce nitro-compounds (group $—NO_2$) by elimination of water (—OH from nitric acid plus H— from the benzenoid compound taken react to form H_2O). (See **Nitrocompounds** (nitrobenzene, 2- and 4-nitrotoluene, meta-dinitrobenzene, 2,4-dinitrochlorobenzene, 2,4-dinitrochlorotoluene, 2,4-dinitrophenol, nitroanilines); **Nitrobenzene; Toluene; Phenol.**)

3. *Chlorinated Products.* Wherein chlorine is used to produce chloro-compounds by elimination of hydrogen chloride (—Cl from chlorine plus H— from the compound taken react to form HCl). (See **Chlorine,** organic compounds.)

4. *Hydroxylated Products.* (See **Phenols.**)

5. *Aminated Products.* (See **Amines; Aniline.**) (R.K.S.)

COATI. Mammalia, Carnivora. *Nasua.* Animals related to the raccoons but with a long snout. They occur in Mexico, Central America, and South America. (A.W.L.)

COAXIAL LINE. This is a type of transmission **line** in which one conductor completely surrounds the other, the two being coaxial and separated by a continuous solid dielectric or by dielectric spacers with gas as the principal insulating material. Such a line is characterized by no external **field** and by having no susceptibility to external fields from other sources. It is extensively used for radio-frequency transmission lines and is being installed as a multi-channel telephone **carrier** and television program line. (L.R.Q.)

COBALT. Symbol: Co. Atomic number: 27. Atomic Weight: 58.94. Density: 8.9. Melting point: 1480° C. Boiling point: 2900° C. (**Isotopes:** page 290.)

Cobalt is a silver-white metal, harder and stronger than iron or nickel, not very malleable but a small amount of carbon markedly increases the malleability and ductility, magnetic below 1150° C., soluble in nitric acid. Compact cobalt is not oxidized on exposure to air at ordinary temperature, and does not react with alkalis. Discovered by Brandt in 1735.

Cobalt occurs as arsenide and sulfide (**smaltite,** $CoAs_2$; **cobaltite,** CoAsS), generally associated with iron, nickel, copper and silver minerals, the principal sources being Ontario and Belgian Congo. The ore is treated in a **blast furnace** and recovered as arsenide of the above-contained metals, which product is roasted with sodium chloride or treated with sulfuric acid; cobaltic hydroxide is obtained by a succession of treatments and then ignited to tricobalt tetroxide. From the oxide cobalt metal is obtained by heating with carbon

Cobalt is used in alloys, (1) ferro-cobalt (35% Co) as a permanently magnetized steel, (2) "carboloy," tungsten carbide and cobalt, of high hardness and used as in cutting steel, (3) "stellite," cobalt-chromium alloy used in high-speed cutting steels, and in heat-resistant jet engine turbines.

Acetate: Cobalt acetate, cobaltous acetate ($Co(C_2H_3O_2)_2 \cdot 4H_2O$), red-violet solid, soluble, used as a dryer for paint and varnish oils.

Chloride: Cobalt chloride, cobaltous chloride ($CoCl_2$), red crystals, soluble.

Cobaltinitrites: Sodium cobaltinitrite ($Na_3Co(NO_2)_6$) soluble, and potassium cobaltinitrite, "cobalt yellow" ($K_3Co(NO_2)_6$), insoluble, are yellow solids, the latter used as a pigment.

Hydroxides: Cobalt hydroxide, cobaltous hydroxide ($Co(OH)_2$), rose-red precipitate by reaction of boiling cobalt salt solution and **sodium** hydroxide solution; cobaltic hydroxide ($Co(OH)_3$), brownish-black precipitate by reaction of cobalt salt solution and sodium hypochlorite solution.

Nitrate: Cobalt nitrate, cobaltous nitrate ($Co(NO_3)_2 \cdot 6H_2O$), red crystals, soluble.

Oxides: Cobalt monoxide, cobaltous oxide (CoO), gray to greenish solid, formed by heating cobaltous hydroxide or carbonate; used in the production of various colors with other oxides in **ceramics** such as blue, purple, green, red, yellow; cobalt sesquioxide, cobaltic oxide (Co_2O_3), black solid, formed by heating cobaltous nitrate at 180° C.; tricobalt tetroxide, cobalto-cobaltic oxide (Co_3O_4), black solid, formed by heating in air to a red heat any of the other oxides or compounds which yield these oxides by heating.

Sulfate: Cobalt sulfate, cobaltous sulfate ($CoSO_4 \cdot H_2O$), red crystals, soluble.

Sulfide: Cobalt sulfide, cobaltous sulfide (CoS), black precipitate, formed by reaction of cobalt salt solution with **ammonium** sulfide solution, relatively insoluble (after precipitation) in **hydrochloric acid.**

Cobalt soluble salts are pink, in solid or solution, but when heated gently to dehydration the hydrated salts,

preferably chloride, turn blue, and the blue turns pink upon absorption of water vapor from the atmosphere. (R.K.S.)

COBALTITE. The mineral cobaltite is a sulfarsenide (see **Sulfur** and **Arsenic**) of **cobalt,** corresponds to the formula CoAsS, crystallizing in the isometric system as cubes or pyritohedrons, also may be massive. Cobaltite has a very good cleavage parallel to the cube faces; uneven fracture; brittle; hardness, 5.5; specific gravity, 6–6.4; metallic luster; color, silvery-white to reddish, sometimes steel gray or violet to grayish-black; streak, grayish-black. Cobaltite is found with cobalt and **nickel** minerals deposited commonly by metasomatic processes. It is found in Sweden, Norway, England and the Province of Ontario. It is an ore of cobalt. (E.S.C.S.)

COBEGO. Dermoptera.

COBIA. Pisces, Teleostei. A fish (**Pisces**) of the family Elacatidae, especially the species *Elacate canada.* This species is taken on the Atlantic Coast of North America. Also called the crab-eater and the sergeant-fish. (A.W.L.)

COBRA. Reptilia, Sauria. Poisonous **snakes** of several species found in Africa and southern Asia. Distinguished by the ability to inflate the neck when aroused. The common cobra of India, *Naja naja,* is the best-known species. It attains a length of 6′, half the size of the giant cobra or hamadryad, *Naja hannah,* which is less common. The asp or Egyptian cobra, *Naja haje,* occurs in Africa.

As is true of other poisonous snakes, the effect of the bite of a cobra depends on its own supply of venom, on the location of the bite, on the condition of the victim when bitten, and on his tolerance for poison. If the fangs penetrate well, however, and the snake has a good supply of venom, the bite of any of these species is said to be almost certainly fatal. The venom acts upon the nervous system. (A.W.L.)

COCA. *Erythroxylon Coca.* Erythroxylaceae. Coca is a drug which is found in leaves of a shrub, *Erythroxylon coca,* growing wild in Peru. This shrub grows about 6′ high, and has small ovoid leaves which are whitish on the under side, small yellow flowers growing in the axils of the leaves, and scarlet fruit. Cultivation has been carried on in Peru and adjacent regions since prehistoric days. The trees have been introduced into Java where they are now extensively cultivated. The leaves of the plant are highly prized by the native South American Indian for chewing. For this purpose they are mixed with lime, or ashes, and when chewed in this form enable the masticator to endure hunger and fatigue. The active principle is a poisonous alkaloid, **cocaine,** which is extracted from the leaves. (R.M.W.)

COCAINE. One of the alkaloids obtained from **coca** leaves. It is a valuable local anaesthetic when applied to skin or **mucous-membrane** surfaces, or infiltrated into tissues. This is the basis of its medical use. Other effects include stimulation of the central nervous system, increasing the heart rate, increasing the blood pressure, and increasing the body temperature.

The disadvantage of cocaine is that because of its central nervous system effects, it is habit-forming. Addiction usually occurs only in individuals who are psychopathic personalities. The drug is taken as snuff ("snow"), by application to the gums, by mouth, or by hypodermic injection. A feeling of **euphoria,** great mental and physical strength ensues. Often **hallucinations** and ideas of persecution make the addict dangerous; an innocent person may be killed because of his delusions.

Many synthetic local anaesthetics have been developed. These have largely replaced cocaine because of their greater potency and diminished toxicity. The commonly used ones are procaine ("novacaine"), butyn, nupercaine, and metycaine. (D.M.H.)

COCCIDIA. An order of parasitic **Protozoa.** (See **Sporozoa.**) (A.W.L.)

COCCIDIOIDOMYCOSIS (Coccidiodal granuloma. Valley Fever). A fungus infection due to *Coccidiodes immitis.* The disease is prevalent in southern California and the Southwest and appears to be spreading eastward. It is contracted usually by the inhalation of **spores,** although the agent may be introduced through an abrasion in the skin. The primary infection is often so mild that it passes unnoticed; if it is associated with signs and symptoms, the picture is one of an atypical broncho-pneumonia (see **Pneumonia**) which heals completely in a few weeks. The granulomatous form of the disease, with widespread involvement of bones, joints, skin, subcutaneous tissues, and internal organs may rarely follow the acute primary infection, or it may develop years later. It is always fatal, whereas the primary pneumonic form has an excellent prognosis. There is no specific treatment. (D.M.H.)

COCCIDIOMORPHA. An order of parasitic Protozoa in some classifications, including **Coccidia** and **Haemosporidia.** (See **Sporozoa.**) (A.W.L.)

COCCOLITH. A microscopic calcareous unicellular marine plant. An important constituent of **chalk.** (R.M.F.)

COCCOSTEUS. Fossil Fish.

COCCUS. One of a family of the order of Eubacteriales which includes bacteria whose cells are spherical in form. (See **Streptococcus, Staphylococcus.**) (D.M.H.)

COCCYX. The lower end of the spinal column. It is composed of four rudimentary small vertebrae which are usually fused together. (R.S.M., D.M.H.)

COCHLEA. The auditory portion of the inner **ear of vertebrates.** (A.W.L.)

COCK OF THE ROCK. Aves, Passeriformes. *Rupicola.* Birds (**Aves**) of several species found in tropical South America. The males are crested and brilliantly colored. (See **Chatterers.**) (A.W.L.)

COCKATIEL. Aves, Psittaciformes. A small Australian **parrot** related to the cockatoos. (A.W.L.)

COCKATOO. Aves, Psittaciformes. Any member of a family of crested **parrots** whose beaks are transversely ridged on the under surface of the hook. The tail is short and broad. Cockatoos occur in the Australian and Oriental regions. (A.W.L.)

COCKCHAFER. Insecta, Coleoptera. A European **beetle,** *Melolontha vulgaris,* related to the May beetles of North America. (A.W.L.)

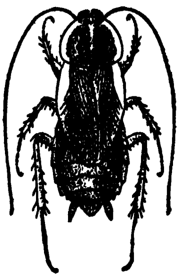
COCKLE. Mollusca, Pelecypoda. *Cardium.* Marine **bivalve** mollusks of several species. (A.W.L.)

COCKPIT. An open space in an airplane for the accommodation of pilots or passengers. When enclosed completely, such a space usually is called a cabin (F.T.M.)

COCKROACH. Insecta, Orthoptera. Flattened oval **insects,** usually brown in color. The head is almost

concealed by the broad margins of the **thorax** and in winged species the wings overlap above the body.

Cockroaches are widely known from a few species which inhabit houses, especially where quantities of food are available. They eat almost anything used by man as food and often damage other things, such as articles made of cloth containing sizing or paste. They are especially troublesome in restaurants. The two most important pests are the Croton-bug, *Blatella germanica,* and the Oriental cockroach, *Blatta orientalis.* They can be destroyed by sprinkling borax (see **Boron**), **sulfur**, or **pyrethrum** powder liberally about their hiding places or by the use of commercial roach pastes.



Cockroach.

The cockroaches gain their greatest development in the tropics, where species with a normal length of more than two inches are found. (A.W.L.)

COCOA. Theobroma Cacao.

COCOA BUTTER. Theobroma Cacao.

COCONUT. *Cocos nucifera.* Palmaceae. To the natives of tropical islands the coconut is a most valuable tree; it provides him with shelter, with dishes, with food and drink. To the inhabitant of north temperate regions, the plant is equally valuable—some half million tons of coconut oil are used annually.

The coconut tree is a striking plant having a columnar trunk 60–80′ high, bearing at its top a crown of bright green pinnate leaves, each leaf varying from 15–20′ long. The fruit is a large nut composed of three united **carpels.** The shell of the coconut has three distinct layers; the outer or epicarp is thin, smooth and brown; the middle, or mesocarp, is thick and fibrous; it is the source of the fiber, **coir.** Usually these two layers are removed before the coconuts are shipped, but not infrequently the entire fruit is exhibited as a curiosity by dealers in fruits. Within is the hard brown shell or **endocarp.** This contains the seed, which consists of an **embryo,** located under one of the germ pores at the end of the endocarp, and the **endosperm,** which is of two parts, one the familiar white meat of the coconut, the other the milk which partially fills the cavity of the seed. It is within the meat that the embryo is embedded. The thin brown skin immediately investing the meat and sticking to it when it is removed from the shell is the inner seed-coat. The hard shell of the coconut is much used as a dipper or as a vessel for storage of various substances.

The leaves of the tree yield a fibrous material used by the native islanders, and are also used at times as a thatch for shelters. The trunk of the tree is sometimes used by cabinet makers for ornamental work.

Commercially the most valuable product of the coconut is copra, the dried meat of the nut. This is obtained by splitting the nut and drying the meat, preferably by the sun. Artificial drying is done in regions of great humidity. From the meat is obtained coconut oil, which forms about 63% of the meat. The natives obtain this oil by various means. The hot sun of the tropics may cause it to dry out of the pounded meat. Crude presses are often used to squeeze the oil from the dried meats. Or again the crushed dried meats may be placed in hot water, the melted oil rising to the top and being skimmed off. Any one of these methods is sufficient to supply the moderate needs of the natives, but utterly inadequate to meet the requirements of the civilized nations.

For modern treatment, copra is shipped to large factories. Here it is cleaned and ground, then heated and pressed. The meal is then ground up once more, cooked in water and pressed by powerful hydraulic presses. By this method nearly all the oil contained in the copra is extracted.

The principal use of the oil is in the making of **soap,** especially in soaps which will produce a copious lather. Considerable quantities are also used in making butter and lard substitutes. Some oil finds use in salad oils and in confectionery. (See **Esters.**)

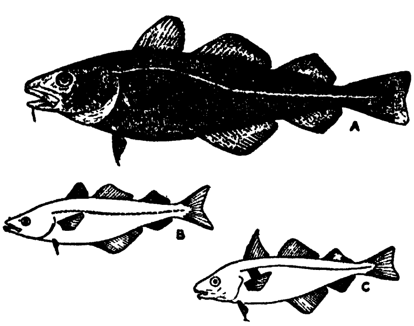
The copra cake remaining after the oil is expressed may be used as a stock feed.

Many coconuts are used to make shredded coconut, while some 20,000,000 are sold fresh each year in the United States. Another product is **coir.** (R.M.W., B.S.M.)

COCOON. A case containing eggs or young, or a developing animal in an inert stage. In the **earthworms** a cocoon to contain the eggs is secreted by a special region of the body, the clitellum, as an external structure, but most cocoons are spun of silk, like those formed by the spiders to contain their eggs and those which some **larval** insects spin about themselves when they are ready for their final transformation. (A.W.L.)

CODEINE. An **alkaloid,** one of the most valuable and frequently used **drugs.** It is one of the components of **opium** (the dried opium contains 0.5 to 1% of codeine). It is a much weaker narcotic than **morphine** and it has less power to produce sleep, or to allay pain. However, its use does not readily cause addiction. It is a component of nearly all good cough remedies because of its ability to diminish cough and allay discomfort. It is also very often used to control mild pain, and promote sleep, especially in combination with other sedatives. In chronic conditions codeine is much preferred to morphine, due to the ease of addiction to the latter. (R.S.M.)

CODFISH. Pisces, Teleostei. Fishes (**Pisces**) of a large number of species, chiefly marine. They occur in the northern hemisphere and are the most important of all food fishes.



A, cod. (*U.S.B.F. Manual.*) B, pollock. C, haddock. (*Nichols and Breder, N. Y. Zool. Soc.*)

In the cod family (Gadidae) are included the **hakes, haddocks, whiting, pollacks,** and coal fish, and in the fresh waters of northern North America a single species, the ling, **burbot,** or lawyer, is found.

The common cod, *Gadus morrhua,* has been ranked as the most important food fish. The annual catch amounts to more than one billion pounds. It is abundant in the North Atlantic. (A.W.L.)

CODLING MOTH. Insecta, Lepidoptera. The moth, *Cydia pomonella,* whose **larva** lives in apples. An important economic species.

This insect is so serious an enemy of the apple that the successful production of the fruit depends on a program of spraying which has been carefully worked out for all parts of the country. **Lead** arsenate is an effective poison but its application must be regulated

according to the entrance of the caterpillars into the fruit. Once they have penetrated the surface they are beyond reach of sprays. The principle of spraying is to apply a first spray when the petals of the flowers fall, and a second when the eggs of the next generation of insects are hatching later in the summer. Economic entomologists of the various states are prepared to furnish the proper information for various localities, according to the conditions of the year. (A.W.L.)

CODLIVER OIL. **Esters.**

COEFFICIENT OF ALIENATION. The coefficient of alienation is $\sqrt{1 - r^2_{xy}}$, where r^2_{xy} is the **coefficient of correlation** between x and y. (L.A.A.)

COEFFICIENT OF ASSOCIATION. The coefficient of association, Q, is defined by

$$Q = \frac{ad - bc}{ad + bc}$$

where a, b, c, d are the frequencies in a 2×2 contingency table as illustrated. Its use is not recommended.

a	b
c	d

Two by two contingency table.

(L.A.A.)

COEFFICIENT OF CONTRACTION. **Orifice.**

COEFFICIENT OF CORRELATION. The coefficient of correlation, r_{xy}, is defined by

$$r_{xy} = \frac{\Sigma d_x d_y}{N\sigma_x\sigma_y}, \quad d_x = x - \bar{X}, \quad d_y = y - \bar{Y},$$

σ_x is the **standard deviation** of x, σ_y is the standard deviation of y and N is the number of paired **variates** (x_1, y_1), (x_2, y_2), $(x_3, y_3) \cdots (x_N, y_N)$, $\bar{X}$ = **mean** of the x's, $\bar{Y}$ = mean of the y's. It measures the dependence of x on y or y on x when the **regression** is linear. The coefficient of correlation lies between -1 and 1. If $r_{xy} = 0$, this does not necessarily imply that the two **variables** are independent. There may be strong dependence when $r = 0$ since the **correlation** may be non-linear instead of linear. For computational purposes in a **serial distribution** the following formula is more convenient

$$r_{xy} = \frac{N\Sigma d'_x d'_y - \Sigma d'_x \Sigma d'_y}{\sqrt{[N\Sigma d'^2_x - (\Sigma d'_x)^2][N\Sigma d'^2_y - (\Sigma d'_y)^2]}}$$

where $d'_x = x - a$, and $d'_y = y - b$. The regression line of y on x is determined by

$$y' = r\frac{\sigma_y}{\sigma_x}(x - \bar{X}) + \bar{Y}$$

and of x on y by

$$x' = r\frac{\sigma_x}{\sigma_y}(y - \bar{Y}) + \bar{X}.$$

The **standard error of estimate** $\sigma_e = \sigma_y\sqrt{1 - r^2_{xy}}$. As r_{xy} approaches 1 or -1, $\sigma_e \to 0$. Another method of defining r then is

$$r^2_{xy} = 1 - \frac{\Sigma(y - y')^2}{\Sigma(y - \bar{Y})^2}$$

where y' is given by the regression line.

In a correlation table let f_{xy} = frequency of an item in a cell, then the formula becomes fo r_{xy}

$$r_{xy} = \frac{\Sigma f_{xy} d'_x d'_y - \Sigma f_x d'_x \cdot \Sigma f_y d'_y}{\sqrt{[N\Sigma f_x d'^2_x - (\Sigma f_x d'_x)^2][N\Sigma f_y d'^2_y - (\Sigma f_y d'_y)^2]}}$$

where $N = \Sigma f_{xy}$, $d'_x = \dfrac{x - a}{c}$, $d'_y = \dfrac{y - b}{g}$, x and y are class marks, c is the class interval for the x's and g is the class interval for the y's. The coefficient of correlation is unchanged if we substitute $\dfrac{x - a}{c}$ for x and $\dfrac{y - b}{g}$ for y. If the variates are distributed in a normal bivariate probability distribution, we may test the hypothesis that ρ, the population coefficient of correlation, is zero or some other value ρ_1, by methods due to R. A. Fisher. To test the hypothesis $\rho = 0$ we calculate $t = r\sqrt{\dfrac{n}{1 - r^2}}$, where n the degrees of freedom is $N - 2$, N the number of paired variates, r is the sample coefficient of correlation and refer t to the tables of **Student's t distribution.** To test the hypothesis $\rho = \rho_1$, $\rho_1 \neq 0$, we calculate $W = \frac{1}{2}\log_e\dfrac{1 + r}{1 - r}$, $\bar{W} = \frac{1}{2}\log_e\dfrac{1 + \rho_1}{1 - \rho_1}$ and $\sigma_W = \dfrac{1}{\sqrt{N - 3}}$ and assume W is **normally distributed** with mean $\bar{W}$. In reality W is only approximately normal. The standard error of r, $\sigma_r = \dfrac{1 - \rho^2}{\sqrt{N}}$, has sometimes been used to test the hypothesis $\rho = \rho_1$. Its usefulness is questionable. (L.A.A.)

COEFFICIENT OF COUPLING. **Mutual Inductance.**

COEFFICIENT OF DETERMINATION. The coefficient of determination is defined as r^2_{xy}, the square of the **coefficient of correlation.** (L.A.A.)

COEFFICIENT OF DISCHARGE. Water discharged from an **orifice, weir, pipe,** etc., theoretically has a velocity which is directly proportional to the square root of the head of water causing flow through the opening. Actually, however, contractions in the stream, surface roughness, and other causes, result in the actual velocity being smaller than the theoretical. The theoretical velocity is identical with that of the velocity attained by a freely falling body. It is $\sqrt{2gh}$, wherein g represents the acceleration of gravity, and h the height of fall corresponding to the pressure head creating the discharge. The ratio of the actual velocity to the theoretical is the coefficient of discharge. The coefficient of discharge from circular orifices is affected by the diameter of the orifice, the head, the sharpness of the edge, the velocity of approach to the orifice, and other minor factors. (F.T.M.)

COEFFICIENT OF DISPERSION. Given n series containing s trials each, and let m_1, m_2, m_3, $\cdots$, m_n, represent the number of successes in each of these series. Let p be the **mean probability** in all $N = ns$ trials without specifying in any way the nature of the trials as either independent or dependent, and let $q = 1 - p$. Then we define the coefficient of dispersion D as the **expected value** of Q, $D = E(Q)$,

$$Q = \frac{\sum_{i=1}^{n}(m_i - sp)^2}{Npq}.$$

Usually D is called the Lexis ratio. The empirical value of D' obtained by using observed frequencies m'_1, m'_2, $\cdots$, m'_n is given by

$$D' = \frac{\sum_{i=1}^{n}(m'_i - sp)^2}{Npq},$$

assuming p is known. If p is unknown we obtain

$$D'' = \frac{N\sum_{i=1}^{n}\left(m'_i - \frac{sM}{N}\right)^2}{M(N - M)}, \quad M = \Sigma m'_i$$

on the assumption that all trials are independent and the unknown value of p may be approximated by M/N. We have mainly followed the exposition of Uspensky.

If the events are independent, three important cases arise. The probabilities may be the same within a series but may vary from series to series. This is the Lexis case, $D > 1$,

$$D = 1 + \frac{s-1}{npq} \sum_{i=1}^{n} (p_i - p)^2,$$

p_i = the probability in the ith series, and

$$p = \frac{p_1 + p_2 + \cdots + p_n}{n}.$$

The Lexis case is called a Lexis series of trials.

If the probability γ_i for the ith trial in each series is the same, we have a Poisson series of trials, $D < 1$,

$$D = 1 - \sum_{i=1}^{s} \frac{(\gamma_i - p)^2}{spq}, \quad p = \frac{\gamma_1 + \gamma_2 + \cdots + \gamma_S}{s}.$$

In a Bernoulli series of trials the probability is constant from trial to trial throughout all the series and $D = 1$. If $D = 1$ the series is said to have **normal dispersion,** $D > 1$ **supernormal dispersion,** $D < 1$ **subnormal dispersion.** In practical cases D'' is calculated since D is not available. Usually deaths, births, marriages, suicides and divorces form series which are Lexian if these series are taken over large regions or over different periods in a smaller locale. A Poisson series of trials seldom occurs in practice. (L.A.A.)

COEFFICIENT OF EXPANSION. Expansion.

COEFFICIENT OF FRICTION. Friction.

COEFFICIENT OF HEAT TRANSFER. Heat Transfer.

COEFFICIENT OF MEAN SQUARE CONTINGENCY. Let n_{rc} be the frequency in the cell formed by the intersection of the rth row and the cth column of an $r \times c$ contingency table, n_r = sum of the frequencies in the rth row and n_c = sum of the frequencies in the cth column and $N = \Sigma n_r = \Sigma n_c$, the total frequency in the table. We calculate

$$x^2 = N\left[\left(\sum \frac{n^2_{rc}}{n_r n_c}\right) - 1\right]$$

the summation being extended over all cells. The coefficient of mean square contingency, C.C., is

$$\text{C.C.} = \sqrt{\frac{x^2}{N + x^2}}$$

Its use is not recommended, unless the x^2 test shows lack of independence when the test of independence in a **contingency table** is applied. (L.A.A.)

COEFFICIENT OF MULTIPLE CORRELATION. The coefficient of multiple correlation $r_{1\,23}$ (in the case of three **variables** x_1, x_2, x_3) is defined by

$$r^2_{1.23} = 1 - \frac{\sigma^2_{e1}}{\sigma^2_{x1}}, \quad \sigma^2_{e1} = \frac{\Sigma(x_1 - x'_1)^2}{N},$$

$$\sigma^2_{x1} = \frac{\Sigma(x_1 - \bar{X})^2}{N},$$

$\bar{X}$ **is the mean,** N triplets of values $(x_{11}, x_{21}, x_{31}), \cdots (x_{1N}, x_{2N}, x_{3N})$, $x'_1 = b_1 + b_2x_2 + b_3x_3$. By permuting x_1, x_2, and x_3 we obtain similar formulas for $r^2_{2.13}$ and $r^2_{3.12}$. The coefficient of multiple correlation measures the dependence of x_1 on x_2 and x_3, $0 \leq r^2_{1\,23} \leq 1$. Always $r^2_{1.23} \geqq r^2_{12}$ or r^2_{13}. Another formula for $r^2_{1.23}$ is

$$r^2_{1.23} = \frac{r^2_{12} + r^2_{13} - 2r_{12}r_{13}r_{23}}{1 - r^2_{23}}.$$

To test the hypothesis $R^2_{1\,23} = 0$, $R_{1\,23}$ being the population value of the multiple coefficient of correlation we calculate

$$F = \frac{\Sigma(x'_1 - \bar{X}_1)^2/2}{\Sigma(x_1 - x'_1)^2/N - 3}$$

with **degrees of freedom** $n_1 = N - 2$, $N - 3$. Then F is referred to tables of **Snedecor's F distribution.** If the value of F so determined is greater than the value of F at the 5% level of significance from Snedecor's tables, we reject the hypothesis $R^2_{1\,23} = 0$.

For m variables $x_1, x_2, \cdots, x_m$, $r^2_{1\,23\ldots m}$ is defined by

$$r^2_{1.23\cdots m} = 1 - \frac{\sigma^2_{e1}}{\sigma^2_{x1}}$$

where σ^2_{e1} and σ^2_{x1} are defined as before and $x'_1 = b_1 + b_2x_2 + \cdots + b_mx_m$. The test of significance becomes

$$F = \frac{\Sigma(x'_1 - \bar{X})^2/m - 1}{\Sigma(x_1 - x'_1)^2/N - m - 2}$$

$$= \frac{r^2_{1\,23\cdots m}/m - 1}{(1 - r^2_{1.23\cdots m})/N - m - 2}$$

$n_1 = m - 1$, $n_2 = N - m - 2$. The easiest computational process for finding $r^2_{1.23\ldots m}$ is presented in the **Doolittle method of solving normal equations.** (L.A.A.)

COEFFICIENT OF NON-DETERMINATION. The coefficient of non-determination is $1 - r^2_{xy}$, where r_{xy} is the **coefficient of correlation.** (L.A.A.)

COEFFICIENT OF PARTIAL CORRELATION. The coefficient of partial correlation $r_{12\,3}$ is defined as the **correlation** between x_1 and x_2 when x_3 is kept constant in a certain way or more precisely let $x'_1 = b_1 + b_3x_3$, $x'_2 = c_1 + c_3x_3$ then $r_{12\,3}$ is the correlation between $x_1 - x'_1$ and $x_2 - x'_2$. This definition gives us the formula

$$r_{12\,3} = \frac{r_{12} - r_{13}r_{23}}{\sqrt{(1 - r^2_{13})(1 - r^2_{23})}}, \quad -1 \leqq r_{12\,3} \leqq 1.$$

Similar formulas are evident for $r_{13\,2}$ and $r_{23\,1}$. The partial coefficient of correlation always lies between -1 and $+1$. In the case of m **variables** $x_1, x_2, \cdots, x_m$, $r_{12\,34\cdots m}$ is defined as the correlation between $x_1 - x'_1$ and $x_2 - x'_2$ where

$$x'_1 = b_1 + b_3x_3 + b_4x_4 + \cdots + b_mx_m$$

and

$$x'_2 = c_1 + c_3x_3 + \cdots + c_mx_m$$

It is found most simply by the formula

$$r_{12\,34\cdots m} = \sqrt{\beta_{12\,34\cdots m} \cdot \beta_{21\,34\cdots m}}$$

$\beta_{12.34\cdots m}$, and $\beta_{21.34\cdots m}$ are the regression constants

$$t_1 = \beta_{12\,34\cdots m}t_2 + \beta_{13} \cdots t_3 + \cdots + \beta_{1m} \cdots t_m$$
$$t_2 = \beta_{21.34\cdots m}t_1 + \beta_{23} \cdots t_3 + \cdots + \beta_{2m} \cdots t_m$$
$$t_i = \frac{x_i - \bar{X}_i}{\sigma_{x_i}}.$$

The most efficient computational technique in finding $r_{12.34\cdots m}$ is given under **Doolittle's method of solving normal equations.** To test the hypothesis $r_{12\,34\cdots m} = 0$ we apply **Student's t test**

$$t = \frac{r}{\sqrt{1 - r^2}}\sqrt{N - m}$$

with **degrees of freedom,** $n = N - m$ where r is the sample value of the coefficient of partial correlation. (L.A.A.)

COEFFICIENT OF PERFORMANCE. **Refrigeration.**

COEFFICIENT OF SKEWNESS. **Skewness.**

COEFFICIENT OF VARIATION. The coefficient of variation of a distribution, V, is defined as the **standard deviation** divided by the **mean**, $V = \frac{\sigma_x}{\bar{X}}$. Ordinarily its value is less than 1. Some authors define it as $V = 100 \frac{\sigma_x}{\bar{X}}$ in order to avoid decimals. (L.A.A.)

COEFFICIENT OF VELOCITY. **Orifice.**

COELATA. A group of free-living flatworms which have an intestine. (See **Turbellaria.**) (A.W.L.)

COELENTERATA. The **hydroids, jellyfishes, sea anemones, corals,** and related animals. These forms make up a major division of the animal kingdom of simple structure. The body is developed from only two germ layers and is radially symmetrical. The alimentary track is sac-like, with a single opening, but sometimes has complex tubular branches. The nervous system is a scattered network of cells connected by their slender processes. Coelenterates have peculiar stinging cells (**cnidoblasts**) which discharge irritating **nematocysts.** Most species are marine and all are aquatic.

Two forms of individuals occur in this phylum, the **polyp** or hydroid and the **medusa.**

The economic importance of the phylum is limited principally to the corals. Precious coral is sold in considerable quantities and the rock corals have built up many of the oceanic islands.

The principal subdivisions of the phylum are the following:

Class **Hydrozoa** (Hydromedusae). Both polyps and medusae occur in these species, usually alternating in a reproductive cycle. Species are often colonial. In colonies individual polyps or hydranths are borne on branches of a common stalk which also gives rise to reproductive individuals or **blastostyles** from which medusae arise. All individuals are joined by the continuous digestive tract. Most species are small but the **Portuguese man-of-war** and a few others are large.

Class **Scyphozoa** (Scyphomedusae). The **jellyfishes.** Usually free-swimming species of moderate to large size. All individuals are medusae. Mostly marine.

Class **Actinozoa** (Anthozoa). **Sea anemones, sea feathers, corals** and allied species. Solitary or colonial marine species. The individuals are polyps. Colonies of some species build up massive hard deposits inside or outside of the body. (A.W.L.)

COELOM. The true body cavity, formed by the splitting of the middle **germ layer** of the body (mesoderm) and lined with a definite layer of cells.

The coelom is well developed in **annelid** worms, where it appears as a series of **metameric** chambers. It is of limited extent in other invertebrates but in the vertebrates gains great development. Here it is divided into a thoracic and an abdominal cavity and in the terrestrial species the thoracic cavity is further divided into pleural cavities containing the lungs and a pericardial cavity containing the heart. The abdominal or peritoneal cavity contains principally the greater part of the digestive tract.

Excretory organs open from the coelom in the annelids and lower **vertebrates,** and the liquid which it contains is apparently supplementary to the blood. In all cases the cavity furnishes a space into which developing organs may expand in complex animals. (A.W.L.)

COELOMATA. Animals which have a **coelom.** The term embraces the phyla **Bryozoa, Brachiopoda, Phoronidea, Chaetognatha, Echinodermata, Mollusca, Annelida, Arthropoda,** and **Chordata.** (A.W.L.)

COELOMODUCT. A tubule opening at one end into the coelom and at the other on the surface of the body. It occurs in a simple form in some **annelid** worms as an excretory organ and in other species is associated with the **nephridial** tubule to form a more complex excretory structure. Coelomoducts are regarded as the evolutionary forerunners of the excretory tubules of **vertebrates.** (See **Excretory System.**) (A.W.L.)

COELOSTAT. In many types of astronomical research it is desirable to have the main instrument stand still. To accomplish this purpose and also allow for the apparent motion of the **celestial sphere** it is necessary to reflect the light by a moving mirror from the object in question into the instrument. Such a device which "makes the sky stand still" is known as a coelostat. In the coelostat a mirror is mounted parallel to the polar axis of an **equatorial** mounting. The axis is rotated by clock work from east to west at such a rate that it would complete one rotation in 48 hours of **sidereal time.** Since the celestial sphere rotates from west to east once in 24 hours of sidereal time, and reflection doubles the angle, this rotation of the polar axis will compensate for the apparent rotation of the celestial sphere. With one single mirror mounted in the manner described the direction in which the light will be reflected will depend entirely upon the declination of the object observed. To obtain any desired direction of reflection a second mirror is employed to send the stationary beam from the first mirror in the desired direction.

In case it is desired to hold an image of the sun apparently stationary the polar axis must be rotated once in 48 hours of solar time. Such an instrument is known as a heliostat. Other types of mounting, used for particular purposes, are known as siderostats. (W.K.G.)

COENENCHYME. The middle and outer tissues of certain coelenterates (**Alcyonaria**). (A.W.L.)

COENOCYTIC CELLS. There are many plants which are composed of **cells** each containing many **nuclei.** In some cases the entire plant is a single cell, no cross-walls being formed until **reproduction** takes place. Multinucleate cells of this sort are called coenocytic cells. The **Phycomycetes** contain many plants of this kind, as do also the green **algae.** (B.S.M.)

COERCIVE FORCE. **Magnetism.**

CO-FACTOR OF A DETERMINANT. **Determinants.**

COFFEE. *Coffea arabica.* Rubiaceae. Probably the the coffee plant is a native of Ethiopia. In early historical times it was recognized as a valuable drink by the Arabs, who were responsible for its introduction into Europe. The cultivation of coffee slowly spread throughout the Old World and later, beginning in 1720, in the New World. The plant is a small tree with dark green leaves and fragrant white star-like flowers borne in axillary clusters. The fruits are about ½" long, have a deep crimson skin and a yellow pulp surrounding the two seeds within. These seeds are the coffee beans.

The trees grow best in well-drained soil in regions entirely free from frost. In cultivation, the trees are grown from seed and begin bearing fruit in 4 or 5 years, continuing to bear up to 30 years. Seed production, once started, is more or less continuous throughout the year. The berries are gathered from the trees by threshing, or by hand, a costly operation in regions

where labor is expensive. The berries are separated from any dirt present by washing, the heavy berries sinking to the bottom and the trash washing away. After this the pulp surrounding the seeds is largely removed by machines, and the seeds allowed to ferment slightly. They are then spread out to dry in the sun, or sometimes they are dried artificially. This permits the removal of any remaining pulp and of the thin inner skin which surrounds the seeds. The seeds are then ready to be bagged and shipped.

Before they are ready for the consumer the coffee beans must be carefully roasted. Roasted coffee contains from 1–2% of the alkaloid **caffeine,** which acts as a diuretic and as a cerebral stimulant. The aroma of coffee is due to an oily substance, caffeol, which is quickly oxidized when exposed to the air. By means of modern vacuum packing, this substance is preserved unchanged. Coffee also contains **glucose, dextrin,** and **protein.**

Brazil is one of the greatest coffee-producing countries in the world. The only important product of the coffee tree is the widely used beverage.

In many Eastern countries other species of coffee, as *Coffea liberica* and *robusta,* are planted to some extent, because of their greater resistance to diseases which have seriously reduced the better *Coffea arabica* plantations. (R.M.W.)

COFFER FISH. Pisces, Teleostei. Strangely shaped tropical marine fishes (**Pisces**) whose bodies are enclosed in bony plates. (A.W.L.)

COFFERDAM. A cofferdam is a structure of a temporary nature, used to exclude water from an otherwise submerged area, for the purpose of preparing for **foundations** or for other subaqueous construction. Cofferdams are frequently required both above and below the site of a permanent dam in order to by-pass the stream through a temporary channel during the construction period. The simplest cofferdam is an earth dyke which should be used only in shallow water where there is little or no current. Facing an earth cofferdam with sand bags or constructing it entirely of sand bags will make it serviceable when there is a current which would wash away loose materials.

If the depth of the water to be held back by the cofferdam exceeds that for which the earth dam is practicable (approximately 5′) other types must be constructed. Sheet piling (see **Piles**) can be used to form a cofferdam around a site by erecting it in double parallel walls, the space between being filled with sand or gravel and clay. This mixture is thoroughly tamped in order to form a solid filling. This materially adds to the stability of the structure. Where a small area is to be unwatered, a single wall of sheet piling, internally braced, may be erected around the site.

When cofferdams, constructed of sheet piling, are to rest on hard bottom, a timber framework is required to hold the sheeting in place. These frames are generally built on shore, floated into position and sunk into place. Sheet piling is then placed around the outside and banked with earth.

After the cofferdam has been completed it must be unwatered by pumps. As sheet piling is not entirely water-tight, leakage must be pumped out in order to keep the interior as dry as possible. (C.W.C., F.T.M.)

COG. Obsolete term for gear tooth. (See **Spur Gearing.**)

COHERENCE. Interference.

COHESION. Adhesion.

COIL. This term applies to one or more turns of conductor when wound as a definite unit of an electrical circuit. Thus we have the **choke coil,** or as it is sometimes called, impedance coil, as a number of turns of wire forming a coil used primarily for its reactance effect. The **transformer** is a unit of one or more coils used for transferring electrical energy by magnetic induction. Coils are particularly important in communications circuits where they serve in the above capacities but also form parts of the tuned circuits which make possible our complex systems. While the coil is ordinarily used for its inductive properties it inherently has both resistance and distributed capacity. The former is because of the resistance of the wire of which it is wound. The latter is due to the potential difference between turns which are separated by the turn insulation. At high frequencies this distributed capacity becomes extremely important and limits the usefulness of a given coil. Various special winding schemes have been used to minimize this effect. Electrical machines have coils as essential components; thus we have field coils, armature coils, etc. (L.R.Q.)

COIL CHAIN. Chain.

COINCIDENCE METHOD. Physical Measurements.

COINING. Press-Working.

COIR. The outer husk of the **coconut** is composed of coarse rough brown fibers, and is known as coir. These fibers are light, tough, and extremely resistant to heavy wear, as well as to wetting. They are therefore much in demand for making doormats, cordage, coarse matting, and stuffing for upholstery. Coarse brushes are made from shorter fibers. India and Ceylon supply the greater part of the crop. (R.M.W.)

COITUS. Sexual intercourse, **copulation.** (R.S.M.)

COKE. Coke is a solid product obtained by heating **coal** (in practice, bituminous coal) in a furnace without access of air. Coal is composed of moisture, ash, "fixed" carbon, and hydrocarbons which are volatile, in that they are distilled from the coal by the application of heat. When coal is subjected to intentional and controlled distillation, the volatile matter and moisture are driven off and the residue, consisting of the fixed carbon and the ash-forming substances, is commercial coke. The volatile products of the distillation are comprised of water, coal tar, and gas. The coal tar is a complex mixture, containing many substances of value to industry, especially to the chemical industry. The gas is widely used as an industrial fuel.

Since the smoke-producing constituents are driven off during the "coking" of the coal, the coke forms a desirable fuel for stoves and furnaces in which conditions are not suitable for the complete combustion of the bituminous coal itself. Coke may be burned with little or no smoke under combustion conditions which would result in a large amount of smoke were bituminous coal the fuel. Coke is the standard fuel for metallurgical purposes, i.e., cupola and blast furnace heating.

The solid residue remaining from the refining of petroleum by the "cracking" process is a form of coke. Petroleum coke has many commercial uses besides being a fuel, and is employed in the manufacture of dry cells, electrodes, etc. Gas works engaged in the manufacture of coal gas also have a coke end-product. This is called gas house coke. (F.T.M.)

COKITE. The term applied by Lacroix in 1917 to natural coke, the result of the **contact metamorphism** of coal beds. (R.M.F.)

COL. A relatively small area about midway between two cyclones and two anticyclones where the pressure

gradient is very weak and winds are usually light and variable. It is the point of intersection between a trough line and a wedge line. (P.E.K.)

COLA. *Cola acuminata,* and other species. Sterculiaceae. Cola nuts are the **cotyledons** of trees growing native in the West African forests. The natives chew the fresh nuts, finding therein stimulation to prevent fatigue. From the dried nuts is made a beverage used in Africa.

The nuts contain up to 3% **caffein** and 2% **tannin,** as well as small amounts of **theobromine.** They are used in the manufacture of beverages. (R.M.W.)

COLCHICINE. An alkaloid obtained from the seeds or corm of the autumn-crocus, *Colchicum autumnale.* Liliaceae. The plant grows wild in Europe and North Africa and has been introduced into cultivation. It should not be confused with *Crocus,* a member of the Irish Family (Iridaceae), several species of which are grown widely as early-spring-flowering or as autumn-flowering perennials. These are tiny plants with narrow leaves and flowers on short stalks. The autumn-crocus is a much larger plant with leaves up to 12″ long and 2″ wide. The leaves appear in the spring on a stalk which also bears the ripening fruit. The fruit was formed in the previous fall and has remained underground on the top of the corm. Seeds are collected for the market in August as the leaves dry up and die. In September several flowers grow out of the corm. The flower has no stalk and consists of a corolla tube 4 or 5″ long partly underground and a limb of six segments often 4″ across. Corms are collected for the drug market in early August, cut into thin slices and quickly dried to kill the cells and prevent metabolic activity which destroys the alkaloid.

Colchicine is very poisonous, producing violent gastroenteritis when taken internally, even in small amount. Its use has been mainly in the treatment of **gout.** The sudden emergence of the drug from relative obscurity is due to the recent discovery that it interferes with **cell division** by destroying the spindle mechanism. The two chromatids which represent one chromosome at the metaphase stage fail to separate and do not migrate to the poles (ends) of the cell. Each chromatid becomes a chromosome *in situ.* The entire group of new chromosomes now form a resting nucleus and the next cell division reveals twice as many chromosomes as before. The cell has changed from the diploid to the tetraploid condition. Applied to germinating seeds or growing stem tips in concentrations of about 1 gram in 10,000 cc. of water for 4 or 5 days, colchicine may thus double the chromosome number of many or all of the cells, producing a tetraploid plant or shoot. Offspring from such plants may be wholly tetraploid and breed true. Tetraploid plants are larger than diploid plants and often more valuable. The alkaloid has also been used to double the chromosome number of sterile hybrids produced by crossing widely separated species of plants. Such plants, after colchicine treatment, contain in each cell two complete diploid sets of chromosomes, one from each of the parent species, and become fertile, pure-breeding hybrid species. (P.A.W.)

COLD FRONT. Any boundary surface separating cold air from warmer air along which cold air is actively displacing the warm air. (See **Fronts.**) (P.E.K.)

COLD SECTOR. Temperate-zone cyclones usually involve two air masses. That part of the cyclone occupied by the cold air is known as the cold sector (in contrast with the area occupied by the warm air which is the warm sector). Cold sectors constitute more than ½ and often practically all the area covered by a cyclone. (P.E.K.)

COLD WORKING. An important property of ductile metals such as iron, copper, and aluminum is their ability to undergo severe deformation at normal temperatures without rupture. Cold rolling, forming, stamping, extrusion, and wire drawing are among the many processes involving cold working of metals. With the exception of metals that **recrystallize** at or near room temperature, for example, lead, cold working increases the hardness and strength and reduces the ductility. The strength thus developed in processing is often used to meet the strength requirements of the part. (See **Temper.**) Alloys processed in this manner are called work-hardening type alloys—in contrast with heat-treating alloys which are given a final heat treatment to develop required hardness or strength. (R.H.H.)

COLEMANITE. The mineral colemanite is a **borate** of **calcium** corresponding to a formula which is perhaps best represented as $Ca_2B_6O_{11}\cdot 5H_2O$. It occurs either as massive deposits or in **monoclinic** crystals. It has a subconchoidal fracture; hardness, 4–4.5; specific gravity, 2.42; vitreous to adamantine luster, may be colorless to milky white, grayish or yellowish; transparent to translucent. Colemanite was found originally in Death Valley, Inyo County, California, and has since been found rather widely distributed in San Bernardino, Los Angeles, Kern and Ventura Counties, California, as well as in Clark, Esmeralda and Mineral Counties in Nevada.

Colemanite was, until the discovery of **kernite,** the chief source of borax. Kernite, $Na_2B_4O_7\cdot 4H_2O$, because of its easy solubility in water, has displaced very largely other boron-bearing minerals as a source of borax. Colemanite, kernite and **inyoite** (probably $2CaO\cdot 6B_2O_3\cdot 13H_2O$) are lake deposits associated with other and rarer boron minerals, laid down during periods of volcanic activity or resulting from the leaching of the adjacent Tertiary sedimentary formations. Colemanite was named for Mr. William T. Coleman of San Francisco; Kernite and Inyoite were named from Kern and Inyo Counties, California. (E.S.C.S.)

COLEOPTERA. The beetles. An order of insects usually recognizable by the thickened wing covers which meet in a straight line down the middle of the back. These wing covers, or elytra, are modified fore wings. In most species of beetles they are thickened or horny but in some they are soft. In some species they are divergent and in some they are short, leaving much of the abdomen exposed. The typical condition of the elytra is found outside of this order only in the earwigs. Beetles have biting mouth parts and a complete metamorphosis in which the larval stage is often a grub.

This order of insects is the largest group of its rank in the animal kingdom, with almost 200,000 described species. It embraces almost the entire range of adaptation of the class, although very few beetles are parasitic. Many species are of economic importance. (A.W.L.)

COLEOPTILE. In the **seeds** of grasses the primitive **bud** or **plumule** is enclosed in a protective sheath called the coleoptile. During germination of the seed this coleoptile elongates, pushing its way out of the seed and up through the soil. It is very sensitive to light, growing directly towards a beam of light. (R.M.W.)

COLIC. This is a general term denoting abdominal pain which comes on quickly, is sharp and penetrating in character, intermittent, brief, and cramp-like. Biliary colic is a sharp severe pain which occurs with the passing of gallstones through the **bile** passages. Lead or Painter's colic occurs in **lead** poisoning and is associated with increased intestinal peristalsis. Renal colic occurs with the passing of a stone through the **ureter.** Treatment of colic is symptomatic during an attack. Atropine is used

to relieve muscle spasm, and morphine may be necessary for severe pain. (D.M.H.)

COLITIS. **Inflammation** of the wall of the **colon** which may be due to a number of causes. Amoebic colitis or amoebic dysentery is colitis caused by the parasite *Entamoeba Histolytica* (see **Dysentery**). Mucous colitis is a chronic disorder of the colon commonly seen as a manifestation of a **psychoneurosis.** It is characterized by overactive **peristalsis** of the intestinal tract, the passage of mucus, constipation or diarrhea, and spasm of the walls of the colon. Ulcerative colitis is widespread infection of the colon with ulceration of its walls accompanied by diarrhea with blood and **pus,** fever, and weight loss. Its exact cause is unknown, but it belongs to the group of **psychosomatic diseases.** The disease is chronic with acute exacerbations, and responds poorly to treatment. **Sulfonamides** plus general supportive measures—high-caloric high-vitamin diet—are used. (D.M.H.)

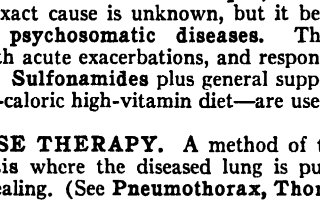
COLLAPSE THERAPY. A method of treatment in **tuberculosis** where the diseased lung is put at rest to promote healing. (See **Pneumothorax, Thoracoplasty.**) (R.S.M.)

COLLAR. A fold or ridge of tissue more or less completely encircling the body behind its anterior end. In the snails, cuttle fishes, and related mollusks the ventral edge of the mantle is called the collar and in *Balanoglossus* (**Chordata**) the region of the body between the proboscis and the trunk is so named. (A.W.L.)

COLLAR CELL. A cell bearing a **flagellum** at one end, surrounded by a high membrane. Some of the 1-celled animals and the choanocytes of sponges have this form. (A.W.L.)

COLLECTOR. **Klystron.**

COLLEMBOLA. The spring-tails. An order of primitive wingless insects characterized by a forked appendage at the tip of the body which is used in leaping. This



Spring-tail.

appendage is bent forward beneath the body and when released snaps sharply down and back, projecting the animal into the air.

Spring-tails are small and delicate. They are found mostly in moist places on the ground or on bark, though a few species live in dry hot situations. The snow flea, which sometimes appears in large numbers on the surface of snow, is a spring-tail. Some species are found on the surface of water. (A.W.L.)

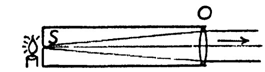
COLLENCHYMA. **Stem.**

COLLES' FRACTURE. A fracture of the arm near the wrist, in which the radius is broken in its lower quarter. It is one of the most common fractures and occurs usually from a fall on the outspread hand, or a direct blow against the wrist. (D.M.H.)

COLLET. **Drilling.**

COLLETERIAL GLANDS. Glands associated with the female reproductive system of **insects.** They secrete materials which cement the eggs together or form a protective covering over them. (A.W.L.)

COLLIMATOR. An optical arrangement for producing parallel rays of light. A common form consists of a converging **lens,** at one of whose focal points is placed



Divergent rays from slit S rendered parallel by objective O.

a small source of light, usually a pinhole or narrow slit upon which light is focused from behind. Rays diverging from this focal point emerge from the objective **lens** in a parallel beam. The slit or other source is viewed through the collimator without parallax, since it appears at an infinite distance. The arrangement is very generally used on **spectroscopes** and spectrometers. (L.D.W.)

COLLISION. As used in physics, this term refers to any encounter between free bodies in which they come near enough to exert a mutual influence, generally with exchange of energy. It does not necessarily imply actual contact. The process is subject to conservation of momentum, and in an "elastic collision," also to conservation of energy. In the latter case, if the initial velocities are given, the velocities of the bodies after collision can be calculated by applying these two conservation principles. The subject is of special significance in the case of **atoms, molecules,** etc. Collisions of this type between two particles A and B are denoted as of the "first class" or the "second class" according as (1) particle A loses kinetic energy and thereby affects B in some way, or (2) particle A communicates to B energy which it has by virtue of excitation or ionization. In either case B may receive additional kinetic energy or may be excited or ionized by the energy given to it by A. (L.D.W.)

COLLOBLAST. An adhesive cell used by the comb jellies (**Ctenophora**) in catching prey. Lasso cell. (A.W.L.)

COLLODION PROCESSES. The use of collodion in photographic emulsions (see **Photographic Emulsions**) dates from 1851 when Frederick Scott Archer published the details of his wet collodion process. While this process is no longer used in general photography, it is still widely used in making the half-tone negatives required in photoengraving. A brief description of the wet collodion process follows: A clean glass plate is first coated with collodion containing potassium iodide and potassium bromide. It is next sensitized by immersion in a solution of silver nitrate. It is then placed in a plate holder—specially designed for the handling of the wet plate—and the exposure made. After exposure it is developed in a solution of ferrous sulfate and fixed in potassium cyanide, or in hypo, washed and dried. The wet collodion process, as it is used by the photoengraver, results in a negative of high density and extreme contrast, high resolution and with an extremely fine grain. These characteristics render wet collodion well adapted to the requirements of photoengraving and it is only with recent years that gelatino-bromide emulsions of similar characteristics have been made available. These are now rapidly replacing the less convenient and less reliable wet collodion process.

Collodion printing-out paper was introduced by Obernetter of Munich in 1867 and was for many years the favorite printing process of the portrait and professional photographer. It was in general use until the early years of the present century when it was gradually replaced by developing-out paper. (C.B.N.)

COLLOIDAL STATE. All living matter is built up of colloidal materials, and almost all of our food, clothing and shelter materials are colloidal. The colloidal state is determined by the size of the particles of the

substance, being intermediate in size between visibly suspended particles and invisible molecules. Turbid suspensions, visible to the naked eye or by means of the ordinary microscope, consist of particles of 250 millimicrons (250×10^{-7} cm.) or larger diameter, and molecules invisible by the **ultramicroscope** are of 5 millimicrons (5×10^{-7} cm.) or smaller diameter. True suspensions, such as fine clay in water, settle on standing, but colloidal suspensions exhibit continuous random motion—so called Brownian movement—of the suspended particles. **Diffusion** through animal membranes or parchment paper is negligible for substances in the colloidal state, whereas for true solutions diffusion is marked. Phenomena related to vapor pressure, freezing point, osmotic pressure of solvent or dispersion medium are marked in the case of true **solutions** but negligible for emulsions, like milk, emulsoids like gelatin, boiled starch, silicic acid, and suspensoids like **arsenious** sulfide sol, **sulfur** sol, **gold** sol, **ferric** hydroxide sol, clay (**ammonium** hydroxide) sol. In the case of emulsoid sols, the **surface tension** is lower than that of the dispersion medium, the **viscosity** is greater than that of the dispersion medium, and, in the case of organic emulsoid sols, the solid may be recovered from and redispersed in the medium at will, that is, they are reversible—for example, gelatin-water sol—and in the case of inorganic emulsions the system is non-reversible—for example, silicic acid-water sol. Particles of colloidal dimensions possess an **electric charge**, either positive or negative, and by treatment with certain **electrolytes** or colloids or by action of the electric current the electric charge is neutralized and the particles are coagulated.

The subdivided phase, corresponding to the solute in solutions, is called the dispersed phase, and the enveloping phase, corresponding to the solvent in solutions, the dispersing or continuous phase. Where both phases are continuous, the distinction between dispersed and dispersing phases merges into an interlacing system. Most of the stable colloidal systems are dependent for their stability on the presence of a protective colloid or stabilizer. Thus gelatin is added to milk and to ice-cream to stabilize the colloidal system, and mustard flour (1.0%) and egg yolk (8.0%) serve as stabilizers in mayonnaise dressing where as much as 75% of oil is dispersed in 16% of water phase, which phase contains acetic acid and salt about 1.0 and 1.5 parts per 100 of the total mayonnaise mixture (Corran, 1935).

A jelly is a completely transparent elastic mass; a gel is a flocculent and gelatinous precipitate. Jellies may be obtained without marked interference with the **equilibrium** in the solution; formation of gels disturbs radically the equilibrium in the solution. Fruit jellies and soap jellies are familiar examples; silicic acid gel is produced by addition of hydrochloric acid to sodium silicate solution. In using **pectin** for the production of jellies, the practical conditions are: maximum concentration of pectin 0.97% of the weight of the finished jelly; pectin-sugar ratio definite for a given pH (see **Reactions Involving Recombination of Ions**); sugar 50% to 70%; maximum pH 2.9 to 3.1; with 50% dry material at least 1.2% pectin, with 70% dry material 0.6% pectin.

Finely divided clay forms a colloidal suspension—is peptized—in water when treated with ammonium hydroxide or with tannin. Acheson made use of this principle when he used tannin to peptize finely divided graphite for lubricants. He relates that upon looking up the literature, he could find only one instance of the use of vegetable matter in clay working. That was in the Bible where the Egyptians used straw in the making of bricks. Since straw contains no tannin he wondered what the effect could be. Upon boiling straw with water he found that about half of the straw dissolved in water, and that the solution produced the same results with clay that tannin produced. He states that he found, in one case, that a sun-dried brick made of treated clay was of greater tensile strength than a burned one made of the untreated clay.

Particles of a given substance may be brought into the colloidal state in one of two ways, namely, (1) by comminution or dispersion from macroscopic size—visible to the eye—to ultramicroscopic or colloidal size, (2) by precipitation or condensation from sub-ultramicroscopic, molecular or solution size to colloidal size, either without or with accompanying particles large enough to settle out of the medium.

Dispersion Processes. 1. The simplest method of accomplishing dispersion is by grinding the solid (or liquid) material with the liquid medium until particles of the required size are ultimately obtained. The colloid mill (Plauson, 1921) is used for such purpose, as in mixing paints and pastes, regenerating milk from milk powder, dispersing cellulose in **sodium** hydroxide and **carbon disulfide** for the production of xanthates for viscose, and in emulsifying fats and waxes. 2. **Zinc** sulfide, **cupric** ferrocyanide, **stannic** acid, **silver** chloride are examples of precipitates which, when washed on the filter paper until the accompanying soluble electrolyte has been removed, form colloidal solutions and pass through the pores of the paper. Since this is usually to be avoided in practice, the washing is then done with an electrolyte which does not conflict with the treatment to follow. Frequently **ammonium** nitrate solution is used. 3. A peptizing agent is frequently employed. **Tannin** is peptized by water, and by glacial **acetic acid.** Soaps are peptized by water. Gelatin swells in cold water but is not peptized, but is peptized in warm water. Starch, although insoluble in cold water, behaves similarly to gelatin with warm water (63° to 74° C., depending upon the kind of starch). Cellulose nitrate swells in ethyl alcohol and not in ether, but is peptized in ethyl alcohol-ether mixture. Clay is peptized by ammonium hydroxide, and it is held by some that the action of sodium hydroxide on **zinc, aluminum,** and **chromium** hydroxides is one of peptization. 4. Water-peptizable colloidal substances such as gelatin, dextrin, gum arabic, and soap peptize many precipitates, and are often called protective colloids. Gelatin in the solution prevents the precipitation of silver dichromate upon mixing silver nitrate and potassium dichromate solutions. (See Condensation Processes, below.) 5. When dilute **silver** nitrate and dilute **potassium** bromide solutions are mixed so that there is a slight excess of either solution, silver bromide is peptized Acheson's oil-dag and aqua-dag are suspensoids of graphite in oil or water containing a protective colloid, **tannin.** Oil-dag contains about 15% of a "deflocculated graphite," and is used in dilute solution in lubricating oil (about 0.1% **graphite**). Bearings gradually become coated with a thin layer of graphite.

Condensation Processes. 1. When a solution of **ferric** chloride is poured into a relatively large volume of boiling water, colloidal ferric hydroxide is formed. The ferric hydroxide sol does not react with hydrogen sulfide nor with **potassium** ferrocyanide, and like all colloidal substances does not pass readily through animal membranes or parchment. 2. When **hydrogen sulfide** is passed into a solution of **arsenious** oxide, arsenious sulfide sol is formed which in the absence of an electrolyte may be made of the high concentration of 60 grams of arsenious sulfide per 100 grams of water. Upon addition of **hydrochloric acid,** arsenious sulfide coagulates and is precipitated. 3. When hydrochloric acid is added to **sodium** silicate solution either silicic acid sol or silicic acid gel is formed. 4. When hydrogen sulfide solution is treated with an oxidizing agent, for example, the proper concentration of nitric acid, sulfur sol is formed. 5. When **gold chloride** very dilute solution (0.01% to 0.001% of gold chloride) is made slightly alkaline (say by the addition of magnesium oxide) and then treated with a reducing agent, for example, formaldehyde or sodium hydrosulfite ($Na_2S_2O_4$), red gold

sol is formed. 6. Use of a protective colloid in solution prevents the formation of the ordinary and expected precipitate in many cases and causes the formation of the expected substance as colloidal sol. Silver nitrate (0.6 gram per liter) and **potassium** dichromate (0.5 gram per liter) to one of which is added 0.1 volume of hot gelatin solution (2 grams per 100 milliliters of water) are mixed with stirring silver dichromate sol is formed. 7. When an electric arc is formed under water between two metallic rods, particles of the metal of colloidal size are formed along with more or less separation of free metal. A protective colloid increases the stability. If the metal vaporizes and then condenses to the colloidal state this is strictly speaking a condensation process, if otherwise, a dispersion process.

The disappearance of the colloidal state of a substance may be accomplished in either of two directions, namely, by the colloid passing into solution or into suspension. Practically, the latter is the more important method. Coagulation, agglomeration or precipitation is readily brought about by discharge of the electric charge on the particles. Ions carrying a charge of opposite sign to that carried by the colloidal particles are active precipitants, and the higher the valency of the ion the more effective (Linder-Picton-Hardy). When the colloidal particles are made neutral the conditions are least favorable to their stability. For colloidal arsenious sulfide, which is negatively charged in water, the coagulating power of potassium iodide (K^+I), calcium chloride ($Ca^{2+}Cl_2$), aluminum chloride ($Al^{3+}Cl_3$) is in the ratio of 1:80:1500 (Svedberg); and for colloidal ferric hydroxide, which is positively charged in water, the coagulating power of potassium chloride (KCl^-), potassium sulfate ($K_2SO_4^{2-}$) is in the ratio of 1:45. The active ion is carried down with the precipitated particles. Oppositely charged colloids, e.g., arsenious sulfide and ferric hydroxide, when mixed, precipitate each other. Other methods of coagulation are by migration of colloidal particles to and their discharge at electrodes, and by heating, as in the case of egg albumin. Coagulation is usually irreversible, especially when caused by electrolytes.

An interesting case, operating on a large scale in nature, of the precipitation of a colloidal system by an **electrolyte** is that of the action of sea water on the mud and silt of river water entering the ocean. When river water flows into the ocean the former, on account of its lower specific gravity, tends to flow over the latter and spread out in widening range. As the current diminishes some of the suspended mud and silt settles out, but the finer colloidal particles are coagulated by the electrolyte of the sea water and form deltas at the mouths of rivers.

Scope and Importance of the Colloidal State. As was stated in the beginning all living matter, whether animal or plant, is made up of colloidal materials and is sustained by colloidal processes. Of similar importance is colloidal chemistry in everyday living, in almost all of our foods, such as proteins and starches, in our clothing, whether of natural or synthetic origin, and in our shelter materials, such as wood, bricks, concrete. When there is added to these other common things and operations of everyday life, such as pottery and porcelain, paper, rubber and leather, and cooking and washing, where colloidal matter and processes operate, it is evident how broad is the scope and how great is the importance of the field. To these there must also be added other applications in the realm of industry, such as dyeing, printing, photography, water purification, smoke prevention, ore flotation, sewage disposal and soil preparation, paints, varnishes and lacquers, plastics, adhesives, and innumerable other operations and materials. (See **Adsorption.**) (R.K.S.)

COLLUM. 1. The dorsal plate of the first body segment in the millipedes (**Diplopoda**). 2. Any neck-like part or structure. (A.W.L.)

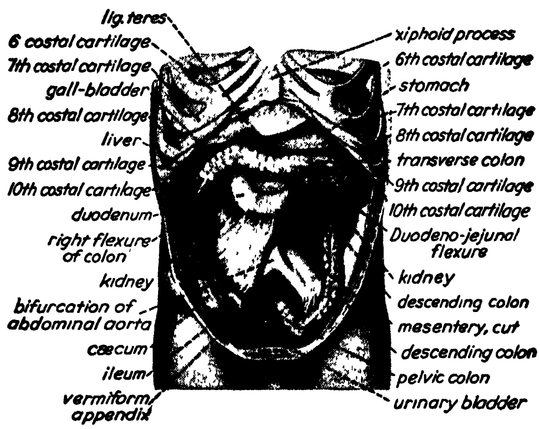
COLOB. Mammalia, Primates. *Colobus.* African thumbless **monkeys** of several species. (A.W.L.)

COLOCOLLO. Mammalia, Carnivora. A small cat of northern South America. It is light gray marked with black. (A.W.L.)

COLOCYNTH. **Citrullus colocynthus. Gourd Family.**

COLOGARITHMS. **Logarithms.**

COLON. The large intestine, which extends from the cecum to the rectum. It is divided into several parts, although the colon forms a continuous hollow muscular



The abdominal viscera after the removal of the jejunum and ileum. (*Cunningham, Textbook of Anatomy, Oxford Press.*)

tube. The ascending colon extends from the lower right side of the abdomen at the termination of the small intestine, upward to the under surface of the liver, where it turns to the left and runs across the abdomen to the lower border of the spleen as the transverse colon. Beneath the spleen it bends downward, descending along the left side of the abdomen as the descending colon. As it enters the pelvis the colon makes a double curve, similar to the letter S. This portion is known as the sigmoid colon. The end of the sigmoid colon terminates in the rectum.

The functions of the colon are (1) final absorption of the products of digestion, (2) absorption of fluid from the feces so that this material becomes semi-solid, (3) removal of the fecal waste products into the rectum.

The principal diseases of the large intestine are **cancer, tuberculosis, diverticulitis, polyp** formation, and **colitis.** (R.S.M., D.M.H.)

COLONY. A group of individuals of the same species living together for mutual benefit. They may be structurally united or separate and may be alike in form or of different types suited for various functions. (A.W.L.)

COLOR. This vast subject is complicated by the distinction between the physical basis of colors and the sensations produced by them; and still further by a somewhat confused and unsettled vocabulary.

If one looks at two surfaces of the same size and shape, equally illuminated, and at the same distance, his only means of distinguishing them is by what is called their "color." To a physicist, the color means the **spectral energy distribution** of the light emitted or reflected by the surface. One may, however, specify it more simply, though less accurately, in terms of a limited number of variables employed in color measurement or colorimetry.

The practical standard "white" light is direct noon sunlight. A "perfectly white" surface would reflect white

light completely without any alteration. No such surface exists. Even snow does not reflect white completely, though it does reflect all visible wavelengths in the same proportion. Its color is one of the "grays" or achromatic colors, of very high "brilliance"; while that of a lead-pencil mark is a much feebler achromatic color. A "black" surface would reflect no light at all (see **Black Body**). Most colors, however, are chromatic, that is, they exhibit "hue," because their spectral energy distribution differs so much from that of white or gray that they look "reddish," "bluish," etc. Some colors of the same hue are more "brilliant" than others. Just as snow is of a more brilliant gray than graphite, so bright red is more brilliant than dark red. Further, some colors have greater purity or "saturation" than others; that is, they have more pronounced hue, or are more chromatic, and therefore differ more from a gray of the same brilliance. Thus foliage looks "greener" when freshly washed than when dusty. A chromatic color having little hue but high brilliance is a "tint," e.g., pink; while one of little hue and low brilliance, like brown, is a "shade."

We must now recognize the fact that the same color sensation can be produced by entirely different physical stimuli. Tests of a large number of observers with the spectrometer indicate that, according to the average judgment, the common names of pure spectral hues should be applied to the several wavelength ranges approximately as follows:

	Angstroms		Angstroms
Violet	3900 to 4550	Yellow	5770 to 5970
Blue	4550 to 4920	Orange	5970 to 6220
Green	4920 to 5770	Red	6220 to 7700

But the sensations produced by any of these, or by any of their tints, shades, or mixtures, can also be produced in a variety of other ways. For example, red and green light may be mixed to produce a good imitation of spectral yellow light, though no yellow wavelengths are present in the mixture.

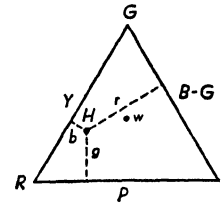
According to the Young-Helmholtz theory, the human vision has three separate color sensations, each capable of stimulation in various degrees. It is thought that, if stimulated separately, they would prove to be the sensations produced by red, blue, and green light, respectively. But they always act together, and every color sensation is the effect of their joint stimulation in some definite proportion. A result of this is that any color can be successfully imitated by adding together red, blue, and green light with suitable relative intensities. These are therefore called "additive primaries." If added in equal intensities, they produce a sensation of white. White may, however, be produced also by adding in suitable proportions various pairs of pure spectral hues, which are "complementary" to each other; thus:

Angstroms	Angstroms
6562 and 4921	5671 and 4645
6077 and 4897	5644 and 4618
5853 and 4854	5636 and 4330
5739 and 4821	

(The third pair, for example, is a certain yellow and a certain blue.)

Color sensations are also commonly produced by removing certain components from white light, as by the use of filters. Pigments such as paint and colored inks act in this way, being selectively reflective. The complementary hues of the three additive primaries are the "subtractive primaries" blue-green (for red), yellow (for blue), and purple (for green).

Maxwell devised an ingenious graphical scheme, called the "color triangle," for representing mixtures of colored lights (not pigments). The three additive primaries red, blue, green, are at the vertices of an equilateral triangle, with their complementary subtractives blue-green, yellow, purple on the sides opposite. Each altitude, as *PG*, is taken as 100%. Any hue is represented by a point *H*, whose distances r, b, g, from the three sides represent the percentages of the three primaries *R*, *B*, *G* which must be added to imitate it $(r + b + g = 100)$. Thus

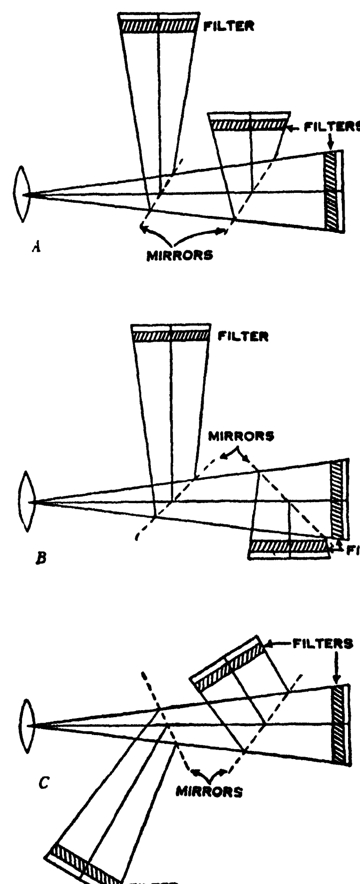


Color triangle.

for the point *H* in the figure, $r = 60$, $b = 10$, $g = 30$, giving a reddish-yellow sensation. The point *W*, at the center of the triangle, corresponds to the sensation of white. (L.D.W.)

COLOR BLINDNESS. Vision.

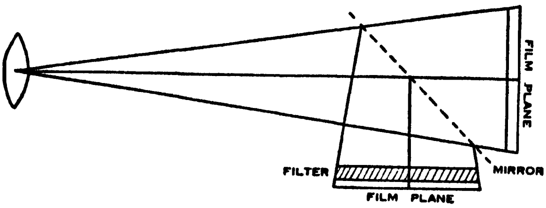
COLOR CAMERAS. Cameras designed to take color separation negatives simultaneously from the subject. Any camera used in normal black and white photography may be used to take a set of color separation negatives, but the time necessary to change filters and emulsions rules out all but inanimate subjects. Certain subjects can be satisfactorily photographed by means of a repeating back adapted to an ordinary camera. Such a mechanical device shifts filters and emulsions rapidly enough so that the total exposure time lapse is only a few sec-



Double-mirror color cameras. (The mirrors shown are partially reflecting-transmitting.) (*Neblette's Photography.*)

onds. Whenever any movement is likely to be encountered, however, a color camera is necessary.

A color camera divides the light coming from the subject at any time into two or more beams which may be simultaneously recorded on different photographic emulsions. The optical and beam-splitting devices that are currently in use consist of a single lens followed by one or two partially reflecting mirrors, or a partially reflecting prism of glass. (See Figs.) With a double-mirror

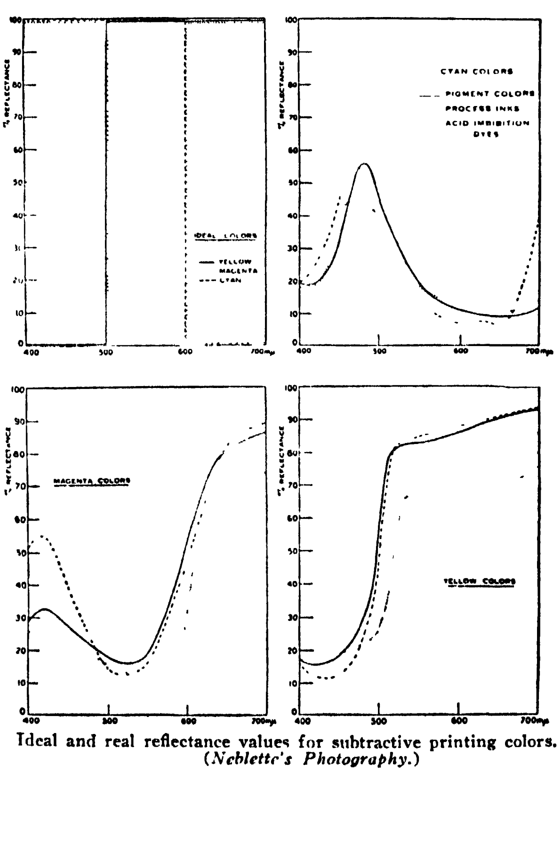


Single-mirror color camera using bipack emulsion. (*Neblette's Photography.*)

camera three appropriate emulsions and color filters yield the three-color separation negatives. With a single-mirror camera a **bipack** must be used to record two of the color records while the third is recorded on a single emulsion. A slight amount of diffusion is obtained with the latter system because of the light passing through the front emulsion of the bipack before reaching the second film exposed at that aperture.

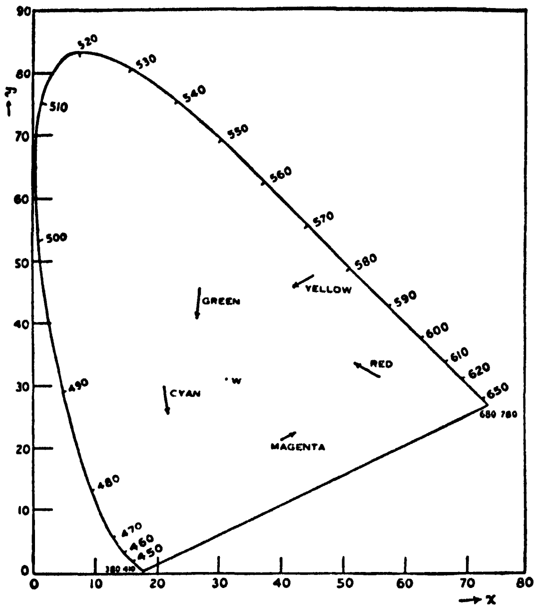
Cameras of the above types have enjoyed considerable popularity among illustrative color photographers because of the color accuracy obtainable in color prints made from direct color separation negatives. Such cameras are often termed "one-shot cameras." (H.C.C.)

COLOR CORRECTION. The steps taken in improving the reproduction in a color photograph. Color correction, or masking, is necessary if accurate color reproduction is desired because the colorants used in subtractive color processes do not fulfill the theoretical require-



Ideal and real reflectance values for subtractive printing colors. (*Neblette's Photography.*)

ments. All known cyan dyes, inks, or pigments, for example, are rather poor transmitters of blue and green light, the colors to which they should be completely



Five colors (dots) and their reproductions (arrow heads) plotted on a chromaticity diagram. (*Neblette's Photography.*)

transparent. In a similar manner most magenta colorants only transmit about 50% of the incident blue light. The use of such colorants leads to color reproduction shifts that may be generalized as reds, magentas and yellows reproduced too light; cyans, greens and blues reproduced too dark. Reds and magentas shift toward yellow; cyans and greens reproduce as somewhat colder hues. With these colorants it is also difficult to obtain a satisfactory scale of neutrals and the use of a supplementary black-printer image is often necessary.

Masking, or color correction, may be carried out photographically by combining with a given negative, or positive color record, a positive or negative which is a record of another color. It is common practice, for example, to apply to the green-record separation negative a positive mask which has been obtained from the red-record separation negative. This positive mask, of relatively low contrast, prevents magenta from printing in those areas of the reproduction that contain cyan, thus resulting in brighter cyans, blues and greens. There have been a great many systems of masking used in commercial photography but they usually involve a positive made from the red record used as a mask on the magenta printer and a positive mask made from the unmasked magenta printer used in correcting the yellow printer. The relative contrasts of negatives and masks determines the extent of the correction for each printer. Masking of this type directly on the color separation negatives greatly improves the color accuracy obtainable in a reproduction from a given set of subtractive colorants.

When it is desirable to make a reproduction directly from a positive or negative **color transparency** by photographing it and printing, a somewhat different form of color correction becomes necessary. Because of the incorrect absorptions of most subtractive colorants, the recording of a color transparency by a green filter and panchromatic emulsion, for example, yields an image not only of the transparency's magenta dye layer but also an image of the cyan dye layer. Since the magenta layer in the transparency resulted from the original green-record negative obtained when the transparency was made, this is the only image desired when photograph-

ing the transparency. The recording of the unwanted cyan image may be avoided by combining with the transparency before it is rephotographed a negative or positive cyan or silver image that will partially or completely neutralize the positive or negative cyan dye image. Then a green filter separation may be obtained of the transparency's magenta dye layer without interference from the cyan image. Such masks may be made separately and combined with the transparency, or they may be formed during the processing of the transparency in which case they are part of the integral tripack. (H.C.C.)

COLOR DEVELOPMENT. Color development, also known as chromogenic development, or dye coupling, is a process which involves the conversion of a latent image into metallic silver and the deposition of a dye in contact with the silver image.

The silver image serves to localize, or fix, the position of the dyestuff. Since the amount of dye produced is proportional to the metallic silver, the amount of dye formed in any area will be proportional to the intensity of the exposing light. Removal of silver by reduction or solvent action leaves the dye image in the emulsion.

Color development is possible because a number of dye intermediates also function as developing agents. Color development may take place in two ways. The oxidized developing agent resulting from the reduction of silver halide may combine with a portion of the unoxidized developing agent to form a dye. This method is known as primary color development. Developing agents, like pyrogallol, catechol, methoxyalphanaphthol, hydroxycoerulignon, indoxyl and thioindoxyl, show this capacity. In practice this method has not been very successful because the images formed are relatively unstable, the highlights are usually stained, and the range of color is limited.

In the second method, another dye intermediate, known as the coupler, is added to the developer. The dye forms when the added dye intermediate couples, or condenses, with the oxidized developing agent. The term coupler is applied to the second dye intermediate used. Phenols, aromatic amines, substituted methines, and azomethines having strong polar groups are satisfactory for dye coupling. This process, using two dye intermediates for dye formation, is termed secondary color development. Among the dyes used for secondary color development are: the indophenols formed by the reactions of para-aminophenol and a phenol; the indoanalines, by reaction of a paraphenylenediamine and a phenol; the indiamines with a phenylenediamine and an amine; the indothiophenols by paraphenylenediamine and a thiophenol; and the azomethines from the reaction of a para-aminophenol or a phenylenediamine with a methine containing active or strong polar groups. Secondary color development has been used successfully for the production of prints in color and for color transparencies with integral tripack processes because a wide variety of colors is possible by using different couplers with a limited number of developing agents or with a single developing agent. Couplers may either be incorporated in emulsions or added during processing.

The formation of a dye image by color development may take place simultaneously with the reduction of the silver image or in two steps. A molecule of the developing agent becoming oxidized as a result of the reduction of the silver halide molecule, and the coupling of the oxidized developing agent with the coupler which requires the reduction of these silver halide molecules. In either method four atoms of silver are reduced for every molecule of dye formed.

Latent images, bleached silver images, or chromate images, may be used for the production of dye images by color development. (See **Chromogenic Developing Agents, Chromogenic Couplers.**) (S.M.T.)

COLOR IMAGE FORMATION. Processes of color photography using an additive synthesis usually obtain their color images by means of neutral silver images and the placement of color filters in the light beams. Subtractive synthesis, however, requires that the image itself be colored, and the many ways of forming these images, both chemically and physically, have led to the numerous photographic **subtractive color processes** now in existence.

Three-color subtractive processes use the colorants cyan, magenta and yellow in printing from the red, green and blue analysis separation records. The exact hues of cyan, magenta and yellow used in the various processes vary widely, although the ideals would be optically equivalent to the colors used in an additive synthesis. The printing procedure for all subtractive color processes has as its goal the registration of the three colorant images one above the other. This may be performed automatically as in the integral tripack processes or they may be obtained separately and superimposed as in the various separable processes such as **carbro.**

A classification of photographic subtractive processes shows six distinct types of colorant image formation. The lines of demarcation between the various methods cannot be drawn too clearly since many commercial processes make use of more than one method of colorant image formation. In the accompanying table the processes are listed together with the usual colorant material employed with each type of image formation. (See **Additive Color Process, Bipacks and Tripacks.**)

SUBTRACTIVE PRINTING PROCESSES

Process	*Medium*
I. Toning Processes	
A. Metallic Toning	Colored Metallic Salts
B. Dye Toning or Mordanting	Dyes, usually basic
II. Gelatin-Relief Processes	
A. Tanning Development	Dyes or Pigments
B. Dichromated Colloids, Hardening Brought About by:	
1. Light	Pigments
2. Silver	
a. Carbro	Pigments
b. Hardening Bleaching	Dyes
c. Dyebro	Dyes
C. Etching	Dyes
III. Differentially Hardened Colloids —relief formation not essential	
A. Differential Staining	Dyes
B. Differential Water Absorption	Inks
IV. Dye Coupling	Dyes
V. Dye Destruction	Dyes
VI. Dye Bleaching	Dyes

(H.C.C.)

COLOR INDEX. The human eye is more sensitive to red light than is the photographic plate, while the latter is the more sensitive to the green and blue regions of the **spectrum** than is the eye. Accordingly, if we have a blue and a red star of the same apparent brightness, or in other words, the same visual **magnitude**, the blue star will make a much stronger image on the photographic plate than will the red. Hence, the scale of magnitudes determined from a sequence of stars of different colors, when determined photographically, will be different from that determined visually. The difference between the photographic and visual magnitude of any given star is known as the color index of the star. The algebraic sign of the color index is determined from the relation: photographic magnitude − visual magnitude = color index.

Since the **spectral type** of a star is also a function of the color of the star, we should expect to find a definite relationship between color index and spectral type. The "zero point" of the scale of photographic magnitudes has been defined in such a manner that the color index is zero for an A0 type star between 5.5 and 6.5 magni-

tudes. For the other spectral classes the values of the color index are approximately:

B	A	F	G	K	M
−0.24	0.00	+0.28	+0.56	+1.00	+1.35

In accordance with the theory of **black-body radiation**, the apparent color of a radiating gas should be a function of the temperature of the gas and color index may be used as an approximate method for the determination of the temperatures of the stars. (W.K.G.)

COLOR NEGATIVE. A photographic image in which not only the brightness of the various parts of the scene is reversed, but the color of each area is complementary to that in the original scene. (H.C.C.)

COLOR PHOTOGRAPHY. The creation, by photographic means, of sensations in the brain of the observer approximating as closely as possible the sensations he would have experienced in oberving the colored subject directly.

The steps necessary to form the sensation may best be classed as analysis and synthesis. The proces of analysis involves the recording on two or more photographic emulsions of the proportions of the visible spectrum reflected or emitted by the subject. For example, a color-sensitive emulsion exposed behind an orange-red filter will record the areas of the subject photographed which reflect or emit red light, these areas being shown on the developed negative as silver densities. The actual densities will bear a definite relation to the amount of orange-red light from each subject area. Photographic density thus becomes a quantitative measure of the orange-red light present in the subject. If the same procedure is employed with another color-sensitive emulsion but this time using a blue-green filter, a two-color analysis of the original subject will have been obtained in the form of two photographic negatives, one a "red-orange record," the other a "blue-green record." If three negatives had been made using red, green and blue filters, a three-color analysis would have resulted.

The synthesis, or recombination, of the photographic analysis may take many different physical or chemical forms, depending on whether the synthesis is to be additive or subtractive and on the method of image formation. In its simplest additive form, the synthesis consists of the simultaneous projection, in register, from two projectors, of the black and white positive images made from the analysis negatives. Since densities in the red-orange record indicate the presence of red-orange in the subject, a positive or lantern-slide image is reversed in the sense that the silver densities now indicate absence of red-orange while the clear areas of the positive indicate the presence of red-orange. A similar situation exists for a positive made from the negative recording the blue-green in the subject.

If a red-orange filter is inserted in the light beam of the projector containing the first positive, only red-orange light will reach the screen. The position and quantity of this light is controlled by the silver positive. Image areas that correspond to those areas of the subject completely lacking in orange-red will be dark, while the more orange-red there was in the subject the lighter the positive will be, thus transmitting more orange-red onto the screen. If the second positive is projected onto the screen in register with the first by means of another projector employing a blue-green filter, the additive synthesis will be complete. A three-color additive synthesis may be carried out in a similar manner with three positives and projectors equipped with red, green and blue filters.

The observer viewing the image of such a synthesis receives a complex stimulus through the medium of his eye The similarity of his sensation to that obtained when viewing the subject directly is indicative of the accuracy of the photographic color reproduction.

The majority of color photographs today are made by some form of subtractive synthesis. This differs from an additive synthesis where light is added to light on a screen to form the final color image. In the subtractive synthesis colorants are used to subtract from white light the desired color; i.e., a yellow dye (colorant) is used to subtract blue light from white. An ideal subtractive synthesis gives the same sensation as that obtained from the additive synthesis. (See **Additive Color Process, Subtractive Color Process.**) (H.C.C.)

COLOR TRANSPARENCY. A color photograph made for viewing by transmitted light. As the light only passes through the colorants of a transparency once, their contrast is about double that necessary in a print on an opaque support which is viewed by reflection. The colorant images may either be the components of an integral tripack or may be simply three colorants superimposed after their preparation by subtractive synthesis. (H.C.C.)

COLORADO POTATO BEETLE. Insecta, Coleoptera. A leaf-eating **beetle**, *Leptinotarsa decemlineata,* native to the western United States Originally it fed on a native plant but about the middle of the nineteenth century it became troublesome in potato fields and rapidly spread across the country. Both larva and adult eat the leaves of potato plants. They can be checked by the use of Paris green or lead arsenate used as a spray. (A.W.L.)

COLORATION. The coloration of animals embraces both the colors that appear in their bodies and the patterns in which they are arranged. In many species color appears to be incidental but in others coloration has an important bearing on the life of the individual.

Colors are due in some cases to the presence of compounds which are important for other reasons. The blood of insects, for example, may be green, that of certain mollusks blue, and that of the vertebrates and annelid worms red because of their chemical composition (see **Protein**), but these colors have no important bearing on individual life. The black pigment found in eyes is a protection against random light rays but any impervious layer would be as effective; black color is unimportant in itself.

In many animals colors of this kind are supplemented by special pigments located in the superficial layers of tissue and in the vestiture, such as hair, feathers, and scales. The surface of the integument in insects is often formed so that it breaks up light rays and reflects only a portion of them. The colors produced in this way are called physical colors and are usually metallic or glassy. All of these colors, whether physical or pigmental, are often arranged in intricate patterns characteristic of the species. In this arrangement details may be observed in some animals which seem to have definite value in relating the individual to its environment.

The white tail patch found in some **deer** and **rabbits** has been interpreted as a signal mark. It may serve for ready recognition in poor light and may catch the attention of other members of a group when danger is near.

Warning colors are exemplified by the brilliant red and yellow of the **coral snakes.** Poisonous or distasteful animals are usually avoided as food and conspicuous appearance makes it all the easier for other animals to see and avoid them.

Concealing colors render the animal less conspicuous in its normal environment, and are essentially the same in the hunter and in the hunted. The white winter coats of the **prairie hare** and of the **weasel** are equally inconspicuous against the snow, but the one animal is helped to escape its enemies and the other to catch its prey by this means. Concealing colors may also be in patterns. The black and tawny stripes of the **tiger,** for

example, are said to conceal it admirably in tall grasses lighted by the sun, where vertical shadows are conspicuous. This aspect of coloration, however, merges with protective **mimicry**, and in mimicry physical form is involved as well as coloration. (A.W.L.)

COLORS. For list of approved food, drug and cosmetic colors see reference in **Dyes and Dyeing Textile Fibers.**

COLOR-SENSITIZING DYES. The color-sensitizing dyes are those which added to the silver halide emulsions cause them to become more sensitive not only to the ordinary range of silver halides in gelatin but increase the spectral range, even in the infra-red or long-wave part of the spectrum. The dyes used are generally, selective with respect to a particular range, hence, it is common practice to use more than one dye for general photography. These dyes not only increase the spectral range but permit the photographer to obtain better results where only short-time exposures are possible. The following examples may serve as an illustration.

Corallin is the dye which was originally used to prevent halation in silver halide-collodion emulsions, and accidentally the general principle of sensitization of photographic emulsions was discovered.

The tetraiodo derivatives of the dye, selena and telluraxanthones, are said to be good sensitizers for the spectral range of 520–610 $m\mu$. It is doubtful, however, if they can be used in place of the simple cyanines or simple merocyanines.

The cyanines are probably the most important sensitizing dyes, although the merocyanines have come into considerable prominence in the last 10 years. The cyanines comprise the largest number of satisfactory sensitizers used in present-day emulsions.

Very good sensitizers for the yellow are found in the benzooxazoles and also benzthiazoles. Kryptocyanine is an example of the quinoline derivatives and is important, since its introduction opened up the field of extreme red and near infra-red sensitivity. It does not sensitize beyond 800 $m\mu$.

The dicarbocyanines or pentamethines have a maximum absorption at about 670–700 $m\mu$. The tricarbocyanines or heptamethines are sensitizers for the range 650–1050 $m\mu$. The tetra and pentacarbocyanines have been prepared and contain a linking chain of 9 and 11 carbon atoms respectively. Only a few of these long-chain dyes are of practical value for the extreme infra-red. (RALPH BRADEN, ROCHESTER INSTITUTE OF TECHNOLOGY.)

COLOR-SEPARATION NEGATIVES. Photographic negatives which record the relative intensities of the primary colors used in the analysis necessary to reproduce a subject by means of color photography. In three-color photography, for example, the separation negatives are records, in terms of silver densities, of the amounts of red, green and blue light received at the camera from the subject.

A set of color-separation negatives may be prepared by photographing the subject three times on separate color-sensitive emulsions so that each is a record of one of the primary colors. A panchromatic emulsion is generally employed with a set of tricolor filters, the colors of the primaries. It is only necessary, however, to obtain the color records on separate negatives so it is also possible to use for each record any combination of color filter and emulsion sensitivity that will record one of the primary colors. A set of color-separation negatives may be made by exposing (1) each one in turn in a camera, (2) by the use of a color camera which will expose them simultaneously, or (3) in a tripack.

It is common practice to balance a set of color-separation negatives, by altering the exposure and development times, so that a **gray scale** will be recorded equally on each negative. The particular densities desired are dependent on the method of color synthesis to be employed. (H.C.C.)

COLOSTRUM. The fluid secreted by the mother's breasts a few days before and after the birth of the child, before the secretion of true milk begins. It is a thin watery fluid containing considerable albumin. (D.M.H.)

COLUMBIFORMES. The order of birds (**Aves**) containing the **pigeons and doves.** (A.W.L.)

COLUMBINE. Buttercup Family.

COLUMBITE. A mineral oxide of iron, manganese, columbium and tantalum. Crystallizes in the orthorhombic system. Hardness, 6; specific gravity, 5.20±; color, red to brown. (R.M.F.)

COLUMBIUM or **NIOBIUM.** Symbol: Cb. Atomic number: 41. Atomic weight: 92.91. Density: 8.4. Melting point: 1950° C. No isotope, but of single atomic form: 93.

Columbium is a slightly bluish metal; ductile, malleable, and when polished resembles platinum; burns upon being heated in air; insoluble in **hydrochloric** or **nitric acid,** but soluble in **hydrofluoric acid** or a mixture of hydrofluoric and nitric acids. Discovered by Hatchett in 1801.

Columbium occurs, usually with tantalum, in columbite ($Fe(CbO_3)_2$, 80% Cb_2O_5), pyrochlore (50% Cb_2O_5), samarskite (50% Cb_2O_5), chiefly found in western Australia, and South Dakota. Recovered along with **tantalum** by fusion with **potassium** bisulfate, and obtained in the residue after subsequent extraction with water. Columbium and tantalum are separated by fractional crystallization of the potassium fluorides, columbium concentrating in the mother liquor and tantalum in the crystals. Chemically related to **vanadium** and **tantalum.** Columbium is used (1) in steel, especially *stainless steel,* to stabilize the carbon present (as carbide), and (2) for columbium carbide (see **Abrasives**) for dies and cutting tools. Ferro-columbium alloy is used as a source of columbium for addition to corrosion-resistant steel.

Fluoride: Columbium potassium fluoride ($K_2CbF_6 \cdot H_2O$).

Chlorides: Columbium trichloride ($CbCl_3$); columbium oxychloride ($CbOCl_3$), white solid; columbium pentachloride ($CbCl_5$), yellow crystals, melting point 194° C., boiling point 240° C.

Columbates: Columbium of valence plus 5.

Oxides: Columbium monoxide (CbO) (sometimes called dioxide, Cb_2O_2); columbium dioxide (CbO_2) (sometimes called tetroxide, Cb_2O_4); columbium pentoxide (Cb_2O_5). (R.K.S.)

COLUMELLA. 1. The axis of the spiral shell of a snail. 2. A bone in the middle ear of amphibians, reptiles and birds. (A.W.L.)

COLUMN. A slender structural compression member, standing vertically, is a column. The ratio of the length of the column to the least **radius of gyration** of its cross-section is called the slenderness ratio. This ratio affords a means of classifying columns. A short steel column is one whose slenderness ratio does not exceed 50; an intermediate length steel column has a slenderness ratio ranging from 50 to about 200, while a long steel column may be assumed as one having a slenderness ratio greater than 200. A short concrete column is one having a ratio of unsupported length to least dimension of the cross-section not greater than 10. If the ratio is greater than 10 it is a long column. Timber columns may be classed as short columns if the ratio of the length to least dimension of the cross-section is equal to

or less than 10. The dividing line between the intermediate and long timber columns cannot be readily evaluated. One way of defining the lower limit of long timber columns would be to set it as the smallest value of the ratio of length to least cross-sectional dimension that would just exceed a certain constant K of the material. Since K depends upon the **modulus of elasticity** and the allowable compressive **stress** parallel to the grain it can be seen that this arbitrary limit would vary with the species of timber. The value K is given in most structural handbooks.

If the load on a column is applied through the center of gravity of its cross-section it is called an axial **load.** A load at any other point in the cross-section is known as an eccentric load. A short column under the action of an axial load will fail by direct **compression** but a long column loaded in the same manner will fail by buckling (bending), the buckling effect being so large that the effect of the direct load may be neglected. The intermediate length column will fail by a combination of direct stress and bending.

In the middle of the 18th century a mathematician named Euler derived a formula which gives the maximum axial load that a long, slender ideal column can carry without buckling. An ideal column is one which is perfectly straight, homogeneous and free from initial stress. This maximum load, sometimes called the critical load, causes the column to be in a state of unstable equilibrium, that is, any increase in the loads or the introduction of the slightest lateral force will cause the column to fail by buckling. The Euler formula for columns is given below.

$$P = \frac{K\pi^2 EI}{l^2}$$

in which P = Maximum or critical load.
E = Modulus of elasticity.
I = Moment of inertia of cross-sectional area.
l = Unsupported length of column.
K = A constant whose value depends upon the conditions of end support of the column. For both ends free to turn $K = 1$; for both ends fixed, $K = 4$; for one end free to turn and the other end fixed $K = 2$ approximately, and for one end fixed and the other end free to move laterally $K = \frac{1}{4}$

Examination of this formula reveals the following interesting facts with regard to the bearing power of columns. First, that elasticity and not compressive strength of the materials of the column determines the critical load. Secondly, the critical load is directly proportional to the moment of inertia of the cross-section. The strength of a column may therefore be increased by distributing the material so as to increase the moment of inertia. This can be done without increasing the weight of the column by distributing the material as far from the principal axes of the transverse section as is possible consistent with keeping the material thick enough to prevent local buckling. This bears out the well-known fact that a tubular section is much superior to a solid section for column service. Another bit of information that may be gleaned from this equation is the effect of length upon critical load. For a given size column doubling the unsupported length quarters the allowable load. The restraint offered by the end connections of a column also affects the critical load. If the connections are perfectly rigid, the critical load will be four times that for a similar column where there is no resistance to rotation (hinged at the ends).

Since the moment of inertia of a surface is its area multiplied by the square of a length called the **radius of gyration,** the above formula may be rearranged as follows. Using the **Euler** formula for hinged ends, and substituting Ar^2 for I the following formula results:

$$\frac{P}{A} = \frac{\pi^2 E}{\left(\frac{l}{r}\right)^2}$$

$\frac{P}{A}$ is the allowable unit stress of the column, and the quantity $\frac{l}{r}$ is known as the slenderness ratio. This ratio is an important function of a column, since columns having a slenderness ratio below certain definite values (determined from the material of the column) cannot be considered to be in the Euler range, as the compressive stress may reach the yield point before failure by bending can occur.

Since the structural column is generally an intermediate length column and it is impossible to obtain an ideal column, the Euler formula has little practical value for ordinary design. Consequently, various empirical column formulae have been developed to agree with test data, all of which embody the slenderness ratio.

In architecture, the column is a round vertical structural member which may, however, sometimes be more ornamental than utilitarian. As such columns are frequently made of inelastic material, the above analyses of critical loads would not necessarily apply to all architectural columns. (C.W.C., F.T.M.)

COLUMN RESTRAINT. Column.

COLUMNAR STRUCTURE. Prismatic columns which develop in **basic** lavas, due to the stress-strain relationships set up by rapid chilling. A relatively frequent phenomenon in basalt flows, such as those of the Giants' Causeway, Ireland. (R.M.F.)

COLY, COLIES. Aves, Cuculiformes. *Colius.* African birds (**Aves**) of several species, also known as mouse birds. They have four toes, directed forward. The beak is strong and slightly curved, the head crested, and the tail long. (A.W.L.)

COLYMBIFORMES. An order of swimming and diving birds (**Aves**) with lobed toes. The **grebes.** (A.W.L.)

COMA. A state of complete unconsciousness from which the individual cannot be aroused even by powerful stimuli. It occurs following severe head injury, in cerebro-vascular accidents (**apoplexy**), in acute alcoholism, in uncontrolled **diabetes** (diabetic **acidosis**), in terminal **uremia,** and just before death in many diseases. Coma also follows overdosage with certain drugs, particularly central nervous system depressants like **morphine, barbital** derivatives, and **chloral hydrate.** (D.M.H.)

COMANCHEAN. Cretaceous.

COMB RIDGE. Cirque.

COMBINATION DIE. Die Casting, Press Work.

COMBINATION PRINCIPLE. The principle, first recognized by Ritz, that the many frequencies exhibited by the spectrum of a substance can be regarded as differences between a comparatively few terms characteristic of the substance, taken two at a time in their various possible **combinations.** Ritz's statement was quite empirical, but we now understand that these terms correspond to the different possible energy states of the atom or molecule, and that the much more numerous spectral frequencies correspond to "jumps" or transitions from one state to another with consequent release or absorption of radiation quanta. For example, if an atom had twenty possible energy states or "levels," the number

of possible transitions releasing energy would be theoretically $20 \times 19/2! = 190$.

It does not follow, however, that all of the corresponding frequencies are actually found in the spectrum; some may be for some unknown reason apparently "forbidden," or of such rare occurrence as not to produce observable spectrum lines. When the principle is applied to certain **molecular spectra**, slight discrepancies are found which may be explained by assuming that some of the energy levels are not single but are close doubles. Such a discrepancy is known as a "combination defect." (See **Quantum Theory.**) (L.D.W.)

COMBINATION SET. **Measurement.**

COMBINATION TONES. No acoustic or electroacoustic communication system or receiving apparatus is free from **distortion.** By this is meant that the wave form of the acoustic output is not strictly similar to that of the acoustic input, so that the quality of the sound is somewhat altered. (See **Musical Sounds.**) The human ear is no exception to this rule. The fact is that the vibrations received in the cochlea, with the consequent sensations, do not accurately represent the periodic variations of air pressure in the auditory canal, and that we hear subjectively sounds that have no external physical existence. The most important aspect of this auditory distortion is the fact that when two pure musical tones are sounded, which are not of too nearly the same pitch, many persons can distinctly hear other tones in addition to the two actual ones. These subjective sensations are called combination tones, from the fact that they correspond in pitch to tones having frequencies equal to the difference, to the sum, or to other simple combinations of the two actual frequencies.

By far the most conspicuous of these subjective tones is the difference tone. Thus if one plays on a piano the two notes e (333) and c (528), many listeners hear, in addition to these, a note in the key of g (195), in the octave below, which is equal to $528 - 333$. It was formerly supposed that the difference tone was the effect of **beats,** but Helmholtz detected sum tones and showed, further, that the difference tone sensation is too loud to be attributed to beats.

The cause of distortion in the case of the ear is believed to lie in the fact that the ear drum, or tympanic membrane, does not vibrate symmetrically. Mathematical analysis shows that if the tympanum moves farther inward than outward from its normal position during vibration, the waves passed on from it to the cochlea will contain other frequencies than those making up the original sound, and that in the case of a sound composed of two pure tones of frequencies n_1 and n_2, there will arise also the frequencies $n_1 - n_2$, $n_1 + n_2$, $2(n_1 - n_2)$, etc.

The existence of difference tones is of value in electroacoustic apparatus such as the telephone and amplifier systems, and also in the pipe organ, the deficiencies of which in the lower frequency range are partially offset by the low difference tones that the listener thinks he hears. There is evidence that the "striking note" of certain chime bells is really a difference tone and does not exist among the partials of the complex sounds of these bells. The occurrence of combination tones can hardly fail to be of importance also in the effect on the ear of chords in musical harmony. (L.D.W.)

COMBINATIONS. Each of the groups or selections which can be made by taking some or all of a set of things, without regard to order of arrangement, is called a combination.

The number of combinations of n things taken r at a time is denoted by ${}_nC_r$ or $C_{n,\,r}$ or $C(n, r)$.

The number of combinations of n different things taken r at a time is

$${}_nC_r = \frac{n(n-1)(n-2)\cdots(n-r+1)}{r!} = \frac{n!}{r!(n-r)!}.$$

Also,

$${}_nC_r = {}_nC_{n-r}.$$

The total number of combinations is:

$${}_nC_1 + {}_nC_2 + {}_nC_3 + \cdots + {}_nC_n = 2^n - 1;$$

that is, the total number of combinations of n things taken $1, 2, 3, \cdots, n$ at a time is $2^n - 1$.

Combinations are closely related to **permutations.** Each combination containing r elements can yield $r!$ permutations by rearranging its elements in different orders. Hence, ${}_nP_r = r! \cdot {}_nC_r$. (L.L.S.)

COMBINED STRESS. **Stress.**

COMBINING WEIGHTS, LAWS OF. The laws of combining weights are:

1. Fixed Proportions. The elements in a chemical compound are combined together in a fixed and definite proportion by weight.

2. Multiple Proportions. When two chemical compounds contain the same elements, then the fixed proportions in each are related to each other by a simple ratio. For example, in carbon dioxide 12 parts by weight of carbon element combined with 32 parts by weight of oxygen element, in carbon monoxide 12 parts by weight of carbon element combined with 16 parts by weight of oxygen element, therefore, in the two oxides the ratio of oxygen is 32:16 or 2:1 on the same carbon weight basis.

3. Reciprocal Proportions. The proportions in which two elements or radicals combine with a third element or radical are in a simple ratio to the proportions in which they combine with each other (if they combine) or with a fourth element or radical (Richter, 1792). Therefore, each element or radical has a characteristic equivalent weight. (R.K.S.)

COMBUSTIBLE. Any substance which will enter rapidly into chemical union with *oxygen,* and produce light or heat in useful quantities, is combustible. Practically all of the combustible fractions of useful commercial fuels, including solid, liquid, and gaseous fuels, are composed of carbon and hydrogen, either in the elementary or combined form (hydrocarbons). Even carbon monoxide (in water gas) and the alcohols are but oxygen compounds of carbon, and of carbon and hydrogen, respectively. Nearly 100% of natural gas or **fuel** oil is combustible. In **coal** there may sometimes be found a considerable amount of non-combustible matter, which is chiefly moisture and an aggregation of various mineral compounds known commonly as ash. Ash-free and moisture-free coal is known as combustible. (F.T.M.)

COMBUSTION. Combustion is the rapid chemical union of a **fuel** with **oxygen,** accompanied by the liberation of useful heat energy. (See **Reactions Involving Oxidation-Reduction;** and **Thermochemistry.**) When a coal is subjected to combustion conditions it first absorbs the heat necessary to bring it to the volatilization temperature. This will include both sensible heat and latent heat necessary to vaporize its moisture content. Further heating evolves the volatile hydrocarbons, leaving behind the fixed carbon and ash. It is the hydrocarbons that must be most carefully handled to insure freedom from smoke and attendant incomplete combustion. A major function of any furnace and stoker, grate, or burner installation is the proper mixing of oxygen with this evolved volatile material, and the further subjecting of the mixture to the ignition temperature, with sufficient time being given for complete combustion. The fixed carbon will then burn freely with an intense heat, and under correct conditions will be completely consumed to carbon diox-

ide. Each small piece of incandescent carbon has its surface atoms burned to carbon dioxide upon contact with an oxygen atmosphere. The piece will then be blanketed with carbon dioxide, an inert gas, unless additional air is applied in such a manner as to scrub the particles of carbon free of carbon dioxide and expose fresh surface to combustion. Stokers and grates accomplish this by permitting the motion of air past a stationary fuel bed at high velocity induced by **draft.** Pulverized coal **burners** are designed for the turbulent mixing of air and fuel, both of which are moving into the furnace about the same velocity.

The requirements for combustion are:

1. Thorough mixing of fuel and air in proportions which will insure complete combustion.
2. Exposure of fuel particles to oxygen throughout a period of time sufficient for their combustion.
3. Maintenance of the combustion zone at a temperature above that of ignition of the fuel.

The air required for combustion may be considered as composed of two parts: that which is used to supply oxygen for union with the fuel during the process of combustion; and that which is supplied in excess so that there will be a certainty of having an oxygen atom adjacent to a fuel atom when required. Combustion equations of typical fuel elements or compounds are shown in the accompanying table. The following equations illustrate how the information may be obtained. Taking the combustion of carbon to carbon dioxide for example:

Chemical reaction: $C + O_2 = CO_2$
Combining mols: 1 mol + 1 mol = 1 mol
Combining weights: 1 × 12 lbs. + 1 × 32 lbs. = 1 × 44 lbs.

Thus, each 12 lbs. of carbon require 32 lbs. of oxygen for complete combustion. Taking into consideration the fact that air has only 23.2% by weight of oxygen, a pound of oxygen is contained in $\frac{1}{.232}$ lbs. of air; consequently, in the combustion of carbon to carbon dioxide, 12 lbs. of carbon require $\frac{32}{.232}$ lbs. of air, or 1 lb. of carbon requires

$$\frac{32}{12 \times .232} = 11.5 \text{ lbs. of air, theoretically.}$$

Correspondingly, hydrogen needs 34.5 lbs. of air per lb., and sulfur 4.3 lbs. per lb. The air theoretically required to burn a pound of coal is

$$\text{Air} = 11.5C + 34.5\left(H - \frac{O}{8}\right) + 4.35S \text{ lbs. of air per lb. of coal.}$$

The symbols represent fractional proportions of the elements in the ultimate analysis. The $\left(\frac{O}{8}\right)$ correction allows for the hydrogen which is already combined and for that which will be burned with free oxygen in the fuel.

An account of the dynamic conditions surrounding furnace combustion, more air than might be indicated by the above equation will be necessary for complete combustion. The excess air is the ratio of the amount of air actually used over and above the theoretical amount to the theoretical amount. It varies from about 10% in large furnaces fired by burners to 40 or 50% in well-operated stokers, and 100% or more in hand-fired furnaces. Otto cycle engines operate on an excess of practically 0%, Diesel cycle engines may use 100% or more of excess air.

Since atmospheric air is composed of only 20.9%

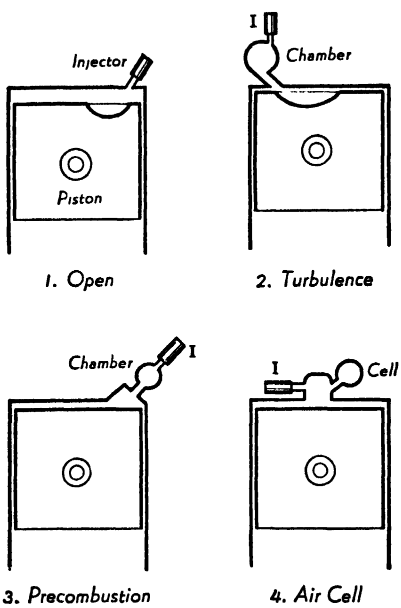
oxygen by volume, the remaining 79.1% (nitrogen chiefly, but with minute amounts of argon, carbon dioxide and other gases) is inert and merely absorbs heat, causing a loss of efficiency. From these proportions, and the fact that a cu. ft. of oxygen burns to a cu. ft. of carbon dioxide, we see that the theoretical maximum of carbon dioxide in stack gas will be 21% with perfect combustion, no excess air and no hydrogen in fuel. Actual coal-burning conditions lower this to a point at which 14% is considered to represent very good combustion. (F.T.M.)

COMBUSTION CHAMBER. An isolated region, arranged especially to promote the combustion of a fuel in it is a combustion chamber. The **furnace** is one type of combustion chamber. The space into which the piston of an internal combustion engine compresses the air, or air-fuel mixture, is called the combustion chamber. A description of engine combustion chambers should begin with a classification into those for spark ignition and those for compression ignition engines.

Spark Ignition Engines. Combustion chambers for these engines are comparatively simple. Details vary as to location of spark plugs and position of valves. As compression ratios were increased, prevention of **detonation** became a major problem. Much research has been carried out to determine in what manner detonation may be a function of combustion-chamber shape. This has resulted in various arrangements of spark-plug location, as well as special shaping of the interior curves of the cylinder head surface in order to promote turbulence, reduce length of flame travel from the spark, and secure good heat transmission from gas to cylinder head.

Compression Ignition Engines. Diesel-engine combustion chambers exhibit great differences, especially in the field of the high-speed automotive engine. The best enactment of the Diesel cycle of operations is secured at low engine speed but at the expense of heavy



Various types of Diesel combustion chambers.

construction. In the compression ignition engine only air is compressed by the piston, after which fuel must be injected into the air. The air pressure is high and a fuel jet of good atomization will have poor penetration, and consequently poor mixing with the air. The same would be true of a solid jet which, while possessing good penetration power would expose little surface and fail to obtain mixing. In a slow-speed engine a fuel jet of moderate atomization and good penetration will be granted sufficient time for complete combustion without detonation in a plain or "open" combustion chamber. It is in high-speed engines that the variations in combustion chamber design are most noticeable. These might be classified as *turbulence precombustion,* and *air-cell* combustion chambers. Such cylinder heads have auxiliary chambers or pockets incorporated for the purpose of promoting a high degree of turbulence. The fuel spray is received in both the turbulence and precombustion chamber, but incomplete combustion predominates in the latter since approximately ⅓ of the air in the combustion chamber is driven into the precombustion chamber, whereas over ¾ of it is compressed into the turbulence chamber. However, in either case the fuel is sprayed into the auxiliary chamber, whereas the main chamber receives the fuel in an air-cell type. The air cells usually contain even less of the compressed air than a precombustion chamber will. As soon as piston travel lowers combustion chamber pressure, the air-cell contents are ejected into the main chamber, creating turbulence. (F.T.M.)

COMBUSTION CONTROL, AUTOMATIC. Good combustion of fuel in a furnace, efficiently, smokelessly, and at the desired rate, is difficult to achieve by manual adjustments if the desired rate of heat liberation is subject to variation. Systems of automatic combustion control have been developed which, when installed, relieve the furnace operator of the need of making some or all of those adjustments, depending on the degree of automatic control supplied.

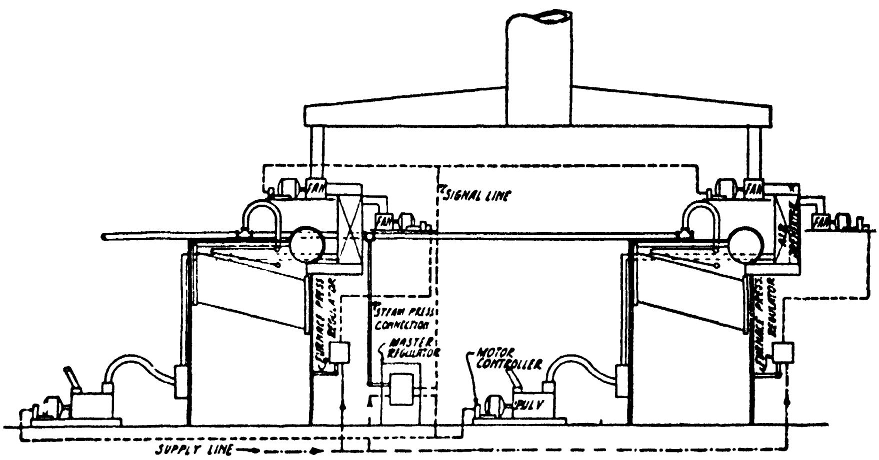
As the steam boiler furnace furnishes an example of as complex a combustion control requirement as any, it is used as an example of the application of automatic combustion control. The control consists of simultaneous and proportionate variation of fuel and air to meet the load variability and is exercised through change of fan speed, damper position, and fuel feed. In order that a complex control system be most successful, application of the control regulators is given consideration at the time of choosing the drive for fans, fuel feeders, etc. Combustion control is of special benefit in plants where the highly variable demand makes it next to impossible to maintain a uniform steam pressure manually. Furthermore the carbon dioxide can be continuously maintained at the desired value. The ideal combustion control equipment should accomplish the following objectives:

1. Divide the load equally among boilers.
2. Regulate rate of firing in accordance with load.
3. Maintain steam pressure within predetermined limits.
4. Maintain proper proportioning of fuel to air.
5. Regulate the furnace vacuum.

A simple form of control wherein steam pressure automatically adjusts the draft is applicable to the smallest plants. The damper regulator substitutes mechanical control for the frequent opening and closing of dampers by competent firemen, or for the open position often maintained by poor firemen. The rate of fuel feed and adjustment of over-fire air remains under manual control; however, this phase of combustion control can be better judged by visible indication than may air supply.

A complete combustion control system is illustrated. It is necessarily restricted in use to large installations, where initial cost and operating conditions justify the expense of completely automatic control. The steam pressure is transmitted to a master regulator which modifies the signal supply medium (shown by dot-dash) to a variable signal (shown by dash). The individual controllers upon receiving this signal act to change motor speeds, damper openings, coal feeds, etc. During the process of initial adjustment of the system the controllers have been corrected so that the signal

transmitted by the master regulator results in just the change in motor speed, damper position, etc., needed by the boiler unit at that particular rate of combustion. The signalling medium may be air under either plenum or vacuum, liquid, or electricity. The furnace pressure controller is independent of steam pressure, for a predetermined vacuum should be maintained in the furnace at all ratings. (F.T.M.)



Elements of a fully automatic control system. (*Morse's Power Plant Engineering and Design.*)

COMBUSTION JET VELOCITY. When fuels are burned in a combustion chamber, the exit of which is a well-shaped nozzle, the products of combustion attain a high jet velocity since combustion supports a chamber pressure of considerable magnitude. Like any other gas jet (see **Jet, Gas**), the velocity is a function of combustion chamber pressure. Rockets are burdened with the need of carrying an oxidizing agent as well as a fuel. The product of mass per second of the jet and its velocity is the principal factor in rocket action—the greater this product the more powerful the rocket. The total rocket weight for a shot of definite thrust and duration can be made smaller if the fuel used has a higher jet velocity.

The ideal maximum velocity for a fuel is based on the assumption that all the lower heating value is transferred into kinetic energy of the jet. A pound of hydrogen which yields up some 52,400 B.T.U. per lb. produces 9 lbs. of jet matter when completely burned with pure oxygen. Nine pounds moving at 17,100 ft. per sec. represents kinetic energy equivalent to this heat; consequently, that is the ideal maximum velocity for hydrogen. Other fuels have jet velocities as follows:

Fuel	Maximum Exhaust Velocity, Ft. per Sec.
Acetylene	15,900
Gasoline	14,500
Kerosene	14,500
Alcohol	13,300
Gunpowder	7,000
Smokeless powder	9,600

(F.T.M.)

COMET. Comets are objects which are moving in space under the influence of the sun's gravitational field and which occasionally come close enough to the earth to be observed. The name comes from the descriptive Latin phrase stellae comatae (hairy stars), and aptly describes the appearance of this class of celestial objects. Their appearance is so different from all other objects in the night sky that they have always attracted a great deal of attention. They were formerly regarded with superstitious awe and supposed to portend all sorts of calamities to the earth and its inhabitants. For these reasons the appearance of a comet was always recorded by the ancient scribes and we have records of comet observations running back over more than a thousand years prior to the Christian era.

Only a very small proportion of the comets which are discovered ever become visible to the naked eye, and there must be many comets which are never discovered at all. From a study of ancient records there has been, on the average, about one naked eye comet per year. The year 1911, in which there were four such objects, apparently holds the record for maximum number, while there are many years in which no comet at all is visible to the unaided eye.

In a comet which becomes visible to the naked eye there are three general parts: the nucleus, the coma, and the tail. The relative sizes and appearances of these parts change radically as the comet approaches **perihelion.** It is believed that the nucleus (or head) of a comet is a mass of more or less condensed material. It appears much like an ordinary star when the comet is a long way from the sun. As the comet approaches the sun the nucleus increases in brightness and apparently shrinks in size, although this latter characteristic may be an optical illusion since actual measures of the diameter of the head are practically impossible. With the approach to the sun a hazy shell makes its appearance about the nucleus and this so-called coma increases in size. When quite close to the sun the coma seems to stretch out in the direction away from the sun and the tail develops in this direction. The real glory of a comet to the naked eye is this tail. It should be carefully noted that the tail points in a direction directly away from the sun and does not, in general, trail out behind the comet in its motion. The sizes and shapes of the tails of different comets vary in all characteristics. Many comets apparently never develop a tail at all. The tails which do develop have a variety of different shapes and curvature running from short, sharply curved tails, to long straight streamers pointing away from the sun.

Comets are the largest members of the **solar system.** The nucleus may have a diameter up to 10,000 miles, the coma diameters from 10,000–50,000 miles, and the tails have been observed with length as great as several hundred thousand miles. Hence, the volume of a large comet may be greater than the volume of all other members of the solar system combined. In contrast to the enormous bulk of these objects, their masses are so small that they have never been accurately measured

The only available method for determining the mass of a comet is by means of the **perturbations** which they might produce in the **orbits of the planets** or **asteroids.** Many cases of very close approach of comets to objects of known mass have been observed but, while the comet orbit itself may be enormously perturbed, no perturbations have ever been observed in orbits of other objects. The best that can be said regarding cometary masses is that they must be less than one hundred-thousandth the mass of the earth.

Orbits of comets differ from orbits of the other members of the solar system in that they are, in general, much more eccentric than the planetary orbits, and, while the planetary orbit planes are all nearly parallel to the plane of the **ecliptic,** comet orbits are found inclined through practically every angle. The great majority of the orbits which have been determined are found to be parabolic in character which means that the objects will not return to visibility again, two or three objects apparently have hyperbolic orbits, and the remainder are moving about the sun in ellipses, returning to the vicinity of the sun and hence visibility, at periodic intervals. Probably the most noted of all comets is **Halley's comet.** This object was not discovered by Halley, but he was the first one to predict the period of return. Halley's comet has a period of approximately 75 years and has been observed and recorded at practically every return for over a thousand years.

Comparatively little is known regarding the composition and origin of comets. The **spectra** have been carefully studied over a period of years. From these observations we find that comets shine partly by reflected sunlight and partly by radiation from gases, largely hydrocarbon in character, which are excited to incandescence by radiant energy from the sun. There is no valid explanation as to why the sun's radiation should stimulate this activity in comets and not in any of the other members of the solar system. From a careful study of the orbits the preponderance of evidence points to the fact that comets are now and always have been members of the solar system and have evolved and developed with it.

A definite connection has been established between comets and **meteors.** In one well-authenticated case a comet was observed to be disintegrating at several successive returns and finally failed to reappear as a comet. In its place there was a meteoric shower. In several other cases we have meteoric **radiant points** following identical orbits with comets. These observations have led to the hypothesis that the head of a comet may be nothing more or less than a densely packed mass of meteoric material. Why this material should be stirred to activity by the sun's radiation so that it develops a coma or tail is not as yet explained.

There is practically no danger to the earth from comets. There used to be a belief that the tail of a comet contained poisonous gases which might cause wholesale death on the earth if the earth ever came close to the tail. Such belief is entirely without foundation for the gas is in such a highly diffused condition that, even if it were poisonous, a lethal concentration would be highly improbable. During the return of Halley's comet in 1910 the earth passed through the tail and not the slightest effects could be noted either in diminution of sunlight or change in the chemical constitution of the atmosphere. A direct collision with the head of a comet would undoubtedly have a very destructive effect over the portion of the earth where the collision took place. However, from the number of comets and the average orbital characteristics, such a collision is highly improbable. (W.K.G.)

COMMENSALISM. An association between individuals of different species which is beneficial to both but not indispensable. **Ants** and **plant lice** are sometimes associated in this way. The plant lice are guarded by the ants and sometimes carried to a good food supply and the ants receive the sweet honey dew secreted by their charges. (A.W.L.)

COMMISSURE. A transverse nerve cord or fiber tract connecting paired components of the **nervous system.** (A.W.L.)

COMMON SEWER. **Lateral.**

COMMUTATING REACTANCE. This is a reactance connected in the cathode lead of mercury-arc **rectifier** units to insure the current through the tube holding over when the voltage on the conducting **anode** drops until the next anode can pick up conduction. Without this the arc would go out and the tube would need restarting by some auxiliary means. (L.R.Q.)

COMMUTATION. A simple loop of wire rotating in a unidirectional magnetic field has induced in it a reversing or **alternating current.** When the conditions of usage make it desirable to have the current from the **generator** flow in one direction in the external circuit, commutation of some sort is required. The function of a commutator is to effect a reversal of the current induced in the winding of the generator at the proper point to produce a direct current in the connected circuit.

A single loop would generate a current which, when commutated, was pulsating in nature because of the varying rates at which the conductor, during rotation, cuts the lines of force of the **magnetic circuit.** The generator is composed of many such loops properly connected at their ends to the commutator. The commutator for a single loop would be simply a split ring with the two halves insulated not only from each other, but from the frame and shaft of the machine as well. In an actual practical generator having a multiplicity of windings, the commutator consists of a large number of segments of copper assembled around a hub which is attached to the shaft. The segments are thoroughly insulated from each other, usually with mica, and to them the ends of the armature coils are soldered. **Brushes** bearing against the commutator conduct the current away from the generator. (F.T.M., L.R.Q.)

COMMUTATIVE LAW OF ALGEBRA. **Addition** and **Multiplication.**

COMPANDOR. This is the term used to designate the combination of a volume **compressor** and a volume **expander.** (L.R.Q.)

COMPANION CELL. This is a very small elongate **cell** always found in close association with a **sieve tube.** It contains a dense **protoplasm** with a prominent **nucleus** and very small **vacuoles.** It is assumed that in some way they function with the sieve tubes.

For development, see **cambium.** (R.M W.)

COMPARATIVE Anatomy, Physiology, etc. The comparative treatment in any division of biological science focuses attention upon a limited subject, such as **anatomy,** but introduces into its treatment data drawn from many species. This method of study has been applied widely to the vertebrates, hence comparative anatomy is likely to mean comparative anatomy of the vertebrates unless otherwise qualified.

The comparative method is valuable in determining the evolutionary development of organs and the relationship of species. (A.W.L.)

COMPARATOR. An instrument for the accurate measurement of moderately small lengths or distances. The feature common to various forms is a reading

microscope or telescope arranged to travel along a scale, its axis remaining parallel to a fixed line. A typical form consists of a low-power microscope mounted on a carriage movable forward or backward by a **micrometer** screw. The two points or lines whose distance apart is to be measured are brought into the focal plane of the microscope, the cross-hairs of which are adjusted first upon one and then upon the other. For example, the distance to be measured may be that between two star images on an astrographic plate, or the images of two spectrum lines taken by a spectograph; in either case the plate is simply mounted on the stage of the comparator microscope. Another familiar type is the "cathetometer," consisting of a telescope sliding on a vertical scale and provided with a **vernier.** This instrument is used to measure heights of liquid columns, or other differences of level. (L.D.W.)

COMPASS. While this term is sometimes used to indicate an instrument for drawing circles (pair of compasses), we shall confine this article to descriptions of various instruments used for finding **direction** on the surface of the earth.

The oldest and most commonly used is the magnetic compass. The directive forces for this instrument are the horizontal component of **terrestrial magnetism** and, in a properly designed compass, the effect of the vertical component must be reduced as much as possible. The simplest form of the modern instrument is that used by surveyors and consists of a light, thin **magnet** (compass needle), pivoted so that it can turn freely about an axis perpendicular to its length, and with the north-seeking end clearly marked. A **compass card** is mounted in the plane parallel to that in which the compass needle can turn. In using this or any other type of magnetic compass, care must be taken to see that the instrument is level with the axis of rotation vertical. With the instrument properly adjusted, the north-seeking end of the needle will point toward compass north, and true **north** can be determined by the application of the **compass corrections** for **deviation** and **variation.** This simple instrument is perfectly satisfactory for surveyors or for any purpose where it can be mounted on a firm foundation. However, the needle is very sensitive and will swing back and forth for some time before settling down to compass north.

For use on ships and airplanes a more stable system than the compass needle must be employed. On seagoing ships the marine magnetic compass is used. This consists, essentially, of a large number of compass needles bound together in bundles, and these bundles attached by a system of fine, non-magnetic wires to the compass card. Various arrangements of the bundles of needles are employed by different designers in order that the maximum directive force may be obtained. This direction-seeking system is supported above its center of gravity on a jewelled pivot and is mounted in a heavy bowl of non-magnetic material known as the compass bowl. The compass bowl is covered with a heavy glass plate and is completely filled with liquid which reduces friction on the pivot by partially floating the moving system, and also tends to damp out short vibrations. The bowl is heavily weighted on the bottom and contains an expansion chamber to compensate for alterations in the volume of the liquid with changes of temperature. A conspicuous line, known as the lubber's line, is painted on the inside of the bowl. The bowl is mounted on gimbals in the ship's **binnacle** with the lubber's line parallel to the keel of the ship. An **alidade** is frequently used with the marine compass for taking **bearings** of distant objects for purposes of **piloting,** or of celestial objects for the determination of compass corrections. While the liquid tends to damp out short vibrations of the direction-seeking system, nevertheless, the inertia of the system and liquid produces a slow oscillation of the compass card across the magnetic meridian, particularly when the ship is frequently changing headings or is in a heavy sea. This swinging is not too troublesome to the helmsman on an ocean-going vessel for he can watch the compass and obtain a good average reading.

In an airborne ship, where the pilot can only glance at the compass along with a number of other dials, this periodic swing is very troublesome. Furthermore, in airplanes the frequent and severe accelerations make the use of gimbals practically impossible and without them the compass card will frequently rub against the cover of the bowl. The magnetic compass first used by aviators has a floating direction-seeking system similar to that used in the marine type, but the bowl is deeper and the compass card is marked on the outside of a portion of a spherical surface with the graduation visible through a window in the side of the bowl. This instrument is set in the cowl of the plane in front of the observer with the 000° (north) graduation on the south-seeking side of the card so that when the plane is heading north (the pilot looking at the south side of the compass card in front of him), the compass will read 000°. Great care must be taken in using this instrument for taking bearings because of the 180° rotation of the graduations on the card. While this instrument is more convenient for aviators than the standard marine compass, nevertheless, it does swing across the equilibrium position with a slow periodic motion.

The aperiodic (without period) magnetic compass is an improvement on the standard marine instrument. Instead of the numerous bundles of needles, small and very strong magnets are used. These are suspended from the compass card by very fine wires which do not exert appreciable drag on the compass liquid. The whole direction-seeking system is very light and hence has small inertia. The fine wires produce eddy currents in the liquid and these damp out the troublesome swinging back and forth across the equilibrium position. The result is that the card swings quickly into the proper direction and comes to a stop. To avoid the necessity of continually reading the graduations on a moving card, the direction-seeking system carries a single heavy line parallel with the north-seeking direction, with the north end clearly marked. The degree graduations are on a grid ring which can be rotated until any desired graduation coincides with the lubber's line on the bowl. The grid ring carries two conspicuous wires relatively close together, parallel to each other, and in the direction of the 000°–180° graduations on the ring. To follow a desired compass **heading,** the pilot merely rotates the grid until the heading value is at the lubber's line. He then heads the plane so that the "needle" on the direction-seeking unit is parallel to the grid wires. In case a sudden maneuver or air pocket sets the plane off the desired heading, the pilot does not have to look at the graduations but merely brings the plane onto such heading that the "needle" is again parallel to the grid wires. In this, as well as other forms of magnetic compass which cannot be mounted in gimbals in a plane, banking on turns brings the vertical component of the earth's magnetic field into play. (See northerly turning error under **Compass Corrections.**)

The gyro-flux-gate compass is a recent development of a compass which can be used in modern fast and quick maneuvering planes. Two fundamentally important developments are incorporated in this instrument. In the first place, a gyroscopic stabilizer holds the direction-sensitive element horizontal during maneuvers of the plane. In the second place, an **electronic amplifier** increases several hundredfold the strength of the horizontal component of the earth's magnetic field. This increase in field strength is sufficient to permit the use of the gyro-flux-gate compass

within 300 miles of the earth's magnetic poles, whereas the ordinary magnetic compasses are unreliable within 1200 miles of these points. Furthermore, the field strength is sufficient to allow the use of repeaters in various locations about the plane. A repeater is a compass card and lubber's line, whose directive force is obtained by a complicated electrical system from a master compass at a distance. An example of the importance of these repeaters is found in a large bombing plane where the pilot, navigator, and bombardier, all have instruments giving identical readings for the heading of the plane. If separate compasses were used in each location, the chance that they would all agree in reading would be very small, because of unavoidable differences in deviation correction.

The earth-inductor compass was designed a number of years ago for use on aircraft, but has been rendered virtually obsolete by the aperiodic and gyro-flux-gate instruments.

All of the above types of compass depend upon a magnetic field for directive force. This field in practice is the resultant of the earth's magnetic field and the magnetic field of the ship. Compass corrections which are frequently variable must always be used with these instruments.

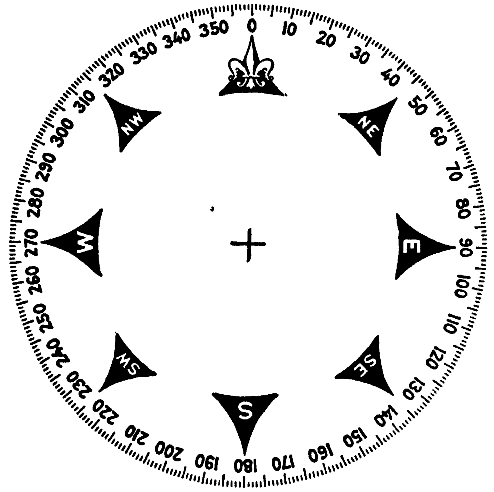
The gyro-compass was developed for the purpose of avoiding the troublesome corrections necessary with the magnetic compass. The first practical installation for seagoing vessels was completed about 1911, and during World War I the gyro-compass was perfected. The detailed theory is too complicated to be undertaken here. The essential feature is a heavy **gyroscope** driven at high speed by electric power. The frame of the gyro rotor is mounted in gimbals and a "ballistic tube" is attached which causes the axis of rotation of the gyro to set itself parallel to the earth's axis of rotation provided the instrument is stationary or moving in the east-west direction. Since the axis of rotation of the earth is in the plane of the **meridian**, the axis of the rotor will point true north on a stationary ship. A compass card may be attached to the gyro, but usually the gyro is used to operate repeaters in various locations about the ship.

On modern ships a master gyro is installed in some well-protected part of the ship and repeaters are located where they will be of greatest value. The electrical circuit which operates the repeaters may be used for a variety of other purposes, such as keeping a constant record of the heading of the ship, and for operating the steering mechanism so that the ship will be held on a predetermined heading. The application of this automatic steering device, frequently referred to as "metal Mike," does not eliminate the necessity of having a helmsman constantly on duty. In cases of emergency such as the appearance of an unexpected obstruction to navigation, the "metal Mike" must be disconnected and the ship steered by hand. A good helmsman can anticipate the action of waves and by constant vigilance and long practice can "touch" the helm in time to prevent a large wave from forcing off the bow. "Metal Mike" has no such powers of observation and the bow would be forced off by a large wave. The gyro would immediately swing the ship back toward proper heading and the next wave would throw the ship off again. The result is a continual strain on the hull of the ship which a good helmsman can avoid. On most ships at present, the steering is done by hand, using a gyro repeater in the binnacle.

On airplanes the rapid accelerations of the ship prevent the use of a true gyro-compass. However, a gyro pilot device may be used to hold a plane on constant heading and altitude, when these factors have been set by standard instruments.

While the gyro-compass is not subject to the compass corrections necessary with the magnetic instrument, nevertheless, it is subject to other corrections when the ship is in motion. These corrections depend on the **course** and speed of the ship, and the **latitude** in which the ship is located. On modern gyro-compasses, devices are incorporated which, when properly set for course, speed, and latitude, will automatically correct the readings of all repeaters to true values. The gyro-compass is a complicated piece of equipment and the multitude of electric contacts and connections frequently cause trouble. Every ship, no matter how complete a gyro-compass installation is aboard, must carry a standard magnetic compass for which the corrections are known at all times, so that it can be used whenever the gyro-compass is out of order. (W.K.G.)

COMPASS CARD. The compass card is a light cardboard or paper disk or annulus which is securely attached to the directing system of a mariner's com-



Compass Card. U. S. Navy Standard.

pass. On this card are painted the "points" and other systems of markings for reading the compass.

During the sailing-ship era, when it was difficult for a helmsman to hold the ship within two or three degrees of a given **heading,** the point and quarter-point system of marking was sufficiently accurate for graduating the compass card. With the increase in ease of steering, the degree system, such as had long been in use on surveyor's compasses, made its appearance on the mariner's compass. Two such degree systems are in common use. One system has zero both at the north and south points of the card and reads in degrees both right and left from the zero's to the east and west points. In such a system the north-west point would be referred to as north 45° west and the north-east point as north 45° east. The present standard U. S. Naval system of marking has north marked zero and reads to the right through the east through 360°. The marking of the card for a naval ship's compass is shown in the accompanying figure. On such a system the north-west point is referred to as 315° and the north-east as 045°. (W.K.G.)

COMPASS CORRECTIONS. The directive force of any magnetic **compass** is the horizontal component of the magnetic field in which the instrument is located. This magnetic field is the resultant of the field of **terrestrial magnetism** and any other fields in the immediate vicinity. The **direction** in which the north-seeking end of the compass points is known as compass north, and to convert directions indicated by the magnetic compass to those referred to true north, the compass corrections must be applied.

The angle between compass and magnetic **north** is known as deviation. It is named east or west depending upon whether the north-seeking end of the compass is east or west of magnetic north. Deviation is the resultant of a large number of local magnetic fields and these are subject to unpredictable changes. A steel ship has a strong magnetic field that is set up in the hull at the yard where the ship is constructed. The direction of this field relative to the keel at the time of launching will depend upon the orientation of the keel during construction. At sea, the direction of this field relative to the keel of the ship may be altered by heavy pounding of the ship by waves, by salvos of gun fire, by severe temperature changes, and a variety of other causes. In addition to the magnetic field of the hull itself, other fields are introduced by such things as cargo, electric currents, degaussing coils, etc. Since deviation is produced by **magnetic** fields connected with the ship, its value will change with different headings. The ship's **binnacle** contains a number of movable magnets which may be adjusted to reduce deviation to a minimum value. In port, a professional compass adjuster will swing the ship (put the ship on various headings completely around the compass) and determine the deviation on each heading. He then adjusts the magnets in the binnacle. After the compass adjusting is complete the adjuster will issue a calibration card or table showing the value of the deviation for each 15° of heading of the ship. At sea, the navigator must check this correction on different headings whenever possible by taking compass **bearings** of distant objects of known **azimuth,** or of celestial objects and computing their azimuths. In case the observed values do not agree with those given on the calibration card, the navigating officer must swing the ship and redetermine the entire curve just as soon as possible.

Correcting the compass heading for deviation will give the magnetic heading of the ship. This must be further corrected for variation to obtain the true heading. The angle between magnetic north and true north is known as variation. Variation is named east or west depending on whether magnetic north is east or west of true north. (N.B. Unfortunately a confusion of terminology is in common use for describing this compass correction. Most surveyors, some geologists, and a few other scientists use the term **declination** instead of variation for this angle. The standard practice in the American air services, and in the U. S. Navy and Merchant Marine, is to use the term variation.) Variation differs from place to place on the surface of the earth and from day to day in any particular locality. As a result of long and painstaking research on terrestrial magnetism, it is possible to plot on **charts** the value of the variation for any locality at some particular date and the rate of change of variation. Curves, known as isogonic lines, may be drawn through places of equal variation. Whenever old surveys are being used, it is important to determine whether the directions given are magnetic or true. If directions are given as magnetic, it is necessary to obtain the variation for the year of the survey to obtain the true directions.

The standard U. S. Navy practice in correcting directions from compass to true is to first apply deviation and then variation. East deviations and variations are marked plus, and west values are marked minus. With this convention in signs we have compass + deviation = magnetic. Magnetic + variation = true. The summations are to be made with due regard of the algebraic signs. A convenient phrase for remembering this method is *C*an *D*ead *M*en *V*ote *T*wice. There are many other conventional methods employed by different services such as Army Air Corps, Civil Aeronautics Administration, etc., for compass correction. No one of these can be called "the best method." The important thing is to know what you are doing and do it properly.

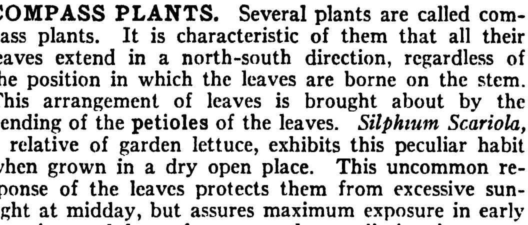
The above corrections are based on the assumption that the only force effective on the direction-seeking unit of the compass is the resultant of the earth's field and the fields of the ship. In all airplane compasses, other than the new gyro-flux-gate type, banking the plane brings the vertical component into play. If the plane is turning there will also be a centrifugal effect due to the turn. These two factors are in opposite directions and are of greatest magnitude in the northern hemisphere when a plane is turning from a north heading. Under certain conditions the compass may indicate a right turn when the plane turns left, and sometimes may indicate first a left and then a right turn. There are no set rules of correction for this so-called northerly turning error, but lives have been lost because of the failure of pilots to realize and allow for it. Certain gyroscopic devices have been developed to indicate the actual turning of a plane, but the magnetic compass should never be used for this purpose. (W.K.G.)

COMPASS PLANTS. Several plants are called compass plants. It is characteristic of them that all their leaves extend in a north-south direction, regardless of the position in which the leaves are borne on the stem. This arrangement of leaves is brought about by the bending of the **petioles** of the leaves. *Silphium Scariola,* a relative of garden lettuce, exhibits this peculiar habit when grown in a dry open place. This uncommon response of the leaves protects them from excessive sunlight at midday, but assures maximum exposure in early morning and late afternoon, when radiation is not so intense. (R.M.W.)

COMPENSATION SAC. A reservoir opening to the exterior in certain **Bryozoa** which fills with water when the tentacles are extruded and empties when they are retracted. (A.W.L.)

COMPENSATOR. While this term may serve to designate any device used for compensation, there are two specific applications of its use.

In physics the term compensator is ordinarily restricted to an arrangement for measuring the phase difference between the two components of elliptically **polarized light.** This is accomplished by introducing a known, opposite phase difference of equal magnitude, which reduces the existing phase difference to zero. The



A. Diagrammatic sketch of Babinet Compensator: angle of wedges much exaggerated. Hatching and stippling indicate direction of crystal axes. B. Shows wedges displaced.

most familiar form, devised by Babinet, consists of two quartz wedges, with thin optic axes at right angles to each other. When passed through this apparatus and a **Nicol prism** set to extinguish light plane-polarized at 45° to either axis, any given elliptically polarized light produces a system of parallel dark bands. Plane-polarized light is first used (zero phase difference), then the elliptic light of unknown phase difference, and the relative displacement of the wedges necessary to restore the bands to their original position gives the phase difference required.

Another use of the term compensator is in electrical engineering. When a motor is to be started other than

by direct connection to the supply line, some means must be incorporated in the circuit to limit the current taken during the starting period. A method frequently used to start a-c motors which are too large to be directly connected for starting, is to decrease the impressed voltage during the starting period. The term compensator usually refers to the automatic transformers, switches, and wiring employed to limit the starting current for the squirrel-cage type of a-c motor. This equipment is enclosed in a case through which projects an operating handle which has three positions, "off," "starting," and "running." This handle controls a double-throw switch. When in starting position, the switch is thrown so as to connect the motor to the line through an auto-transformer, which reduces the voltage to an amount suitable for starting purposes. When in the running position, the switch connects the motor directly to the line through fuses, and full line voltage is impressed upon the motor windings. (See **Starter, Motor.**) (L.D.W., F.T.M.)

COMPETENT. As defined in terms of **structural geology** see **Incompetent.** (R.M.F.)

COMPLEMENTAL MALE. 1. In certain **barnacles** which are normally **hermaphrodite** a few individuals lack female organs and are called complemental males. 2. In colonies of white ants, termite reproduction is carried on principally by a highly specialized king and queen. Other sexually mature individuals resembling the immature insects are known as the second reproductive caste. The males of this caste are complemental males. (A.W.L.)

COMPLEMENTARY COLORS. Color.

COMPLEMENTARY FUNCTION OF A LINEAR DIFFERENTIAL EQUATION. Linear Differential Equations.

COMPLEX FRACTIONS. A complex fraction is one whose numerator or denominator or both are fractions or mixed expressions. A complex fraction may be reduced to simpler form by multiplying every term of the numerator and denominator by the **least common multiple** of the denominators of the subsidiary fractions. (L.L.S.)

COMPLEX NUMBERS. An imaginary number is a square root of a negative real number. Every imaginary number can be expressed as a product of a real number by the so-called imaginary unit $\sqrt{-1}$; thus, $\sqrt{-4} = 2\sqrt{-1}$.

Sometimes the term imaginary number is used for what we call complex numbers; to emphasize the distinction, the term pure imaginary is sometimes used for the square roots of negative real numbers.

The imaginary number $\sqrt{-1}$ is often called the imaginary unit, and it is generally denoted by the letter i for brevity; its fundamental property is expressed by $i^2 = -1$. In electrical engineering work, the letter j is often used in place of i for the imaginary unit.

The successive powers of the imaginary unit are: i, $i^2 = -1$, $i^3 = -i$, $i^4 = +1$, $i^5 = +i$, $i^6 = -1$, $i^7 = -i$, $i^8 = +1$, and so forth in cycles of four.

Complex numbers are numbers of the form $a + bi$, where a and b are real numbers and i is the imaginary unit; they consist therefore of a real part a and a pure imaginary part bi.

The complex numbers $a + bi$ and $a - bi$ are said to be conjugate to each other.

Two complex numbers are defined as equal when their real parts are equal and their imaginary parts are equal. When any two expressions involving real and imaginary parts are equal, we may equate their real and imaginary parts separately.

The four fundamental operations with complex numbers are expressed by the formulae:

$$(a + bi) \pm (c + di) = (a \pm c) + (b \pm d)i,$$

$$(a + bi)(c + di) = (ac - bd) + (ad + bc)i,$$

$$\frac{a + bi}{c + di} = \frac{ac + bd}{c^2 + d^2} + \frac{bc - ad}{c^2 + d^2}\, i.$$

That is, to add (or subtract) complex numbers, add (or subtract) the real and imaginary parts separately; to multiply two complex numbers, multiply them as though they were ordinary binomials and substitute $i^2 = -1$; to divide two complex numbers, multiply numerator and denominator by the conjugate of the denominator.

Since a complex number $x + yi$ depends on two real numbers x and y, complex numbers require a 2-dimensional field, such as the plane, for their graphic representation.

Argand's diagram represents a complex number as $x + yi$ graphically by the point whose **rectangular coordinates** are x and y, or by the corresponding **vector** from the origin to this point, as shown in Fig. 1.

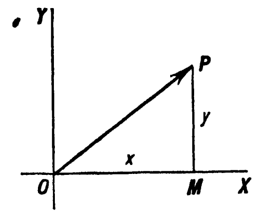


Fig. 1.

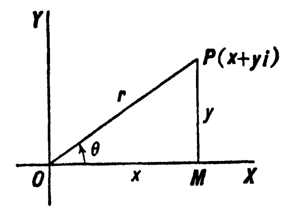

Fig. 2.

Let the complex number $x + yi$ be represented graphically by the point $P(x, y)$ in rectangular coordinates, by Argand's diagram, and let the **polar coordinates** of P be (r, θ). (See Fig. 2) Then $r = OP = \sqrt{x^2 + y^2}$, and $\theta = \angle XOP = \arctan (y/x)$. Then the radius vector r is called the absolute value (or modulus) of the complex number and is denoted by the symbol $|x + yi|$, and the vectorial angle θ is called the amplitude (or argument) of the complex number and is occasionally denoted by $am(x + yi)$. The complex number $x + yi$ may then be represented in terms of r and θ by the expression

$$r(\cos\theta + i \sin\theta),$$

(sometimes abbreviated into $r \operatorname{cis} \theta$), which is called the polar (or trigonometric) form of the complex number.

The product and quotient of two complex numbers in polar form are expressed by the formulae:

$$r_1(\cos\theta_1 + i \sin\theta_1) \cdot r_2(\cos\theta_2 + i \sin\theta_2) = r_1 r_2[\cos(\theta_1 + \theta_2) + i \sin(\theta_1 + \theta_2)],$$

$$\frac{r_1(\cos\theta_1 + i \sin\theta_1)}{r_2(\cos\theta_2 + i \sin\theta_2)} = \frac{r_1}{r_2}[\cos(\theta_1 - \theta_2) + i \sin(\theta_1 - \theta_2)].$$

(L.L.S.)

COMPOSITE BEAM. A **beam** which is composed of two materials properly bonded together and having different modulii of elasticity (see **Modulus of Elasticity**) is called a composite beam. The **reinforced concrete** beam and wood beams reinforced with steel plates are typical examples.

The analysis of composite beams depends on the assumption that a plane section before bending remains plane after the **load** is applied. Therefore the two materials must be connected in such a way that they will act as a unit. This condition is realized in the reinforced concrete beam by means of the bond (see **Bond Stress**) between the reinforcing rods and the concrete. In the case of reinforced wood beams the parts are connected by bolts properly spaced to resist the shearing forces (see **Shear**) between the plates and the beam.

The flexure formula is applicable to composite beams if the beam is transformed into an equivalent homogeneous section by means of the transformed area method which is found in texts on strength of materials and reinforced concrete design. (C.W.C.)

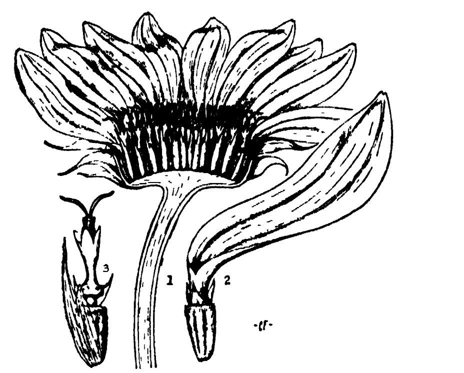
COMPOSITE COURSE. The shortest **track** between two points on the surface of the earth is a great circle if we neglect the slight oblateness. However, the following of such a track has two fundamental disadvantages: 1. Such a course is a **rhumb line** only in the particular cases of two points both on the **equator,** or two points on the same **meridian** of longitude. 2. Such a course will frequently lead the vessel into impossible positions (e.g., if the two points are in the same **latitude** but differ by 180° in longitude the great-circle track between them would lead over the nearest pole).

A composite course is a combination of great-circle and rhumb-line courses designed to carry a ship from one point to another by the shortest practicable path. In case the great-circle track does not lead the ship into impossible positions the composite course is usually a series of rhumb-line courses to successive positions along the great-circle track, the rhumb-line distances so figured that the course of the ship will be altered at convenient times (e.g., the changing of the watch). In case the great-circle course leads the ship into danger the problem of computing the composite course is one of a number of compromises which are different for every problem. A good example of such a composite course may be obtained by examining the steamer lanes across the Atlantic Ocean which will be found on many terrestrial globes. (W.K.G.)

COMPOSITE FAMILY. Compositae. This is the largest family within the plant kingdom and contains over twelve thousand species in over eight hundred genera. Furthermore, it represents the highest evolutionary attainment among dicotyledonous plants. Composites are mostly herbaceous plants, distributed practically all over the earth. The few members which are shrubs or trees are largely limited to tropical regions, especially to island floras. The family is divided into two groups, distinguished by the nature of its flowers. The plants of one group have latex vessels usually containing a white **latex,** those of the other group lack latex, but in most cases contain oil-canals with acrid or bitter watery contents.

The leaves of most composites are alternate, often entirely radical, although in a few cases they are opposite, as in the sunflower, *Helianthus annuus,* or whorled, as in species of *Eupatorium.* Stipules are seldom found in this family. The root is most commonly a tap-root, frequently much thickened, as in the dandelion. The inflorescence is of the type known as a head, or capitulum. Often the heads are aggregated in larger inflorescences of various types, as **panicles** or **cymes** or spikes. Commonly the single head is inaccurately regarded as a flower, rather than as an inflorescence. Surrounding the head is a group of bracts, making up the involucre. These **bracts** are usually green and serve to protect the flowers before they are mature and also to protect the maturing fruit. The flowers of a head are arranged on the enlarged end of the stem or axis, called the receptacle. This receptacle may be flat and disk-shaped, as in the common sunflower, conical as in the yellow daisy, *Rudbeckia hirta,* or otherwise. It may be smooth or covered with hairs or scales.

The individual flowers show considerable difference in structure. In many species the flowers of a head are



Flowers and flower-heads of a sunflower, *Helianthus.* 1, the flowerhead, cut so as to show the relation of the ray and disk flowers to the end of the stem 2, a single ray-flower. 3, a single disk flower.

all alike and all perfect. In other species they are of two kinds, one called ligulate and the other tubular. Ligulate flowers, also called ray-flowers, are irregular, but bilaterally symmetrical; tubular flowers, also called disk flowers, are regular. Both types occur in the head of the sunflower, where the tubular or disk flowers occupy the larger part of the receptacle, the ray-flowers being the conspicuous yellow flowers forming a ring around the periphery of the receptacle, just inside the involucral bracts. Each disk flower is perfect and regular. The **calyx** appears in different genera as bristles, barbs, scales, or teeth, and sometimes is completely lacking. It is known as the pappus and occurs at the apex of the inferior **ovary.** Often the pappus becomes a very important structure in the dissemination of the fruit. The **corolla** is tubular and 5-lobed, and inserted on the apex of the ovary. The short filaments of the five **stamens** are inserted on the base of the corolla tube, while the **anthers** are attached to each other by their edges, forming a tube which surrounds the style. The pollen is discharged into the anther tube. The single **pistil** has an inferior ovary containing a single erect **ovule,** a simple style which splits into two parts, the inner surfaces of which are stigmatic. The fruit is usually of the type called an **achene.** Nectar is secreted in a ring-shaped **nectary** which surrounds the base of the style, located at the base of the tubular corolla. This nectar attracts insects, but only those with mouth parts sufficiently long to reach to the bottom of the corolla tube can obtain it. When the flower opens the **pollen** is shed into the anther tube. At the base of this tube the style, as yet unforked, occurs. This style elongates, pushing like a ramrod against the pollen above it, and causing an accumulation of pollen at the upper end of the anther tube. Insects seeking the nectar necessarily come in contact with the pollen masses,

Flower-head and flowers of the dandelion, *Taraxacum.* 1, the inflorescence or head, composed of many flowers upon a flattened stem. 2, a single flower more enlarged. 3, a single fruit.

which are thus likely to be transferred to another flower as the insect goes about collecting nectar. However, should insect-pollination fail, self-pollination is assured in many species, by the behavior of the styles, which emerge from the anther tube, protrude considerably, and then split and coil backwards so that the inner stigmatic surface rolls down into contact with the pollen. In some cases this self-pollination is almost the only method. Many species are self-sterile, thus requiring cross-pollination by insects.

The ligulate or ray flowers differ from the disk flowers in having the corolla of five united petals forming a tubular base which gradually emerges into a flat strap-shaped lateral structure with five teeth at its tip. Growing from the tube of the corolla are the small **stigma** and the five coalesced stamens. In many species where the rays flowers are marginal in the head they are entirely sterile or are pistillate.

The Composites are divided into two groups. If all the flowers of a head are ligulate the plant is a member of the Liguliflorae. This group contains, among other common plants, chicory, dandelion, and lettuce. It is in this group, also, that **latex** occurs. The other group, the Tubuliflorae, comprises all Composites characterized by disk flowers. These may occupy only the central portion of the head, or the latter may be entirely of disk flowers. Examples of this group are sunflowers, daisies, asters and goldenrods.

After **pollination** takes place the involucral bracts close over the head, pressing tightly against it and so protecting the developing **fruit**. The **pappus** becomes a conspicuous part of the fruit in many cases and is a very important factor in insuring scattering of the fruit. In some cases the pappus forms a parasol-like group of fine radiating hairs at the tip of a long beak of the achene. These hairs make the achene buoyant, and hence capable of being carried long distances by air currents. Often the base of the hair is **hygroscopic**, responding to changes in moisture, so that the parasol-like structure opens and closes with decrease or increase of humidity, which may help to loosen the achene from the receptacle, and also to shove it along over the surface of the ground, or to push it into a crack in the soil. In *Bidens*, often called beggar-ticks or beggar-lice, the pappus is in the form of stiff usually downwardly barbed bristles which catch into the hair of passing animals or the clothing of man and so are carried about, finally breaking off and falling to the ground. In the burdock, *Arctium*, the involucral bracts form recurved hooks which serve in the same way, the entire head often breaking off and being transported. In thistles the pappus takes the form of a tuft of long silky hairs which enable the achene to float readily through the air. In many cases members of the composite family have no special pappus development, seed dispersal being entirely accidental.

The reasons which suggest that the Composite Family is highest in rank are found in the massing of the individual flowers into a compact head surrounded by protecting bracts, the structure of the individual flower with its inferior ovary, its united petals forming a corolla tube, the united anthers forming the anther tube, and the reduction of the number of carpels to two with but one ovule developing.

For so large a family comparatively few of its species are used by man. Several are extensively cultivated for ornament, the flowers often becoming very large and double and extremely showy, as in the case of the *Chrysanthemum* and *Dahlia*. Less showy ornamentals are the *Aster, Bellis, Tagetes* and *Calendula,* among others. Some composites yield oils or other substances useful to man, as *Arnica, Artemisia, Tanacetum, Calendula, Chrysanthemum* and *Helianthus*. A few are used as food, such as Lettuce, Artichokes, Endive, Chicory, Salsify and Dandelion.

Lettuce, *Lactuca sativa,* is an annual herb which is native to Europe, Asia and northern Africa. The plant is very leafy and contains a milk-white **latex**. In young plants the leaves are crowded on a short stem, forming a close rosette; in older plants the stem elongates greatly and bears a panicle of heads of yellowish flowers. The achenes are flat, ribbed, and contracted into a slender beak bearing numerous soft white or brownish pappus hairs which radiate outward like a parasol. Many varieties have been developed in cultivation. Lettuce is used almost entirely as a salad plant.

Endive, *Cichorium endivia,* is an annual or biennial herb having many basal leaves which in cultivated forms have become very much dissected and crisped. Mature plants are tall-stemmed and have purple, rarely white, flowers, all ligulate. The plant is used either as a salad plant or as a pot-herb. It is a native of India, and has long been cultivated in European countries. It is becoming more popular in the United States.

Chicory, *Cichorium intybus,* also called succory, is one of the many European plants which has become a persistent weed on introduction to North America. It is a perennial plant having a deep tap-root and a stiff tough stem two or three feet tall. Root leaves are numerous, forming a dense basal rosette: stem leaves are small, of various shapes, and clasping the stem. The flowers are usually blue, sometimes pink, or white. The plant is used as a salad plant or as a pot-herb, often being mistaken for dandelion. Its roots have been dried, ground and roasted and used as a substitute for coffee. There are several varieties in cultivation, one of which, Witloof chicory, finds considerable favor as a salad plant.

Salsify, *Tragopogon porrifolius,* or Oyster plant, is a plant indigenous to southern Europe. It is a hardy biennial having a thick tap-root 8-12″ long and an inch or two in diameter. This root is formed during the first year of growth when it bears a crowd of leaves. During the second year's growth the rather succulent branching stems grow up two or three feet tall. The stem leaves are alternate, entire and clasping, and have a smooth waxy surface. The flower heads are borne on long hollow stalks, or peduncles, and have purple flowers, all ligulate. The achenes are linear and have a long slender beak with radiating pappus hairs at its tip. The roots of the plant have a flavor suggestive of that of oysters, and are used as a cooked vegetable. A yellow-flowered species also occurs, and has been widely introduced into the United States.

Scolymus hispanicus, another southern European member of the Composite Family, is also known as an Oyster plant, or salsify, usually being designated as Spanish salsify. *Scorzonera hispanica,* Composite Family, is black salsify.

Artichoke, or Jerusalem Artichoke, *Helianthus tuberosus,* is sometimes called by its Italian name, girosole, meaning sunflower, which corrupted into English becomes Jerusalem Artichoke. It is a perennial herbaceous plant having thick fleshy rootstocks which bear somewhat irregular tubers with very evident "eyes" (actually dormant **buds**). The erect stems are 6′ or more tall, stout and branching. The leaves are simple, ovate, and long-petioled. The heads are either solitary or in **corymbs,** and are composed of central disk flowers and marginal ray flowers, both yellow. The achenes are thick and hairy, with two deciduous pappus scales. The tubers are used largely as stock food, especially for hogs, but are also eaten by humans.

Helianthus annuus, the common sunflower, is frequently grown, partly for ornament, partly for curiosity because of the tremendous flower heads which often contain an enormous number of flowers, and partly for the seeds. These seeds are fed to poultry and larger caged birds. From the seeds, sunflower seed oil is expressed.

Globe artichoke, *Cynara scolymus,* is another Composite which is grown for food. It is a herbaceous perennial native in northern Africa. The flowers form large globular heads surrounded by several rows of fleshy

bracts. The basal portions of each bract and the thick fleshy receptacle are cooked and eaten. The blanched leaves of a related species, *Cynara Cardunculus,* or cardoon, are often eaten like celery.

Dandelion, *Taraxacum officinale,* is a stemless perennial herb, having a thick tap-root and a rosette of basal leaves which grow close to the ground. Contraction of the root each year keeps the leaves of that year's growth at the ground level. The heads, composed of yellow ligulate flowers, are borne singly on hollow peduncles. When the **achenes** are mature the **peduncle** elongates greatly, lifting the achenes well above the ground. Each achene is beaked and has a crown of pappus hairs which aid it in floating through the air. The dandelion is frequently used as a pot-herb, and is grown extensively. Wild plants, often pestiferous weeds in lawns, are much gathered in the spring for greens. The root contains a glucoside taraxirin, and is used medicinally as a tonic. Another species of dandelion, *Taraxacum kok-saghyz,* is extensively cultivated, especially in Russia, as a source of rubber.

Several other members of the Composite Family have medicinal value. The young roots of the common burdock, *Arctium lappa,* are used in southern Europe and Asia as a drug plant. The stem tips and young leaves of *Eupatorium perfoliatum,* a native North American plant, are used as a stimulant and tonic, and in the making of compounds to relieve colds and fevers. Species of *Grindelia,* native in western United States, are used in preparations to relieve asthma. *Matricaria chamomilla,* a native of Europe, is a mild stimulant and tonic plant, as is also *Anthemis nobilis.*

Certain species of **Artemisia** are used in several ways. *Arnica montana,* of western United States, is another stimulant and tonic plant. *Calendula officinalis,* a strong-smelling garden annual frequently grown for its brilliant yellow or orange flowers, contains a volatile oil, and serves a variety of uses in the East and in Europe. Species of Chrysanthemum are grown extensively for their ornamental flower heads. *Chrysanthemum parthenium* is a febrifuge, popularly used to cure mild fevers. The entire flower heads of *Chrysanthemum roseum, Chrysanthemum cinerariaefolium* and *C.* (*Anacyclus*) *pyrethrum* are ground up and used as insect powders, under the name of pyrethrum.

Several members of this family contain poisonous substances which cause serious consequences when eaten by stock. *Helenium autumnale,* the sneeze-weed, is a perennial herb with smooth stem 2–6′ tall, pointed lanceolate leaves, and bright yellow flowers in heads containing both ray and disk flowers. It occurs widely scattered in North America. Eaten in quantities it causes fatal results in cattle, horses and sheep. White Snakeroot, *Eupatorium urticaefolium,* another perennial with stem 1–5′ tall, with opposite ovate leaves and dense masses of small heads of white flowers, occurs widespread in northern North America. It also produces fatal results if eaten by stock.

Ragweed, *Ambrosia artemisiifolia* and related species, is another widely known member of the family. It is a native plant, widely distributed and usually very abundant. It is a branching annual, ordinarily growing 2–4′ tall. The leaves are finely divided and rather thin. The flower heads are of two sorts, the staminate heads are borne in elongated racemes, while the pistillate are borne in clusters. Flowers are produced in late summer and autumn and, unlike most composites, are wind-pollinated. The pollen of these plants is one of the principal causes of hay fever. (See **Allergy.**) (R.M.W.)

COMPOSITE SET. Telegraphy.

COMPOSITION, CHEMICAL. Chemical Composition.

COMPOSITION OF VECTORS. Vector Addition.

COMPOUND, CHEMICAL. Chemical Composition.

COMPOUND CURVE. Circular Curve.

COMPOUND ENGINE. A **steam engine** in which the total pressure drop of the steam between throttle and exhaust conditions is divided into two or more stages is said to be compounded when the expansion in each stage is performed in a separate **cylinder.** By common usage the engine in which steam is successively expanded in two cylinders is called a compound engine. If three cylinders are used, the engine is triple expansion; if four cylinders, quadruple expansion, etc. There are three very definite advantages attending compounding an engine. Any one cylinder does not have the big difference in temperature between incoming and outgoing steam that exists in a simple steam engine. The amount of initial condensation of the steam consumed in warming the cylinder and ports at the beginning of each stroke is thereby lessened. The confining of the highest pressure steam to the small high-pressure cylinder makes it possible to design the low-pressure cylinder, which is always the largest, against much lower loading forces than in the case of the simple engine, where one cylinder must not only meet the requirements of the highest pressure, but also contain the greatest volume of the steam. Furthermore, the flow to the low-pressure cylinder may be split between two identical low-pressure cylinders, thus reducing the cylinder size.

A compound engine may be tandem-compounded or cross-compounded. Tandem compounding refers to the arrangement wherein the different cylinders are in line and their pistons are fastened to the same piston rod. One crank and one connecting rod are required in a tandem compound engine. The cross-compounded engine has cylinders set with axes parallel, each cylinder having its own piston rod and connecting rod, the latter bearing on separate cranks of the crankshaft. There is more mechanical friction in the cross-compounded engine, but the cranks may be set at an angle to each other, and the rotative effort made more uniform. Steam exhausted from the high or intermediate pressure cylinder in a tandem engine may be passed directly to the next lower pressure cylinder through short interconnecting piping since the pistons move in synchromism. A steam receiver is necessary between the cylinders of a cross-compounded engine because of the angle between the cranks. The compound engine was at one time built in very large sizes, and a quadruple expansion engine was no uncommon thing, but while the engine was efficient, it was bulky, slow-speed, and extremely costly, and has been rendered obsolete by the steam turbine. There are, however, many multiple expansion engines in service at present in excellent working condition, and they will probably continue to give good service for many years, but new installations at present are made with either the simple steam engine or the steam turbine. (F.T.M.)

COMPOUND FRACTURE. Fracture.

COMPOUND GEAR. Gear Train.

COMPOUND GENERATOR. Generator.

COMPOUND PROBABILITY. Probability.

COMPOUND TURBINE. A compound **turbine** is one in which there are two casings—high- and low-pressure. The steam is partially expanded in the high-pressure casing, then exhausted to the low-pressure casing. The rotor arrangements may be either tandem- or cross-compound. Two generators must be supplied to cross-compounded turbines. The principal advantages of compounding a turbine are the reduction in physical size of any one casing, the confinement of the highest pres-

sures to the smaller casing, which may be built of steel, and the possibility of divided flow in the low-pressure casing for the purpose of equalizing end thrusts. (F.T.M.)

COMPRESSIBILITY, AERODYNAMIC. The "incompressible fluid" theory of classical hydrodynamics has proved most useful for the estimation of aerodynamic parameters, and when applied to problems of low-speed flight has yielded sufficiently accurate results. It has been found, however, that the flow pattern about a body moving through the air at high speeds is affected to a large degree by changes in density resulting from compression or expansion of the fluid. Consequently, aerodynamic coefficients based on an incompressible-flow theory are in considerable error when applied to airplanes moving at high speeds. An understanding of compressible flows is, therefore, of the utmost importance to the designer of high-speed aircraft.

In the study of compressibility phenomena as applied to aerodynamic problems, airplane speeds are classified according to their relation to the speed of sound in air. The speed of sound is taken as a reference velocity because it is a function of fluid elasticity. As applied to compressible flows this means that the amount of pressure necessary to effect a given change in density in any fluid is proportional to the speed of sound in the fluid. Since the pressure is proportional to the square of the velocity, the velocity which a body may attain before appreciable density changes occur is also proportional to the velocity of sound in the fluid. It is apparent, therefore, that the flow pattern about a body will be altered by density changes to a degree dependent upon the ratio of the velocity of the body to the velocity of sound. This ratio is known as the *Mach number* and is taken as an index of the effects of compressibility on the flow pattern. A curve showing the variation of the speed of sound with altitude is presented in Fig. 1.

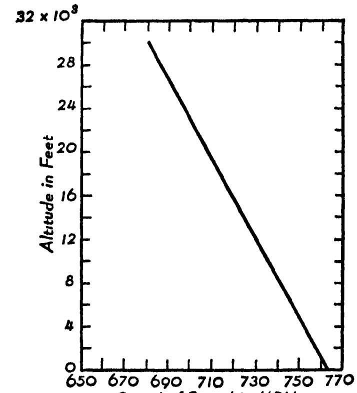


Fig. 1. Speed of sound as a function of altitude (sea-level temperature 60° F.).

In order to show quantitatively the changes in air density associated with increasing Mach number the following table has been prepared. This table is based on an adiabatic flow through a converging nozzle. M is the stream Mach number and ρ/ρ_s is the ratio of the corresponding air density to the density at static conditions.

M	ρ/ρ_s
.2	.981
.4	.925
.6	.841
.8	.742
1.0	.635

The preceding discussion fully accounts for the effects of compressibility only at Mach numbers less than one, or at subsonic speeds. As air speeds approach and attain the velocity of sound, radical changes occur in the flow pattern which do not result entirely from changes in air density. The flow pattern in a perfect incompressible fluid is instantaneously influenced at all points by pressure changes occurring at any point in the flow field. A consideration of the theory of elasticity as applied to fluids, however, indicates that the effects of small pressure changes in a real fluid are transmitted throughout the fluid in the form of waves which travel at the speed of sound. It may be seen, then, that the effects of a pressure change which occurs behind the critical point at which the speed of sound has been reached cannot influence the flow field ahead of the point.

Since at the critical point the forward motion of the pressure waves is completely arrested by an air stream velocity equal to the velocity of wave propagation, a wave front is formed at the critical point. This wave front constitutes a sharp discontinuity in the flow with which is associated large increases in pressure, density and temperature and a decrease in velocity. Such a wave front with its attendant discontinuities is known as a shock wave. The flow field about a body traveling at or near sonic velocities will be radically different from that at low speeds.

Once the velocity has increased beyond the sonic range and attained a sufficiently high supersonic value, the shock wave will be forced downstream and the flow at the original point of shock will be comparatively smooth. However, the flow pattern at supersonic speeds will bear little resemblance to that which obtains at low speeds.

High-speed flight is greatly complicated by the compressibility phenomena which have been described. An attempt will be made to outline the more important considerations in the aerodynamics of high-speed flight.

The change in aerodynamic characteristics which results from fluid compressibility is greatest when shock waves form on some part of the airplane such as an airfoil or cowling. The forward velocity of the airplane which corresponds to the formation of shock waves is called the critical speed. The critical airplane speed is always less than the velocity of sound since the local velocity over the airfoil surfaces and other components is in excess of the forward speed of the airplane. The critical Mach number is the ratio of the critical airplane speed to the speed of sound.

The airfoil section usually predominates as the factor which controls the effects of compressibility on the characteristics of high-speed airplanes. The variation in

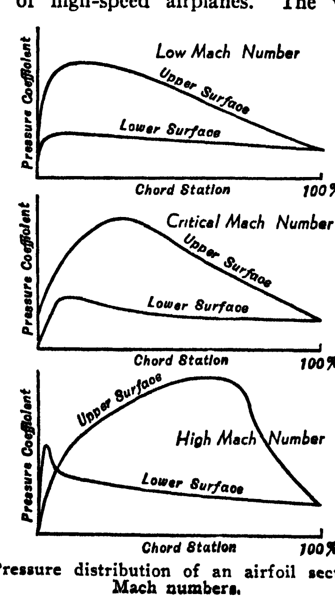

Fig. 2. Pressure distribution of an airfoil section at three Mach numbers.

pressure distribution around an airfoil as the Mach number is increased is shown in Fig. 2. Both flight and wind-tunnel tests have shown that this change in pressure distribution affects the following important airfoil parameters:

1. The drag coefficient, C_D.
2. The slope of the lift curve $\frac{dC_l}{d\alpha}$.
3. The pitching-moment coefficient, C_M.
4. The maximum lift coefficient, $C_{l\ \max}$.

The drag coefficient suffers most, its value increasing tremendously as the critical Mach number is reached. The large increase in drag results not only from energy loss in the shock wave but also from the large positive pressure gradient existing across the shock. Such a pressure gradient causes boundary-layer separation which results in a wide, turbulent wake with its attendant form-drag. A curve is presented in Fig. 3 which shows

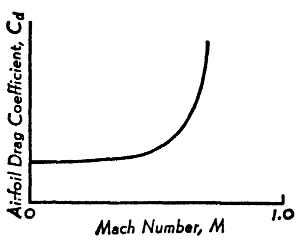

Fig. 3. Variation of airfoil drag coefficient with Mach number.

qualitatively the variation of profile-drag coefficient with Mach number. In terms of airplane performance, the increase in drag which occurs at the critical speed indicates that a tremendous amount of power would be required for an airplane to fly through the sonic range of speeds and reach speeds above the speed of sound.

A loss in maximum lift coefficient occurs as the critical speed is approached. However, airplanes do not operate

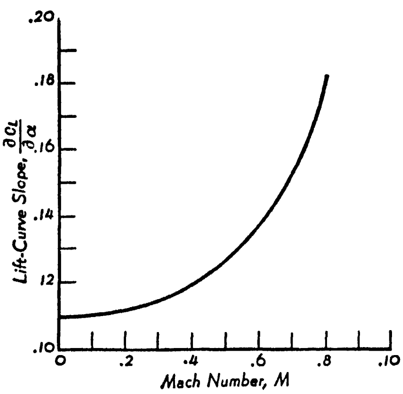

Fig. 4. Change of lift-curve slope with increasing Mach number.

at high lift coefficients when traveling at high speeds. The changes in lift-curve slope and pitching-moment coefficient which occur with increasing Mach numbers are shown in Figs. 4 and 5. The variation of lift-curve

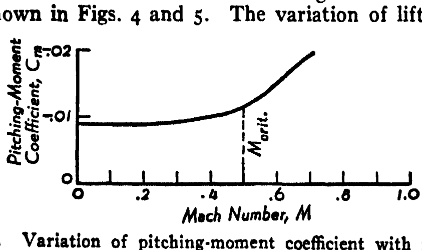

Fig. 5. Variation of pitching-moment coefficient with increasing Mach number.

slope with Mach number was calculated from Glauert's approximately correct theoretical relation which states that the change in lift-curve slope is proportional to $\frac{1}{\sqrt{1 - M^2}}$, where M is the free-stream Mach number.

The changes in pitching-moment coefficient and lift-curve slope indicate a considerable variation in the external forces acting on the lifting surfaces of airplanes traveling at high speeds. Unless the changes in C_M and $\frac{dC_l}{d\alpha}$ are taken into consideration in the design of high-speed airplanes, complete loss of control and stability may result at high speeds. The large turbulent wake discussed in connection with the drag of bodies at shock speeds also has an adverse effect on the control and stability. The angle of downwash and thus the trim of the airplane will change instantly when the wake widens and the plane may be thrown completely out of control. The large turbulent wake may also cause serious control-surface buffeting.

Knowledge of compressible flows is still very limited. The most fruitful methods of obtaining information about compressibility phenomena have been found in the field of wind-tunnel testing. Reliable data are very hard to obtain at speeds in the sonic range, however, and it is in this range that quantitative results are most needed. Tremendous mathematical difficulties are associated with problems involving compressible flows. It is to be hoped, however, that the mathematician working with those engaged in experimental research will eventually develop a reasonably complete body of knowledge regarding compressible flows. (F.T.M.)

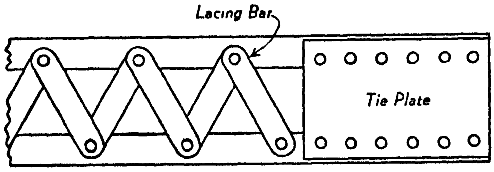
COMPRESSION. Compression is descriptive of the decrease of volume of a compressible substance due to the application of pressure. The common example of compression is found in cylinders filled with gas being compressed by the motion of a piston moving in the cylinder. The pressure increase required for any given reduction of volume of a gas depends upon the particular condition surrounding the act of compression; for example, if the cylinder is thoroughly insulated against heat transmission, the compression will be of a type known as **adiabatic,** and the temperature of the gas will rise during compression because the mechanical work expended on the piston in obtaining the compression is converted into heat energy in the gas. On the other hand, if the cylinder is a good conductor of heat, and passes heat to the atmosphere as rapidly as it is received by the gas, the temperature at the end of compression may be the same as that at the beginning. In this isothermal compression the pressure at the end of compression is less than that of an equivalent adiabatic compression. In general, actual compressions are neither strictly adiabatic nor isothermal. (See **Air Compression, Compression Ratio, Polytropic.**)

In structural engineering compression is used to denote the type of stress which causes the fibers of a member to compress. (F.T.M.)

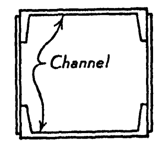
COMPRESSION MEMBER. Any member of a structure which is subjected to a primary compressive **stress** is called a **compression** member. The analysis or design is the same as that for a **column.**

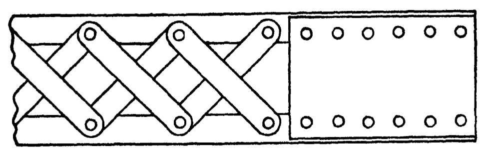
When the member consists of two or more separate elements, known as ribs, the parts are connected to produce unity of action and also to prevent excessive distortion during fabrication, shipping or erection. Tie plates and lacing are used for this purpose. The tie plates, also called stay plates or batten plates, which are rectangular in shape are placed at the ends of the member and at intermediate points where the lacing is interrupted. The lacing bars, also known as lattice bars, are plates, angles or channels placed at an angle to the longitudinal axis of the member. Lacing may be single or double as shown in the accompanying illustration of a

compression member made up of two channels which are rolled steel sections. Single lacing should make an angle of not less than 60° with the longitudinal axis of the



Single Lacing





Double Lacing

member. The angle for double lacing should be not less than 45°. The purpose of these minimum angles is to reduce the buckling tendency of the individual segments. (C.W.C.)

COMPRESSION RATIO. Ratio of Expansion.

COMPRESSION SPRING. Springs.

COMPRESSOR, VOLUME. In amplitude **modulation** systems of **radio communication** the amount of intelligence volume which can be modulated upon the **carrier** is limited to an amount which will give 100% modulation. Since the percentage of modulation depends directly upon the volume of the sound, it follows that, in order not to exceed the allowable modulation on very loud sounds, the percentage on most sounds will be rather low. Since the maximum use is made of the power and a higher signal to noise ratio is obtained for high degrees of modulation it is very desirable to keep the level of modulation as high as possible. To do this the volume range of the original sound is compressed into a much smaller range. Thus, while a symphony orchestra may have a volume range of 100–110 **db.**, the range is compressed to about 40 db. for broadcast purposes. In recordings the maximum volume which may be recorded is limited by the thickness of the groove walls so the volume range is reduced here also. An **expander** may be used in the reproducing system of the radio circuit or the phonograph to restore the original range. (L.R.Q.)

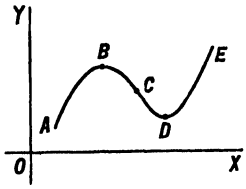
COMPTON EFFECT. The well-known increase in wavelength of **x-rays** scattered by the **electrons** of the lighter **atoms**. Professor A. H. Compton found in 1923 that when a beam of homogeneous x-rays enters carbon, for example, and is scattered at various angles θ with the incident direction, the wavelength of the scattered radiation, in angstroms, exceeds that of the incident by $0.0243(1 - \cos\theta)$. This he explained as due to collisions of the x-ray quanta with free electrons in the carbon, assuming conservation of momentum and conservation of energy as in ordinary elastic **collision.** The quantum is in general deflected obliquely (at angle θ), while the electron moves off in another direction, taking part of the energy $h\nu$ of the quantum. This lowering of the quantum energy, when the proper relativistic formulae for momentum and kinetic energy are used, corresponds accurately with the reduction in frequency and increase in wavelength actually observed.

The recoiling electrons were later detected by Professor C. T. R. Wilson by means of the cloud tracks which they produce in water vapor, and the speed of these electrons agrees exactly with Compton's analysis. The whole phenomenon, as interpreted by Compton, is a most striking confirmation of the **quantum theory** of radiant energy. (L.D.W.)

CONCATENATION. Variable speed control is more of a problem in a-c **motors** than it is in motors operating on d c. The wound-rotor motors, the speed of which is controllable by insertion of resistance in the rotor circuit, nevertheless suffer from the disadvantage of losses occasioned by conversion of electrical energy into heat in the resistors. A method of speed reduction without heating loss frequently used in railway service is known as concatenation. This form of connection is also called cascade control. Concatenation may be employed when there are two wound-rotor induction motors mounted on the same shaft, e.g., on the axle of a rail truck. Full power output is obtained, of course, when both motors are drawing current directly from the supply, and all external rotor resistance is short-circuited. Approximately half-speed operating conditions are obtainable if the rotor circuit of one motor is connected to the stator of the second motor. The stator, or armature winding of the second motor, imposes a resistance in the rotor circuit of the first motor, which reduces the rotor current and the power delivered by the first motor. This motor operates at half-speed and supplies the second motor with current the frequency of which is one-half of the frequency of the main supply. The rotor of the second motor will operate in the short-circuited state. Now as the speed of the motors decreases somewhat below half-normal synchronous speeds, the frequency of the current delivered by the rotor and the first motor rises somewhat over the half-speed point, and increases the magnetic slipping of the second motor, which is then receiving current at a frequency higher than half that on the supply mains, and is operating at slightly less than one-half normal synchronous speeds. The result is an increase of torque in the second machine, which will increase the speed until the decrease of frequency in the first machine's rotor circuit will cause the torque of the second motor to fall off to the value which will just maintain half-speed in the face of load conditions. (F.T.M., L.R.Q.)

CONCAVITY AND CONVEXITY OF A PLANE CURVE. Consider a curve whose equation in **rectangular coordinates** is $y = f(x)$. A tangent drawn to the curve will turn clockwise as the point of tangency moves from A to C, and counterclockwise as the point

moves from C to E. The curve from A to C is called concave downward and from C to E concave upward; the point C is called a point of inflection. At a point of inflection the curve changes from concave upward to concave downward, or vice versa.



A curve whose equation is $y = f(x)$ is concave downward at points where $f''(x)$ (i.e., d^2y/dx^2) is negative, and is concave upward where $f''(x)$ is positive; if $f''(x) = 0$ at $x = x_0$ and if $f''(x)$ changes sign as x increases through x_0, then the curve has a point of inflection at $x = x_0$. (L.L.S.)

CONCENTRATION. Concentration is the amount of a given substance in a stated weight or volume of material. The most commonly used method of expressing concentration is by stating the percentage, that is, parts by weight of the given substance in 100 parts by weight of the stated material. There are settled exceptions to this method of expressing concentration, and the units used should be carefully recorded or observed according as the reader is operator or reader respectively. Ethyl alcohol, in water mixtures, is commonly reported as a stated per cent by volume, where 50.0% by volume is equivalent to 42.47% by weight. (See **Ethyl Alcohol.**) Gases in a mixture are commonly reported by volume per cent, thus nitrogen in air 78.0% by volume (equivalent to 75.5% by weight). (See **Air.**)

The concentrations of substances in solution are expressed variously, thus, per cent by weight of the actual material stated, per cent by weight of a material calculated chemically from the actual material, grams of the actual material (or a material calculated chemically from this) per 100 milliliters of solution, gram mols (the formula weight taken in grams) of the actual material per liter of solution (this is molar or formal concentration and the abbreviations, M or F, respectively, are used to express it), gram equivalents (the equivalent weight taken in grams—see **Chemical Composition,** IV. Equivalents) of the actual material per liter of solution (this is normal concentration and the abbreviation, N, is used to express it).

Since the concentration is proportional in many individual cases to an easily determined physical constant, such as specific gravity (e.g., of solutions), index of refraction, specific rotatory power (e.g., sugar solutions, terpenes), such constants are frequently used to ascertain and express concentration data. (R.K.S.)

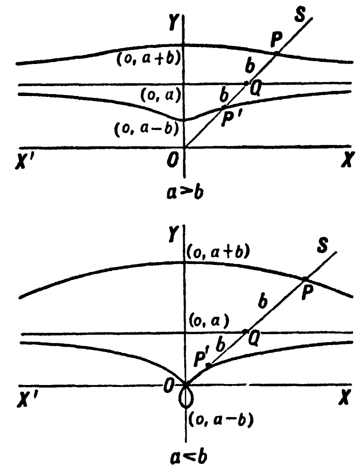
CONCH. Mollusca, Gasteropoda. Any of numerous species of large marine mollusks (**Mollusca**). The spiral shells have a long aperture, in many species beautifully colored. The shells are used for ornaments and as horns, and the animals are sometimes eaten. (A.W.L.)

CONCHIOLIN. A horny material which forms the outer layer of the shell mollusks (**Mollusca**). (A.W.L.)

CONCHOID OF NICOMEDES. The conchoid is a mathematical curve, first discussed by the ancient Greek mathematician Nicomedes. The name given to it is due to its supposed shell-like shape.

The conchoid may be defined geometrically as follows: With a set of rectangular axes, draw a line AB parallel to the X-axis, above it and at a distance a from it. Draw a secant line OS cutting AB at Q, and extend OQ in each direction a fixed distance b to points P and P'. As the secant line rotates about O, the points P and P' describe the conchoid.

In **polar coordinates,** the equation of the conchoid is $r = a \csc \theta \pm b$; in **rectangular coordinates,** the equation is $(x^2 + y^2)(y - a)^2 = b^2y^2$.



Conchoid.

The conchoid can be used for the "trisection of an angle," also to "duplicate a cube." (L.L.S.)

CONCHOLOGY. The study of molluscan shells. The word is sometimes applied to the study of mollusks generally but this field is more accurately called malacology. (A.W.L.)

CONCRETE. Concrete is a mixture of fine and coarse aggregates firmly bound into a monolithic mass by a cementing agent. The cement ordinarily employed for concrete is the standard Portland cement. The aggregates are sand and crushed stone or gravel. Crushed slag or cinders are used in special kinds of concrete. The formation of concrete can be thought of as a process in which the voids between the particles of coarse aggregate are filled by the fine aggregate, and the whole is cemented together by the binding action of the cement. The nature of Portland cement in this respect is described under **cement.**

Due to its strength, permanency, and low cost, concrete is one of the most important building materials employed in modern construction. It is widely used for **foundations** of all types, buildings, **bridges, dams, retaining walls, highways,** and other purposes too numerous to mention. However, the success of concrete in meeting any particular set of conditions, depends upon the proper correlation of many factors bearing on the selection and mixing of the materials, the placing of the concrete, and the original design. Concrete is strong in compression, but relatively weak in tension. Therefore structures in which the concrete is likely to be in **tension** must be reinforced with steel rods, which carry the tension and relieve the concrete of tensile stress. The design of plain and **reinforced concrete** structures has been placed upon a semi-rational technical basis. The uniformity of commercial cement enables the engineer to design an economical concrete structure—one having a minimum of unused excess strength. For strong permanent concrete, the aggregates should be clean, coarse, and well graded. River or coarse sand is better than pit sand, and should always be used where possible. The table on page 370 gives typical concrete mixes, with the characteristics of each.

This table is suitable for preliminary estimates or for small amounts of concrete, but it should be remembered that research and development in the science of concrete proportioning have advanced to the point where little short of a laboratory analysis can establish the best and most economical mix for a given condition. Type and gradation of aggregate, moisture content of the sand, and water-cement ratio are typical factors taken into account

in a complete analysis for the specification of large amounts of concrete work.

Concrete should be transported rapidly from the mixer to the forms, so that no initial set will have occurred before the concrete is placed in its final position. It is necessary to place concrete in the forms with care to prevent segregation of the lighter and heavier parts. This precludes dropping the concrete into place from any height. After the "green" concrete has been poured, it should be cured, or hardened, slowly over a period of about a week, during which time it should be protected from vibration, freezing, and a too-rapid rate of drying out. Strengths of concrete are usually classified on the basis of 28-day strength. Most of its strength will be acquired in this time but there is a slow increase in strength for a much longer period thereafter. (F.T.M.)

CONCRETION. Used in **petrology** and **geology** to designate spheroidal or discoidal aggregates formed by the secretion of silica, calcium carbonate, gypsum, or other chemical compounds around an original nucleus. (See also **Oölites.**) (R.M.F.)

CONCURRENT FORCES. Statics.

CONCUSSION. Concussion of the brain is a loose term used to describe certain events following a blow on the head. These consist of momentary loss of consciousness and general cessation of physiologic processes; the pulse is imperceptible, respirations cease, and there is no response to sensory stimuli. Recovery takes place rapidly. The patient regains consciousness and has no recollection of the blow. There is no satisfactory explanation of the pathologic physiology of concussion. Death rarely follows simple concussion and, when it does, gross changes in the brain are not found. (D.M.H.)

CONDENSATE. A liquid in the vapor state may be reduced to the liquid by removal of such portion of the latent heat of evaporation as it may contain. The act is called condensation, and the liquid is condensate. It is the property of vapors that the condensate is dense as compared to the vapor, which, in condensing, formed it; that is, there is considerable shrinkage of volume upon a reversion to the liquid state. The thermal condition of the condensate immediately upon formation is that of saturated liquid at the temperature of vapor. In other words, it has the temperature of the heat of liquid corresponding to saturation conditions at the vapor pressure. (F.T.M.)

CONDENSATION IN THE ATMOSPHERE. Clouds and precipitation are visible evidence that water vapor in the atmosphere condenses into liquid and solid water. Moisture in cloud form may be re-evaporated into the air, but rain, snow, and allied forms of precipitation actively lessen the total water content. This moisture loss by precipitation, considering the world at large, is replaced by equivalent evaporation of moisture into the atmosphere.

Nuclei upon which condensation can take place are absolutely necessary. Non-ionized and pollution-free air will become up to 400% supersaturated before condensation occurs. It also is known that clouds sometimes form before air becomes 100% saturated. Nuclei upon which condensation begins at the approach toward saturation are highly hygroscopic and encourage condensation. Minute salt crystals, primarily **sodium, magnesium** and **calcium** chlorides, carbonates, and sulfates, smoke particles, and ions serve as condensation nuclei. Lowering of the temperature of air below its dew point, or adding water vapor beyond the holding capacity of the air, is a second requirement for the formation of clouds. At high temperatures, air is able to hold up to 3% water vapor before becoming saturated but, at low temperatures, this amount may be as low as .01%. When air is cooled, therefore, it slowly loses its capacity to hold water vapor and that excess vapor condenses into cloud droplets (or ice crystals). Cooling is achieved in nature by one of four methods.

1. Cooling occurs by contact with surfaces cooler than the air. If clouds or precipitation are to result from this type of cooling, it is necessary that cooling proceed beyond the dew point of the air in question. Contact cooling is effective in forming fogs, dew, or hoarfrost, but as to precipitation, causes only drizzle.

2. Cooling occurs by lateral mixing of one air parcel with another at a lower temperature. The cooler parcel, however, is warmed somewhat. Lateral mixing is virtually noneffective in forming any extensive clouds, fogs, and does not cause precipitation.

3. When a layer of air having a lapse rate less than the adiabatic rate is mixed vertically, the top of the layer is cooled and the base warmed. This transfer of heat results from the establishment of an adiabatic lapse rate in the thoroughly mixed layer in contrast to its previously nonadiabatic rate. Cooling at the top of the layer, if there is sufficient water vapor present, will produce a cloud layer and may cause some small amounts of precipitation. Vertical mixing, however, is not the cause for more than slight amounts of precipitation even though it is the cause for considerable cloudiness.

4. Lifting of whole layers of air or parcels of air causes excessive cooling; cooling in turn causes cloudiness and precipitation. Lifted layers and parcels of air cause nearly all precipitation. Lifting occurs on windward sides of sloping terrain, along frontal surfaces, and in convection currents; these three taken together are the real causes of the world's precipitation.

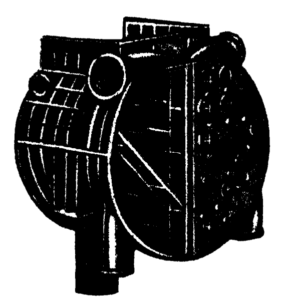
Lifted particles or layers of air while unsaturated, cool dry-adiabatically until the temperature and dew point coincide. The level at which the temperature and dew point become the same is known as the lifting condensation level because it is at this level that condensation into cloud droplets or ice crystals occurs. Condensation levels depend on the temperature and dew point of the lifted air, being high for dry air and low for nearly saturated air. (P.E.K.)

CONDENSATION PUMP. Air Pumps.

CONDENSER, ELECTRICAL. An electrical condenser is an arrangement of conductors and **dielectrics** used to secure an appreciable capacitance, sometimes

one of specified value. The essential feature of all condensers is a system of two or more conductors, separated by layers of dielectric. The potential difference between the conductors, when charged, is limited by the electric polarization in the dielectric. This makes it possible to accumulate large charges at comparatively small voltages. The oldest form of condenser is the **Leyden jar,** still often used where heavy electric discharges are desired. Many modern condensers consist of alternate metal and dielectric plates or sheets, sometimes of metal foil and paraffin paper strips rolled in a compact bundle. Condensers in which the dielectric is air, usually of adjustable capacitance, are much used in radio and oscillatory circuits. Standard condensers, of accurately known capacitance, are employed in electrical measurements. The capacitance of a condenser depends upon the total area a and the thickness d of the dielectric and upon its dielectric constant k. If the dimensions are in centimeters, the capacitance for a condenser of flat plates is approximately given in electrostatic units by the formula $C = ka/4\pi d$ and in microfarads by $C = 8.84 \times 10^{-8}\, ka/d$. Thus if there are 21 metal plates 10 cm. sq., separated by 20 sheets of mica 0.01 cm. thick and of dielectric constant 6, the capacitance is about 0.106 microfarads. The capacitance is often made adjustable by varying the distance d or by arranging the plates to move past one another so as to vary the area a of dielectric subject to the electric field between them. (F.T.M., L.D.W., L.R.Q.)

CONDENSER, STEAM. A steam or vapor condenser is a device which performs the operation of reducing a vapor to a liquid through the extraction from it of the heat of evaporation it may contain. Industry and research use the condenser extensively to recover a liquid which has been separated from another liquid of higher boiling point or from impurities by the evaporation method. The condenser is an important part of the modern steam power cycle. The purpose of the steam condenser is to lower the back pressure on the prime



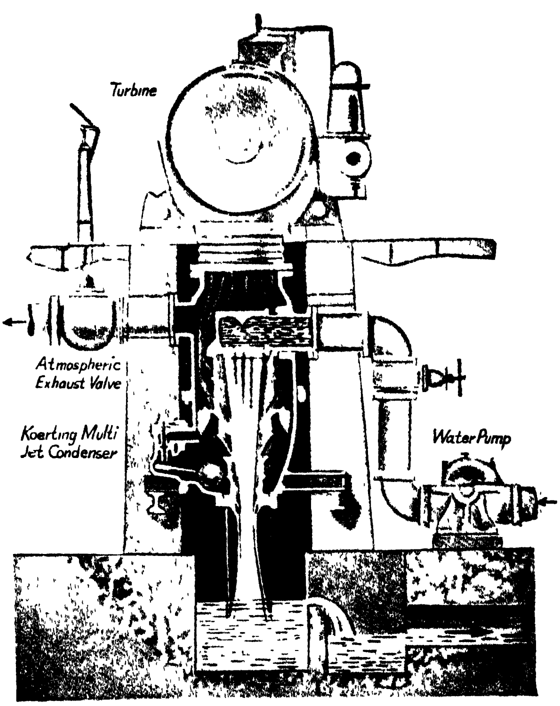
C. H. Wheeler Radial-Flow Condenser. End view with half of water box cover removed and cross-section at middle.

mover, allowing the steam a larger pressure and temperature drop, thereby increasing both efficiency and capacity. A secondary purpose may be the supply of quantities of warm water or the collection of condensate for boiler feed water. Condensers are applicable to both engines and turbines, though especially to the latter because its thermodynamic advantages occur chiefly in the low-pressure range. Engines are ordinarily operated condensing up to 26″ Hg vacuum and turbines up to 29.5″. Size of the equipment required to create the necessary piston displacement is the limiting factor in reduction of engine back-pressure. Furthermore, the larger the temperature difference between inlet and exhaust steam in the ordinary counter-flow engine, the larger the initial condensation loss. Economies effected by condensing operation may be from 10% to 30% higher than for non-condensing.

Condensers can be divided into *contact* and *surface* types. Steam and condensing water are intimately mixed in the contact type. Then the condensate and condensing water are withdrawn thoroughly mixed together. A dividing surface is interposed between steam and water in the surface condenser. Heat is transferred through this partition surface at rates varying from 300 to 800 B.T.U. per sq. ft. per hour per degree Fahrenheit. The steam and condensing water never come into direct contact and are withdrawn from the condenser separately. The dividing surface is ordinarily a tube with condensing water circulating inside and steam outside.

The contact condensers (jet condensers) may be further subdivided into those from which the water is extracted directly by pumps, those from which it is forced by the ejector action of a high-velocity water jet, and those from which it flows by virtue of a head of water maintained in a long tail pipe. Elements of the jet condenser are: (1) nozzles or distributors for the condensing water, (2) steam inlet, (3) mixing chamber, (4) hotwell, (5) in some cases, a diffusing chamber or a tail pipe.

Surface condensers are classified as horizontal or vertical by the position of their tubes. They are single-pass or double-pass according to whether the water passes the length of the condenser once or twice. Three-pass condensers are infrequently used at present. They are also classified upon a basis of the shape of the shell, as, for instance, cylindrical, heart-shaped, U-shaped, oval; and upon the location of the air-cooling surface—internal or external. The elements of the surface condenser are (1) cooling surface for both air and steam, usually ¾, ⅞, or 1-in. copper alloy tubes from 10 to 25 ft. long, (2) tube sheets into which the tubes are expanded or packed, (3) intermediate tube supports (sheets bored similar to the tube sheets but in which the tubes



Typical arrangement of multi-jet condenser under turbine.

fit loosely), (4) water boxes provided with circulating water connections and enclosing the space furnished for water flow to and from the tubes, (5) steam inlet, air and condensate outlet, (6) hotwell in which the condensate collects (in some plants deaeration of the condensate is done in a deaerating hotwell, while in a few cases reheating hotwells are installed to offset undercooling of the condensate), (7) condenser shell enclosing and supporting the other elements.

Heat transfer action in a surface condenser is hindered by the presence of non-condensable gases which mix with the film of condensate on the tube surface. The sources of air and other non-condensable gas leakage are numerous. Some may come over with the boiler steam, or leak in through turbine packing gland or exhaust nozzle connection. Air leakage will seriously affect the heat transfer and every effort is made to minimize it.

The auxiliaries required for condensers can be arranged under two heads: first, those connected with the flow of water; second, those connected with the vacuum. The condensate pump serving a large condenser is always of the centrifugal type but reciprocating pumps may be used for small surface condensers and jet condensers. The head on it is the vacuum plus friction of the piping to the surge tank plus the velocity head plus the difference in elevation between the discharge to the surge tank and the condenser hotwell.

A high-vacuum surface condenser requires around a hundred pounds of water per pound of steam condensed. Supply of circulating water is often a deciding factor in station location and a limiting factor in extension of existing plants. These large amounts of circulating water make the circulating water system of considerable importance. In case of limited supply of circulating water it may be necessary to resort to cooling towers and ponds to cool the water for recirculation.

The auxiliary equipment having to do with vacuum includes the vacuum pump, atmospheric relief, vacuum breaker, and manometer. Vacuum pumps may be classified as reciprocating, rotary, or ejector types. The reciprocating type, similar in principle to the air compressor, becomes inconveniently large for other than small or low-vacuum condensers. The steam jet ejector is a widely used air pump, especially on large condensers. It can be used with both the jet and surface types. When the heat liberated by condensing the ejector exhaust is recovered in the feed water the ejector becomes a compact, efficient, and simple machine for exhausting the non-condensable gases. Having no moving parts and requiring little attention, the ejector can be located in inaccessible positions. Its first cost compares favorably with other types of exhausters. (F.T.M.)

CONDITIONED REFLEX. **Reflex.**

CONDOR. Aves, Falconiformes. A large **vulture** of the Andes of Peru and Chile. This bird reaches a length of more than 4′ and a wing expanse of 10′, and is among the largest birds now existing. A smaller condor has been reported from Ecuador and the California vulture, *Gymnogyps californianus,* is also called a condor. The last species occurs in Lower California, southern California, and east to Arizona, living in the mountains. It is sometimes larger than the condor of South America. All of the condors eat carrion. (A.W.L.)

CONDUCTANCE. **Admittance.**

CONDUCTION. **Electric Conduction; Thermal Conduction.**

CONDUCTIVITY. For conductivity of electricity, see **Resistance**; for conductivity of heat, see **Thermal Conductivity.**

In biology, conductivity is a fundamental property of living matter through which impulses generated by some form of stimulus are transmitted from one part to another of the individual body. It attains its highest expression in the nervous tissue of animals. Here impulses set up by the reception of stimuli by sense organs travel through the nerve fibers and arouse other impulses in associated nervous structures or activate muscle fibers or other organs capable of appropriate action. A stimulus may also arise in the nervous system itself, conditioned by memory, to bring about some action.

The nature of conduction in living substance is not completely understood. In nerve fibers the simultaneous occurrence of electrical and chemical changes during the passage of impulses has been demonstrated. (F.T.M., A.W.L.)

CONDUCTOR. A material which, when placed between terminals having a difference of electrical potential, will readily permit the passage of an electric current, is an electrical conductor. Different materials have different degrees of conductivity, and their effectiveness in this respect is computed as the **conductivity.** The best conductors are the metals, such as silver, copper, aluminum, platinum, mercury, etc., but non-metallic substances such as carbon, saline solutions, and moist earth also are sufficiently conductive so that this property becomes of significance under certain circumstances. By virtue of their cost-conductivity characteristic, copper and aluminum are the most widely used conductors. They will usually be found as wires or **buses.** Copper is used more commonly than aluminum, the use of which is still largely confined to high-voltage transmission lines, where its lighter weight is of definite advantage. Steel as a conductor is inferior to the other two materials mentioned, but its greater strength and resistance to wear have led to its adoption as a conductor of special purposes, such as that of third rail service on electrified railways, and as an inner core of copper or aluminum cables. The resistance of a conductor is its resistivity multiplied by its length and divided by its cross-sectional area. When the length is expressed in feet, and the area in **circular mils,** the resistivity of aluminum is 17.48; of copper, 10.35; and of iron, 58. This property varies with the temperature of the conductor, and the constants quoted apply only at 20° C. (F.T.M., L.R.Q.)

CONDUIT. In engineering, a conduit is ordinarily taken to be a means for holding and enclosing electrical wires. The most widely used electrical conduit is the rigid iron conduit. Iron conduit is simply wrought-steel pipe well enameled on the inside for the protection of the wires, which are drawn into the conduit. Fiber and brass conduits are used when all wires of an a-c circuit cannot be run in one conduit, for the installation of one conductor in an iron conduit would greatly increase the inductance of the line and would also make of the body of the conduit a circuit in which would circulate currents similar to the core loss of a transformer. The reason for the popularity of a rigid iron conduit is that it is fire- and moisture-proof, reliable, and mechanically strong. It can be laid rapidly by methods similar to those employed in plumbing.

Wires are installed in a conduit as follows: A fish tape or wire, a tempered steel wire of rectangular cross-section, is pushed through the conduit until it appears at the farther end. A draw line is then attached to it and by withdrawing the fish tape, the line is drawn through the conduit. The wires are in turn attached to the draw line and drawn into position. This method of installation requires (1) that the conduit interior be smooth and uninterrupted, (2) that the bends be of long radius and limited in number. If the conduit were not smooth internally there might be difficulty in pushing the fish tape through it, and the roughness would doubtless damage the insulation on wires being drawn in. When conduit is cut and threaded the ends should be reamed to remove burrs. The ends should be set up well into the coupling and should be leaded unless in a dry location. Ordinary pipe elbows are not used in conduit wiring. The pipe itself is bent to a long radius or long radius elbows are used. Due to the snubbing action of bends on wire being drawn through the conduit, not more than four equivalent 90° bends are permitted between pulling points, and many prefer to limit the number to

three. In size, conduits smaller than ½-in. iron pipe size are not to be used, while conduits larger than 4-in. size are seldom required. Fiber ducts or tunnels are favored over the large iron conduit. Manufacturers have developed, in place of ordinary pipe elbows, tees, etc., lines of special conduit fittings designed to satisfy all requirements for outlets, junctions, etc. (F.T.M., L.R.Q.)

CONDYLARTHS. **Paleocene.**

CONDYLE. A rounded prominence on a bone, associated with a joint. (A.W.L.)

CONE. A cone is one of the simple and basic type forms of geometric solid.

The surface generated by a straight line turning around one of its points and intersecting a given curve is called a conical surface, and the solid bounded by such a surface and a plane cutting it is called a cone.

The volume of a cone is equal to ⅓ the product of the area of the base by the altitude. For a right circular cone of altitude h, radius of base r and slant height s, the volume is given by $V = \frac{1}{3}\pi r^2 h$, and the lateral area by $A = \pi rs$.

A frustum of a cone is the portion of a cone between two parallel planes. The volume of a frustum of a cone is given by the formula

$$V = \tfrac{1}{3}h(A_1 + A_2 + \sqrt{A_1 A_2}),$$

where h is the altitude of the frustum (perpendicular distance between cutting planes or bases), and A_1 and A_2 are the areas of the bases.

The **locus** of a second-degree equation in x, y, z which is **homogeneous** in these variables is a conical surface with vertex at the origin.

The standard equation of a cone is

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 0$$

(L.L.S.)

CONE OF SILENCE. **Radio Range.**

CONE, WIND. **Wind Indicator.**

CONE-IN-CONE STRUCTURE. Probably a **concretionary** structure frequently observed in **limestones, dolomites** and other **sedimentary** rocks which originated as fine-grained sediments. As the term suggests the structure is formed by a series of concentric cones, the result of radial **crystallization** around a common axis, probably due to differential pressures. (R.M.F.)

CONFIDENCE LIMITS. Confidence limits are intervals, different for each **sample**, set up in successive samples, which cover the **population parameter** a certain proportion of times, called the confidence coefficient. Usually the confidence coefficient is chosen as .95, .99, or .995, depending on the particular level of confidence desired. When the confidence coefficient is increased, the confidence interval becomes larger. It should be realized that each sample gives another confidence interval and that after a confidence interval is determined that either the population parameter is covered by the interval or it lies outside the interval. To find confidence intervals the distribution of the **statistic** must be known. Confidence intervals have been obtained in cases where the statistic is distributed according to **Student's t distribution**, in the **Bernoulli probability function** for p, in the **Poisson probability function** for m, and for many other population parameters. Confidence intervals should not be confused with **probability limits** within which a chance **variable** lies a certain proportion of the time. A population parameter is a constant and does not vary from sample to sample. A confidence interval may be considered as the estimate of a population parameter by an interval instead of by a point. (L.A.A.)

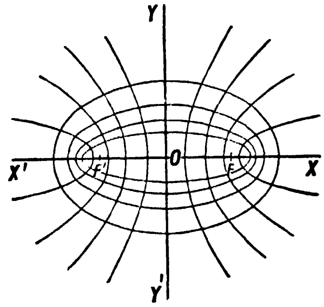
CONFLUENT. Used by geologists and physiographers to designate a stream that unites with another; especially applied to streams nearly equal in size. (R.M.F.)

CONFOCAL CONICS. If two **central conics** have the same foci, they are said to be confocal.

The equation

$$\frac{x^2}{a^2 + k} + \frac{y^2}{b^2 + k} = 1 (a > b),$$

where k is an arbitrary constant, represents the system of confocal conics consisting of the **ellipses** and **hyperbolas** whose common foci are at the points $(\pm\sqrt{a^2 - b^2}, 0)$. When $k > -b^2$, the conic is an ellipse, when k is between $-a^2$ and $-b^2$, the conic is a hyperbola.



Confocal conics.

Through any given point there pass just one ellipse and just one hyperbola of the confocal system. The two conics of the system which pass through a given point intersect at right angles. (L.L.S.)

CONFOCAL QUADRICS. Confocal quadrics are geometric surfaces having a common focus.

The system of surfaces represented by the equation

$$\frac{x^2}{a^2 + k} + \frac{y^2}{b^2 + k} + \frac{z^2}{c^2 + k} = 1,$$

in which k is an arbitrary constant, is called a system of confocal quadrics. The principal sections of the system (sections by the coordinate planes) are **confocal conics.**

Through every point there pass three quadrics of the system, namely, an **ellipsoid**, an **hyperboloid of one sheet** and an **hyperboloid of two sheets.** These three surfaces are orthogonal, that is, their **tangent planes** are mutually perpendicular. (L.L.S.)

CONFORMABLE CONTACT. Used by **stratigraphers** and **structural** geologists to designate strata in parallel contact. (See also **Unconformity.**) (R.M.F.)

CONGENITAL. A condition or deformity that exists at or before birth. (D.M.H.)

CONGER. Pisces, Teleostei. Large marine **eels**, *Leptocephalus*, with sharp cutting teeth. They are widely distributed. Also applied to the **Congo snake.** (A.W.L.)

CONGLOMERATE. Conglomerate, called in older writings "pudding-stone," consists of aggregates of gravel or pebbles with a matrix of sand and cement. The proportion of pebbles and matrix may vary considerably both as to amount and actual or relative size of the component material. The common cementing materials are silica, **calcite**, and iron oxide.

Consolidated glacial debris called **tillite**, may consist of boulders of considerable size in an heterogeneous mixture of pebbles, clay and sand. (R.M.F.)

CONGO RED. Dyes.

CONGO SNAKE. Amphibia, Urodela. A slender aquatic **salamander**, ***Amphiuma means***, of the southeastern states. The legs are very small, hence the animal is much like a snake in appearance. Also called the blind eel, Congo eel, and conger. (A.W.L.)

CONIC SECTIONS. The curve of intersection of a right circular **cone** by any plane is called a conic section or simply a conic. If the cutting plane does not pass

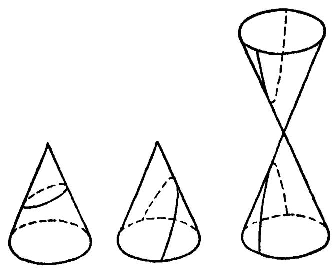


Fig. 1 *Ellipse* *Fig. 2* *Parabola* *Fig. 3* *Hyperbola*

Sections of a cone.

through the vortex of the cone, the conic section belongs to one of the following three types.

1. If the cutting plane cuts all the elements of one nappe of the cone, the section is an **ellipse**, including the **circle** as a special case.
2. If the cutting plane is parallel to an element of the cone, the section is called a **parabola.**
3. If the cutting plane cuts both nappes of the cone, the section is called a **hyperbola.**

The conic sections were discussed by the ancient Greek mathematicians.

When a variable point moves so that its distance from a given fixed point to its distance from a given fixed line has a constant **ratio**, the **locus** is a conic. The given fixed point is called the focus, the given fixed line the directrix, and the ratio of distances the eccentricity e of the conic.

If $e = 1$, the conic is a parabola; if $e < 1$, the conic is an ellipse; if $e > 1$, the conic is a hyperbola.

The ellipse and hyperbola are called central conics, since they each have a center of symmetry.

The general equation of the second degree, in **rectangular coordinates,**

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0,$$

represents:

(1) a hyperbola if $h^2 - ab > 0$,
(2) a parabola if $h^2 - ab = 0$,
(3) an ellipse if $h^2 - ab < 0$;

it represents a proper conic (non-degenerate) if

$$\Delta = \begin{vmatrix} a & h & g \\ h & b & f \\ g & f & c \end{vmatrix} \neq 0.$$

If $\Delta = 0$, the equation is represented by a pair of straight lines. An equation of the form $ax^2 + by^2 + 2gx + 2fy + c = 0$ will represent an ellipse if a and b are of the same sign, and a hyperbola if a and b are of opposite signs.

The equation of a conic in **polar coordinates** is

$$r = \frac{ep}{1 - e\cos\theta},$$

where e is the eccentricity and p is the distance from the focus to the directrix, if the pole is at the focus and the polar axis is perpendicular to the directrix.

The equation of the **tangent** to the conic

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$$

at the point (x_1, y_1) is

$$ax_1x + h(x_1y + xy_1) + by_1y + g(x + x_1) + f(y + y_1) + c = 0$$

The tangents and **normals** to conics have many interesting properties. A few of them will be mentioned.

The tangent and normal to an ellipse bisect, respectively, the external and internal angles formed by the focal radii of the point of contact. (See Fig. 4.) There is a similar theorem for the hyperbola.

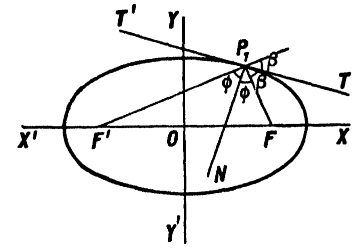

Fig. 4. Reflecting property of ellipse.

This theorem has an interesting application to drawing a tangent and normal to an ellipse at a given point on the curve.

The phenomenon observed in "whispering galleries" depends on this property. Thus, in Fig. 5, let the

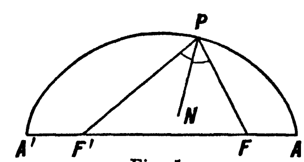

Fig. 5.

elliptic arc $A'PA$ be a vertical section of such a gallery. The waves of sound from a voice at focus F will, after meeting the ceiling of the gallery at P, be reflected in the direction PF'. The law of reflection of sound waves is that the angles of incidence and reflection are equal. Hence sound waves emanating from F in all directions will converge at F'. A whisper at F, which would not carry over the distance FF', might consequently, through reflection, be audible at F'.

The tangent and normal to a parabola bisect respectively the internal and external angles formed by the focal radius of the point and the line through that point parallel to the axis. (See Fig. 6.)

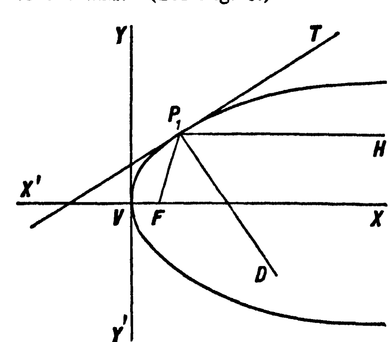

Fig. 6.

This can be applied to the construction with ruler and compass of the tangent and normal to a parabola.

The principle of parabolic reflectors depends upon this property. The reflecting surface of such a reflector is obtained by revolving a parabolic arc about its axis. If now a light be placed at the focus, the rays of light

which meet the surface at P_1 in the figure will be reflected in a direction making with the normal P_1D an angle equal to the angle FP_1D. But this direction is, by the above property, parallel to the X-axis (axis of parabola). Reflecting telescopes operate on this principle. (L.L.S.)

CONICAL PROJECTIONS. The term conical projection is applied to any one of that class of **map projections** in which the surface of the **earth** is projected from a point within the earth to the surface of one or more **cones**, and then developed on a plane.

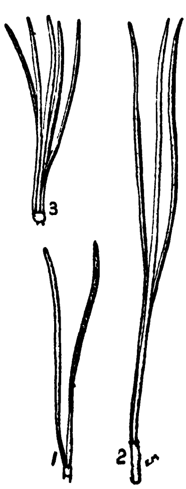
In the simple conical projection a cone is placed tangent to the surface of the earth along the central parallel of **latitude** for the region to be mapped. The surface features are then projected onto the cone, the cone is cut along that element which represents the meridian of **longitude** 180° from the central longitude of the mapped region, and the cone is rolled out on a plane. The resulting **graticule** will show parallels of latitude as circles concentric at the pole of rotation (usually outside the limits of the map), and meridians of longitude as straight lines converging on the pole.

Along parallels of latitude and along the central meridian the scale of distance is uniform. The map is not conformal except close to the central parallel and the distortion of shape increases rapidly with distance from that parallel. The simple conical projection is sometimes used for maps of small countries. For relatively large areas the **polyconic** and **Lambert** projections are preferable conical projections. (W.K.G.)

CONICAL SPRING. **Springs.**

CONIDIA. A conidium is an asexual spore, characteristic of many **fungi**. Commonly it is formed at the tip of a hyphal branch, which is called a conidiophore. Conidia may be one- to many-celled. (R.M.W.)

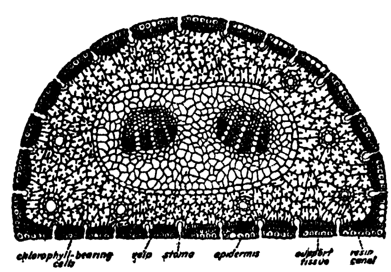
CONIFERS, OR CONIFERALES. This group contains some 400 of the 500 species of **gymnosperms**. It includes the dominant evergreen trees of the north temperate zone, as well as many tropical species. Conifers are at their best in regions where severe winters occur. Nearly all conifers are trees, often of great size, and may attain great age, as for example the redwoods of California and the Douglas firs of Washington and Oregon.



Leaf clusters from different species of pine. 1, *Pinus Murrayana;* 2, *Pinus ponderosa;* 3, *Pinus flexilis.*

While they are dominant plants in the northern forests of today, in Mesozoic times they were much more numerous and often of much greater size. The petrified forest of Arizona contains a fossil Gymnosperm, *Araucarioxylon arizonicum,* from the **Triassic** period. As recently as the **Miocene** age, coniferales were much more widely scattered than at present, species of Redwood and Cypress growing in regions as far north as Greenland; today they are found only in warmer climates and often in a very restricted range there. Though naturally restricted in habitat, many of them are easily introduced into new, often distant regions, where they thrive.

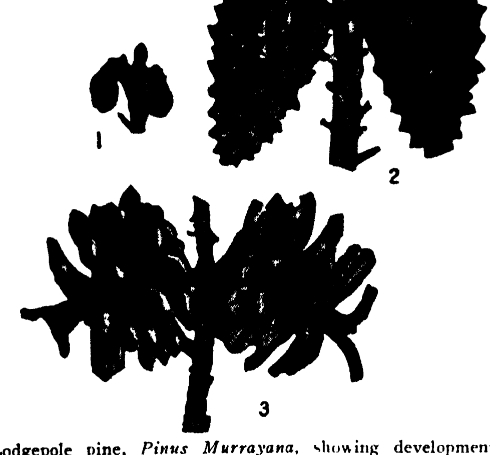
The plant body of the conifers varies from low straggling shrubs to large trees. The several parts of the plant also show great diversity. Nearly all of them have tall straight stems extending to the very top of the tree, and numerous lateral branches which are progressively shorter from bottom to top of the trees, which therefore have an attractive conical shape. In many species there is a central tap root extending deep into the ground, from which smaller lateral roots arise. In other species extensive lateral roots spread out near the surface of the ground. The leaves of conifers of the northern hemisphere are either slender and needle-shaped or short and scale-like. Those of the pines are formed in fascicles or bunches of 2–5 which grow from a very short lateral branch. In spruces and firs the leaves are borne singly around the stem. In white cedar and certain other conifers the leaves are reduced to short pointed scales which are formed in pairs of opposite sides of the stem, and are pressed tightly to it. In the southern hemisphere there are several conifers with broad leaves very similar in outward appearance to those of many angiosperms. The leaves of conifers have an epidermis of thick-walled cells which give stiffness to the leaves. The stomata are sunk deep in grooves. The chlorenchyma of the leaves, the cells containing the **chloroplasts,** is formed of cells the walls of which are curiously infolded. These cells surround the central vein, in which are found the **vascular** bundles. Some species have one, others two bundles in a leaf. In the chlorenchyma numerous resin canals are found. These are also present in the bark and in the wood of many gymnosperms. The leaves of most gymnosperms re-



Cross-section of a pine leaf.

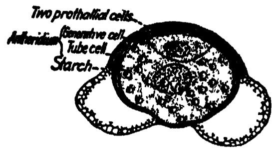
main on the tree from 2 to 5 or more years, and even, in some species, persist for as long as 20 years. Those of the larches are deciduous, falling in the autumn, and leaving the branches bare through the winter.

The reproductive structures of the conifers are the cones or strobili, which are of two kinds, staminate and ovulate cones. Usually these are found on the same tree, which is therefore **monoecious.** The **staminate** cones, too, often called the male cones, are small and short-



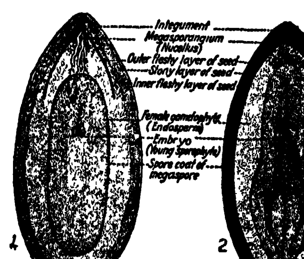
Lodgepole pine, *Pinus Murrayana,* showing development of ovulate strobili. 1, Pair of strobili shortly after pollination; 2, pair of strobili one year old; 3, pair of strobili two years old after the seeds have been shed.

lived. They are generally found in clusters near the tips of the branches. A staminate cone consists of a central axis and a series of spirally arranged microsporophylls. Each microsporophyll bears two pollen-sacs or microspororangia on its lower surface. Each microsporangium contains numerous cells called microspore mother cells which divide by meiosis to form



Austrian pine, *Pinus laricio.* Microspore developing into pollen grain. (*Chamberlain's Elements of Plant Science, McGraw-Hill Book Co., Inc.*)

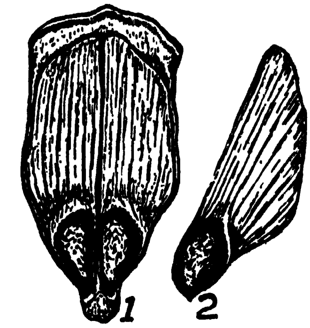
haploid microspores, or pollen grains, four from each microspore mother cell. The number of pollen grains produced is tremendous; often they are liberated from the sporangia in such quantities as to produce what are known as "sulfur showers," which cover the ground with a layer of yellow pollen, or cause the water of ponds to become turbid with the pollen grains. The



Development of pine seed. 1, two embryos have started and the suspensors have pressed one of them deep into the endosperm; 2, single mature embryo, its mate having failed to develop to maturity. (*Chamberlain's Elements of Plant Science, McGraw-Hill Book Co., Inc.*)

pollen is carried about by the wind, often to distances of many miles. The wall of a pollen grain is composed of two layers, an inner, called intine, and an outer, exine layer. In some conifers the outer layer is separate from the inner in two places, forming conspicuous balloon-like structures which presumably are an aid in keeping the pollen grain floating in the air. Even before shedding, the **nucleus** of the pollen grain has divided, so that the grain at the time of shedding contains three or more cells. All but one of these are very small and last but a short time before they disintegrate, leaving thin disk-like cells pressed against one side of the pollen grain. These small cells are usually called prothallial cells, and are thought to be vestiges of extensive vegetative tissue or earlier forms. The large cell of the pollen grain divides to form two, known as the generative and tube cells.

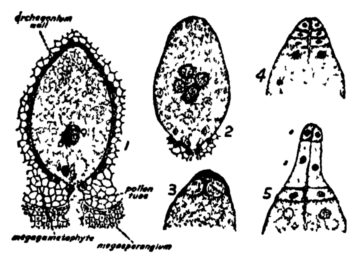
The ovulate cones require a much longer time than the staminate to reach maturity. Often they remain on the tree for many years. The structure of the ovulate cone varies in the different genera, and is the cause of much discussion in many cases. In the pines, the genus in which the development of the ovulate structure is best known, the cone is made up of numerous scales. On the upper surface of each scale there are two ovules. The greater part of each ovule is a mass of cells called the nucellus or megasporangium. This is surrounded by an integument, a tissue which does not completely enclose the nucellus, a small opening known as the micropyle being left. It is through this opening that the pollen grains reach the surface of the megasporangium. As the ovule develops, one or sometimes more of the cells in the nucellus becomes distinct from the other cells because of its larger size and denser protoplasm. This is the megaspore mother cell. It divides by meiosis to form a row of



1, megasporophyll and two seeds; 2, a single seed with wing. (*Curtis, Nature and Development of Plants, Henry Holt & Co.*)

four cells, one of which becomes the megaspore, the others degenerating. The single megaspore divides into many cells which form the female gametophyte or megagametophyte. At the end of the megagametophyte nearest the micropyle several **archegonia** develop. Each archegonium contains a single very large egg cell.

The pollen grain, carried by the wind, comes in contact with a small drop of fluid which has been secreted by cells in the region of the micropyle. As this evaporates the pollen grain is drawn down into the micropyle to the surface of the nucellus. There the pollen grain puts out a pollen tube which grows through the



Stages in the early development of a pine sporophyte. 1, fertilization; 2, zygote nucleus has divided into four nuclei which pass to the end of the sac farthest from the micropyle and divide again; 3 and 4, walls have formed between the nuclei; 5, suspensor cells (s) elongate, pushing pro-embryo cells (e) into the megagametophyte. (*Curtis, Nature and Development of Plants, Henry Holt & Co ; after Ferguson and Coulter and Chamberlain.*)

nucellus tissue until it reaches the tip of the megagametophyte. During this development a final division of the generative nucleus has occurred, and two male gametes or sperm nuclei are formed. When the tip of the tube reaches an archegonium these nuclei are discharged into the egg. One of the nuclei passes to the egg nucleus and fuses with it; the other disintegrates. The time required for the pollen tube to reach the egg varies greatly in different genera; in some, like the spruce and the hemlock, it is a matter of a few weeks; in others, like the pine, it is nearly a year.

The nucleus of the fertilized egg passes to the basal end, dividing twice, and forms a rosette of four nuclei. Each of these divides again, forming two tiers of four nuclei. Walls then begin to form, separating the apical tier from the other. Subsequent nuclear divisions increase the number of tiers to four, each composed of four cells. The apical tier presently divides and forms the **embryo**; the second tier, called the suspensor, elongates greatly, shoving the embryo down into the gametophyte tissue. There the embryo absorbs food substances from the tissues around it and matures.

The mature seed of a gymnosperm consists of a hard seed coat, developed from the integument, the nucellar tissue, and the embryo. The latter consists of a straight slender **hypocotyl** and two or more **cotyledons**, and a very small **epicotyl** or plumule. During its development this embryo has been surrounded by a mass of tissue called the **endosperm**, which is megagametophyte tissue.

The seeds of different conifers vary greatly in size. In some species of pine, they are large enough to be used as food for human beings. In the southwestern United States there are several species of pine which bear edible seeds. These are called piñon nuts, and are used in the same way as peanuts are. In southern Europe other species of pine yield edible seeds. One of these, called pignolea nuts, is frequently used in confectionery.

The conifers yield many other valuable products. The **wood** of many of them is extremely valuable, forming the principal timber used in construction work. Its use in this work is largely due to its composition. Each annual ring is composed of two distinct layers, an inner soft layer and an outer hard layer often much darker colored than the other; these give to the wood great strength and also flexibility, and allow easy driving of nails into the wood without splitting it. The wood is also used for **paper** pulp. **Turpentine** and **resin** are obtained from many of the conifers. **Amber** is a fossil resin coming from an extinct conifer. Many conifers are grown as ornamental trees, often in regions far from their natural habitat.

Several genera of conifers are well known for various reasons. Perhaps the best known are the Redwoods, two species of the genus *Sequoia,* which is found in California. *Sequoia gigantea,* the giant redwood, grows in scattered groves on the western slopes of the southern Sierra Nevada mountains in California. The trees may reach a height of 300′ and have massive trunks 12–36′ in diameter. Many of them are 3000 years old or more. Fortunately the wood of this species is a poor timber, so that they are reasonably safe from cutting for lumber. The other species, *Sequoia sempervirens,* grows north of San Francisco near the coast. It also is a tall tree, but more slender than the "big trees," averaging 15′ in diameter. It grows more rapidly, reaching maturity in 1000 years or less. Its soft red wood is an excellent timber and much used.

Another conifer native in the western United States is the Douglas Fir, *Pseudotsuga Douglasii.* This tree, like the redwood, attains great size, growing 300′ or more in height, and 6–10′ in diameter. It is a valuable timber tree.

A third conifer, the cedar of Lebanon, *Cedrus libanotica,* is an attractive tree with numerous spreading branches which grows 70–100′ tall and 5–7′ in diameter.

The Cypress, *Taxodium distichum,* is a tree of the wet lowlands of southern United States and Mexico. It is a large tree, often more than 100′ high and 4–6′ in diameter. When growing in wet swamps, erect woody protuberances known as cypress "knees" grow out from the roots. These have a long conical shape and may be several feet high. The wood of the cypress is soft, straight-grained, and has a peculiar somewhat unpleasant odor. The heartwood varies from red to very dark brown; the sapwood is light. The wood is very resistant to exposure to water, and also not liable to damage by insects. It is used in greenhouse construction, in making vats, and other containers for liquids, in furniture-making and for many other purposes requiring a soft, durable, non-shrinking wood. One of these trees, growing in southern Mexico, is very large and, while undoubtedly very old, is still sound. This is the "Big Tree of Tule," which has a trunk diameter of 50′.

Many species of Firs (*Abies*) and Pine (*Pinus*) also reach great size. But others are remarkable for their ability to endure adverse conditions and thrive. Under these conditions they may remain very small. Specimens of *Pinus Thunbergia,* for example, are much grown in cultivation by the Japanese, who give to them a bizarre yet very attractive shape, while keeping them very small. Some of these dwarf trees may be many years old and yet only a foot or less in height. Grown normally, it is an irregularly branched tree 100′ or more high and 6–7′ in diameter. Other conifers are also used by the Japanese in pot cultures and dwarf gardens (see **Paleobotany**). (R.M.W., B.S.M.)

Isolated tree of the Western Yellow Pine, *Pinus ponderosa.*

CONIINE. Alkaloids.

CONJUGATE FOCI. In photography the interdependent distances between object and lens and lens and image are known as the conjugate distances. As the distance from the object to the lens increases, that from the lens to the image decreases and vice versa.

The formula expressing the geometrical relation between these distances is:

$$\frac{1}{f} = \frac{1}{v} + \frac{1}{u}$$

where f is the focal length of the lens, v the lens-to-image distance and u the object-to-lens distance Thus:

$$u = \frac{f \times v}{v - f}$$

$$v = \frac{f \times u}{u - f}$$

$$f = \frac{u \times v}{u + v}$$

The ratio of the conjugate distances determines the scale of the image. Thus:

$$R = \frac{v}{u}$$

where R = the relative size of the image to the object and u and v are the object and image distances as before. When u is greater than v the object is larger than the image (reduction); when v is the greater then the image is larger than the object (enlargement).

Other formulae follow:

$$R = \frac{f}{u - f} \quad R = \frac{v - f}{f}$$

$$f = \frac{u \times R}{R + 1} \quad f = \frac{v}{R + 1}$$

$$u = \frac{v}{R} \quad u = \frac{f}{R} + f \quad u = v \times R \quad u = (R + 1) \times f$$

$$v = u \times R \quad v = (f \times R) + f \quad v = \frac{u}{R} \quad v = \frac{f}{R} + f$$

D = total image-to-object distance

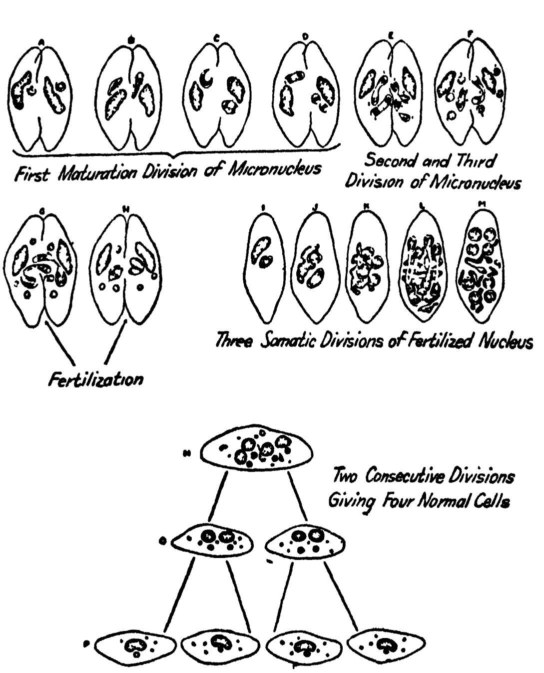
$$D = \frac{v \times (R + 1)}{R}$$

$$D = u \times (R + 1)$$

(C.B.N.)

CONJUGATE GEARING. Spur Gearing.

CONJUGATION. A process of interchange of nuclear material between two individual 1-celled animals. The cells come together in a close association and undergo nuclear divisions. One nuclear component of each passes over into the other conjugant and unites with a nuclear



Conjugation in *Paramecium caudatum.* (*After Calkins.*)

derivative of that individual to form a new nucleus. The completion of the process takes place after the separation of the two cells. It is equivalent to **fertilization.** (See **Algae** for conjugation in plants.) (A.W.L.)

CONJUNCTIVA. The thin membrane which covers the eyeball and is continued as a lining of the eyelids. (D.M.H.)

CONJUNCTIVITIS. Inflammation of the **conjunctivae.** This may be caused by wind, dust, or other foreign bodies, or infection. **Staphylococci, gonococci** and other bacteria may be the etiological agents. (D.M.H.)

CONNATE WATER. A term proposed by A. C. Lane in 1908 for underground water which is preserved as the water, fresh or saline, in which the **sediments** were originally deposited. (R.M.F.)

CONNECTING ROD. The common connecting rod is one of the four elements of the mechanism known as the slider crank chain. This mechanism consists of a base which carries two members, one of which rotates while the other reciprocates. The connecting rod connects the reciprocating and rotating elements by means of pinned or hinged joints at its ends, the same constituting the connecting rod bearings. The importance of this mechanism, and of its elements, including the connecting rod, is that it is the basis for a large number of machines of great importance to modern civilization. This is probably due to the fact that in so many cases a reciprocating motion is produced where rotary is desired, and vice versa. Among the more common illustrations of the machines of which the connecting rod is a vital and important part, are **engines, pumps, compressors, punches,** etc. A familiar example is the connecting rod of the gasoline engine. This engine derives its power from the push of the exploding gas against the reciprocating piston. One end of the connecting rod is joined to the piston by the wrist pin on which it has bearing. The other end of the connecting rod has a bearing on the rotating crank pin. Thus the connecting rod has a composite motion: one end of it reciprocates, while the other rotates. It is subject not only to tension and compressive stress, but also, by virtue of its inertia, to transverse bending. Due to this latter factor, high-speed connecting rods are carefully designed so that their mass will not only be as small as possible, but so placed as to cause the least shaking forces. Commonly used sections are the solid rectangular, the I-beam, and the tubular. Almost all materials, including cast iron, brass, wood, steel, aluminum alloy, have at one time or another been used for connecting rods. (F.T.M.)

CONNECTIVE TISSUE. The connective **tissues,** as the name suggests, are primarily those which bind together other structures. They are derived from the loosely arranged **mesenchyme** of the embryo and are characterized in the adult by the presence of various kinds of cells and of much intercellular substance, also in various forms.

In addition to **bone** and **cartilage** the connective tissues of the adult **vertebrate** include the loose irregularly arranged tissue which underlies the skin and occupies spaces between other organs. In this tissue lie cells which produce its own structures, blood cells, fat cells, and cells which become active in the repair of wounds. Between the cells is a soft matrix containing two kinds of fibers: white and elastic. The white fibers give tensile strength to the tissue and the elastic fibers give elasticity.

The other connective tissues are made up of certain of these structures. Thus **tendons** and **ligaments** are composed principally of parallel white fibers. Fibrous membranes may be either elastic or tough according to the fibers composing them.

Some of the connective tissues have other functions which are not associative. Adipose tissue, for example, is composed largely of cells in which fat is stored.

Some minute parts of many organs are held together by a network of reticular tissue whose fibers run in all directions among the cells of the organ.

The development of these tissues is so extensive that if all other components of the body could be removed, its gross form would still be evident. (A.W.L.)

CONODONTS. **Invertebrate Paleontology.**

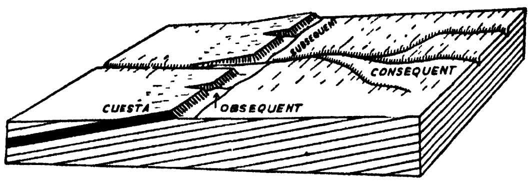
CONRADSON CARBON TEST. This test is an indication of the percentage of carbon residue in an oil, either fuel or lubricating. Where lubricating oil is exposed to high temperatures during use, a certain amount of carbon remains after the volatile parts of it have been volatilized. This is true of the lubrication of the cylinders of the internal combustion engine, one of the objectionable features of which is the deposit of carbon in the cylinder head after continued use. Likewise with fuel oils, especially the Diesel fuel oil, carbon residue is an important characteristic. Although not very well understood at present, even by many of those associated with Diesel power development, recent research indicates that the carbon residue as indicated by tests such as the Conradson, may be expected to be an important factor in the selection of a fuel oil.

The Conradson test consists of heating, under special conditions, a weighed sample of the oil at a sufficiently high temperature to volatilize all of the volatile matter of the oil. Once the distillation is completed, there remains the carbon residue, which is determined by weighing. Although it is objected that this test fails in many important respects to duplicate the conditions under which a carbon residue is formed in internal combustion engines, it is a reasonably successful indicator of the value of an oil with respect to its carbonizing qualities. (F.T.M.)

CONSANGUINITY. As used by geologists this term implied the "blood relationship" of **igneous** rocks. Proposed by Iddings in 1892 to designate a related group of igneous rocks which have been derived from a com-

mon **magma** and thus form a distinct **petrographic province.** (R.M.F.)

CONSEQUENT STREAMS. The type of **drainage** pattern which develops on the initial slopes of a land surface newly exposed to **erosion** by running water.



Block diagram to illustrate the meaning and relations of consequent and obsequent streams, in a youthful stage of the normal cycle of erosion, in a region of tilted strata. The more resistant rock layer (in black) stands out in the form of a cuesta, against the erosion.

Some such surfaces, as in coastal plains, are underlain by sedimentary strata gently tilted in the direction of surface slope. If one of the parallel series of tilted formations is more resistant to erosion than the others, a cliff or **cuesta** will be developed. Stream valleys which develop parallel to the cuesta are called subsequent, and their tributaries which cut back into the cuesta are called obsequent. (R.M.F.)

CONSERVATION OF ENERGY. Energy.

CONSISTENT STATISTIC. A **statistic** is said to be consistent if when calculated from the whole **population** it gives the correct value of the **population parameter.** More precisely as the size of the sample N **increases** then

$$\lim_{N \to \infty} P\{ | \theta_1 - \theta | > \epsilon \} \to 0,$$

that is, the probability that the statistic θ_1 differs from the population parameter θ by more than ϵ in absolute value approaches zero. The least one should demand of a statistic is that it be consistent. (L.A A.)

CONSTANT BOILING MIXTURE. Distillation.

CONSTANT CURRENT TRANSFORMER. This is a specially constructed **transformer**, sometimes called a tub transformer, built so the **primary** and **secondary** can move relative to one another under the influence of the forces set up by the load current. The currents in the primary and secondary react on one another to produce a repelling force between the two windings, the greater the current the greater the force. The secondary is movable along the core and is partially balanced by a counter-weight which is adjusted so the current forces will produce just the right reaction to hold the current essentially constant. An increase of current increases the force and hence the separation, which in turn increases the leakage flux between the windings ,and lowers secondary voltage. The lowered voltage causes a reduction of the current to a value which, when equilibrium is reached, is practically constant. Reduction of the load current causes an opposite sequence of reactions. These transformers are used in series street-lighting circuits to maintain constant current when the lamps short out because of trouble. (L.R.Q.)

CONSTANT OF INTEGRATION. Indefinite Integral.

CONSTANTS. A constant is a symbol for a single number.

An absolute constant is one which has always the same value. The symbol for such a constant may be a particular number-symbol, as 5 or ⅛ or $\sqrt{2}$, or it may be a special symbol always representing the same number, as $\pi \approx 3.1416$.

An arbitrary constant is one which has only one particular value in a given case, but may have another value in another case.

Arbitrary constants are often represented by letters, as a, b, c, etc., from the first part of the alphabet. (L.L.S.)

CONSTANTS, LINE. Line, Transmission.

CONSTELLATIONS. In astronomy this term is used to designate certain groupings of the **stars.** From earliest recorded history we find that the larger star groups (constellations), the smaller groups (asterisms such as the **Pleiades**), and the individual stars have received names symbolizing meteorological, religious, or mythological beliefs. The idea that the constellation names and myths are of Greek origin has been quite completely disproved. It seems highly probable that they are of Semetic or Pre-Semetic origin and that they found their way into Greece through contact with the Phoenicians (sailors who used the stars constantly in their profession).

The oldest record of actual constellation listing is found in the Creation Legend in about 650 B.C. This Legend was recorded on Cuneiform from even earlier records. From this time onwards frequent references to the constellation legends are to be found both in poetical and historical writings. The basis for the modern constellation division is to be found in the list of 48 constellations published by Ptolemy in about 150 A.D. This list of Ptolemy is based upon the writings of his predecessors, notably Hipparchus.

The boundaries of Ptolemy's constellations were very indefinite and many visible stars were left out entirely. Furthermore, his list only covered that portion of the

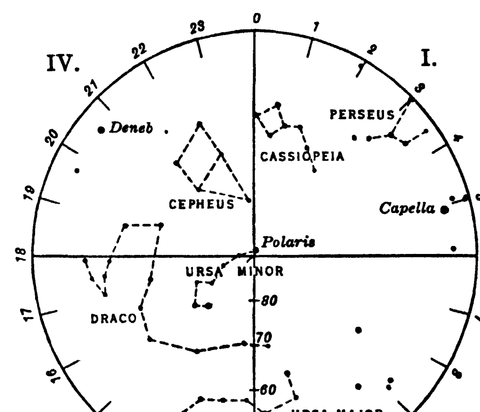


Fig. I. Circumpolar stars.

heavens visible from the southern Mediterranean regions. In the 1800 years since Ptolemy's time the list has been added to and the boundaries defined until at present all stars are included in some one of the constellations. The International Astronomical Union placed the matter of defining the constellation boundaries in the hands of a special committee and in 1930 the final list was published.

Several attempts have been made to supplant the ancient mythological names with more modern ones (e.g., the Coelum Stellatum Christianum of Julius Schiller in 1627 in which we find the ancient names replaced by names of various Church dignitaries) but none of the attempts have been successful.

The following list contains the names of all of the constellations now used; those in bold-face type are

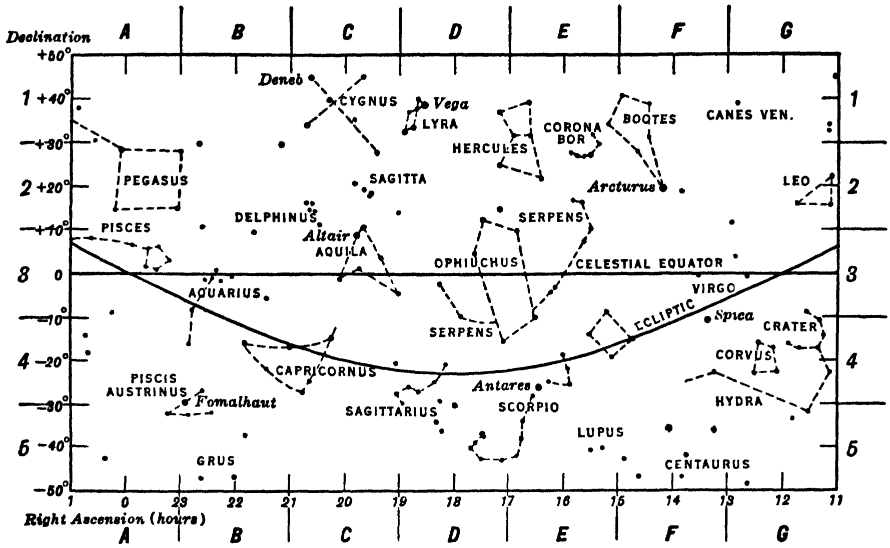

Fig. II Equatorial stars.

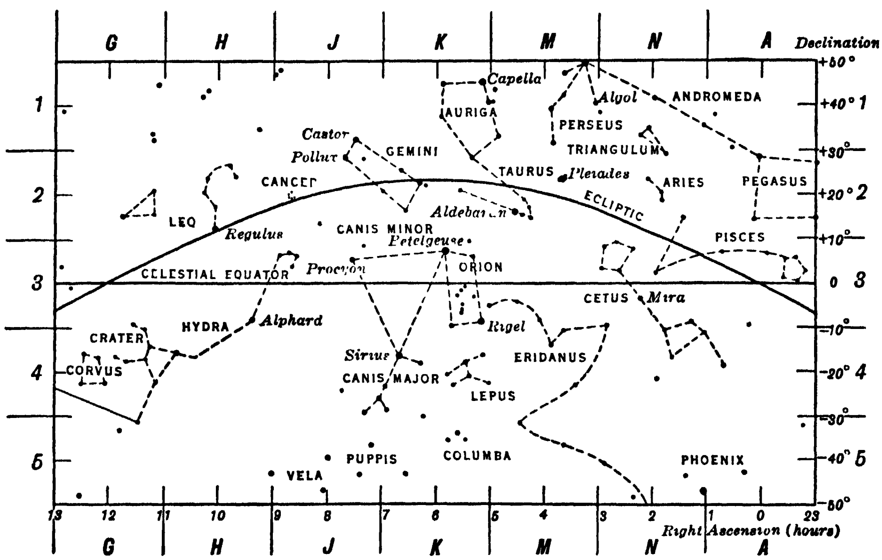

Fig. III. Equatorial stars.

treated elsewhere in this volume in special articles, and those marked with an asterisk are the original constellations of Ptolemy. The most important and easily recognized constellations will be found on the star maps, at the top of the page, and the numbers (e.g., Aries—Fig. III, 2, N) refer to the particular map and location on that map where the constellation will be found.

(W.K.G.)

CONSTIPATION. Infrequent or delayed passage of the intestinal contents. One of the most common causes in a normal person is neglect of the impulse to move the bowels. The stimulus gradually lessens or is lost entirely. Two factors are involved which prevent formation of a habit cycle of a daily bowel movement at a certain regular time. They are laziness and failure to adjust the time of impulse to the time of evacuation.

Constipation is common in those who take no exercise, and consequently suffer from an impairment of muscular tone. In other cases diet is at fault. It may be too concentrated, so that it leaves too little residue or bulk to enable the intestinal muscles to function properly. On the other hand, the diet may contain too much roughage, producing an irritated spastic colon. Certain individuals suffer from a spastic colon due to reflex nervous causes and normal intestinal function is prevented. Instead, the large intestine is usually in a state of spasm or contraction preventing normal passage of intestinal contents through it. Laxatives only increase the spasm; many functional symptoms accompany this condition with complaints of indigestion, abdominal pain and headache predominating.

The question of habit is an important one in the subject of constipation. Frequently the cause is a continued lack of bowel habit training beginning in infancy. Again, there are many individuals who believe, in some cases due to the pernicious influence of cathartic advertising, that they must "help Nature along." Gradually the artificial stimulus has to be increased and the dose must be increased or a stronger cathartic taken. Eventually the various drugs have little or no effect. The same applies to the enema habit.

In individuals with generally poor muscle tone there is insufficient tone to the intestinal muscles so that there is always a stasis with delay in passage of the intestinal contents, and constipation.

There are many local causes of constipation. These include weakness of the abdominal muscles, hemorrhoids or other painful disorders causing spasm of the sphincter muscles at the lower rectum, tumors either within the intestine or causing pressure from without, adhesions, bands or any structural defect or abnormality causing a partial obstruction of the intestines.

The symptoms of constipation depend largely on the cause of the condition. Many mistaken ideas about constipation have gained wide popular acceptance. Intestinal "auto-intoxication" is largely a myth. Symptoms from constipation occur chiefly in those whose nervous systems, especially the **autonomic** system, are easily disturbed—this is true particularly of those who suffer from spastic **colitis**. It must be remembered that certain individuals may normally have one, two, or three bowel movements a day, others may normally have a movement every other day. In other words, the frequency of bowel movements depends on habit. Certain individuals may have a daily bowel movement and still be constipated—producing a hard irritating movement instead of a normal semi-solid one.

Treatment of constipation involves correction of the cause and considerable habit training coupled with a satisfactory diet and avoidance of all laxative preparations and drugs. (R.S.M., D.M.H.)

CONSTRAINED MOTION. **Kinetics.**

CONSTRAINT. Constraint is that property which distinguishes a mechanism from other mechanical linkages. A mechanism has constrained motion in that a motion of one part is followed by a predetermined motion of the remainder of the mechanism. To determine whether a mechanical linkage is a mechanism or not, Klein advocates applying the criterion of constraint, which he writes as follows:

$$J = \frac{3N - 4 + \gamma - P}{2}$$

in which J is the number of joints in the mechanism, N is the number of links in the mechanism, γ is the number of independent prismatic chains, that is, those whose joints are of the sliding type, P = the number of point or line type of contact joints in the mechanism. When this equation yields an identity, the mechanism is said to be constrained for all dimensions. (F.T.M.)

CONSUMER'S RISK. Suppose a consumer accepts or rejects lots on the basis of **samples** chosen from such lots. The consumer's risk then is the **probability** of accepting lots on the basis of the sample inspection when such lots should in reality be rejected. The consumer's risk arises from the **error** of accepting lots which should be rejected. (L.A.A.)

CONSUMPTION. **Tuberculosis; Pulmonary Diseases.**

CONTACT FLYING. Conducting an airplane from place to place by constant reference to surface features on the earth is known as contact flying. The Civil Air Regulations of the Civil Aeronautics Administration are very specific in defining the amount of cloud, the range of visibility, and the height of **ceiling** with which contact flying may be attempted. Adherence to these rules will result in the view of enough surface features to permit the safe navigation of the plane without reference to instruments of navigation such as the **compass, radio,** etc., although Civil Air Regulations specify that certain of these instruments must be carried on the plane and in good condition. (W.K.G.)

CONTACT METAMORPHISM. **Metamorphism.**

CONTACT POTENTIAL DIFFERENCE. In his experiments with electroscopes, Volta found that when pieces of two different metals, otherwise insulated, are brought into contact, they acquire opposite charges and maintain a difference of electrical potential even while still touching. This potential difference he found to be characteristic of the given pair of metals. Thus when the metals are iron and copper, the iron has a potential about 0.15 volt higher than the copper, while for tin and iron the difference is 0.31 volt, tin being the higher. Volta listed a series of several metals, viz., zinc, lead, tin, iron, copper, silver, gold, such that when any two are put in contact, the one first named is at the higher potential. "Volta's law," which he was not in position to demonstrate but which was established much later, states that the potential difference between any two metals in direct contact is the sum of the potential differences between intervening metals of the series. Thus for tin and copper (above) it is 0.31 volt + 0.15 volt = 0.46 volt; and

it makes no difference whether the tin and copper are in direct contact or have other metals intervening between them.

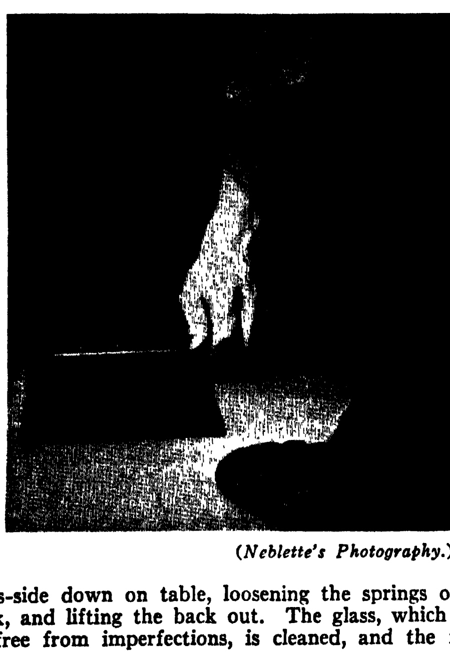
A distinction must be made between the contact potentials in air and the so-called "intrinsic" contact potentials in a vacuum with all adsorbed gases removed. According to Millikan, the intrinsic potential difference between two metals A and B is expressed by $V_{AB} = h(\nu_A - \nu_B)/e$, in which h in **Planck's constant,** ν_A and ν_B are the critical frequencies of photoelectric emission for the two metals (see **Photoelectric Phenomena**), and e is the electronic charge. In any case, if the electronic **work functions** of the metals are ϕ_A and ϕ_B, the contact potential difference is $V_{AB} = (\phi_A - \phi_B)/e$. The work functions, and hence V_{AB}, are in general dependent upon the medium surrounding the metals. Accurate measurements of these potentials are, unfortunately, very difficult. (L.D.W.)

CONTACT PRINTING, PHOTOGRAPHIC. In contact printing the photographic paper is exposed in contact with the negative. During exposure the exposing light passes through the back of the negative to the coated side of the paper; emulsion side of negative facing emulsion side of the print. Absolute contact at all points between negative and paper is necessary, if a sharp print is to be obtained. Contact printers should be checked frequently for uniform pressure over entire printing surface.

Prints with white margins are obtained by placing the negative on opaque, or non-actinic, masks, or the mask may be placed between negative and print. The latter position is usually adopted when printing glass plates.

Printing is controlled either by varying the length of the time of the exposure, keeping the intensity constant or varying the intensity of illumination and keeping the exposure time constant. The illumination is varied by increasing or decreasing the distance between light source and negative, or by using lamps of different power. The color temperature of the lamps has an effect on the time of exposure and on print contrast, but this is not critical with contact papers as these are sensitive primarily to the blue, violet and ultra-violet portions of the spectrum.

The simplest method of exposing prints is with a lamp and printing frame, as shown in the accompanying illustration. The printing frame is loaded by placing



(*Neblette's Photography.*)

glass-side down on table, loosening the springs on the back, and lifting the back out. The glass, which must be free from imperfections, is cleaned, and the frame dusted and a mask with the desired border is placed on glass first, then the negative with the emulsion-side up. To this is added, in proper safelight illumination, a sheet of sensitive paper, emulsion-side down. The back is replaced and springs are clamped down. While this method of printing is slow, it does offer excellent opportunities for shading of light areas and printing-in of dark portions of the negative.

The exposure on different parts of the negative, or "dodging," is accomplished by placing tissues and cutouts on glass plates under the printing surface or, on some machines, by raising the printing head and exposing local areas with a small spotlight held in the hand. (S.M.T.)

CONTAGION. The communication of disease by (1) immediate contact, (2) contact with excretions or secretions of a sick person, e.g., saliva by coughing, sneezing or talking, etc. (R.S.M.)

CONTINGENCY TABLE. A contingency table consists of r rows and s columns. It is similar to a correlation table but one of the **variables** (and usually both) is **qualitative** instead of **quantitative.** (L.A.A.)

CONTINUITY, PRINCIPLE OF. In brief, this is the principle that mass is indestructible and may be completely accounted for at different points of a steady flow even though physical changes have occurred. Also the mass of chemical elements which undergo chemical change during flow, becoming disassociated from or associated with other elements, may be identified at two states in a flow through application of the principle of continuity.

If an incompressible fluid flows steadily along a conduit past two stations where the cross-sectional areas of the fluid are found to be a_1 and a_2, respectively, then the mean fluid velocities v_1 and v_2 are related thus:

$$a_1v_1 = a_2v_2.$$

Had the fluid been compressible, then the continuity of mass would be exemplified by

$$a_1v_1d_1 = a_2v_2d_2$$

wherein d is the *density* of the fluid.

Again, suppose a fuel containing C lb. of carbon per lb. fuel is burned with air and the resulting products of combustion are analyzed for X lb. of CO_2 and Y lb. CO per lb. of gases. X and Y may be mathematically broken down and their carbon contents C_x and C_y established Then $C_x + C_y$ = weight of carbon per lb. gases. "Carbon continuity" implies that $C_x + C_y$ was continuously derived from C and so useful knowledge of quantity of gaseous products per lb. fuel burned may be obtained by expressing this continuity mathematically.

$$\frac{\text{Lbs. of gaseous products}}{\text{Lb. fuel}} = \frac{C}{C_x + C_y}.$$

This principle is susceptible of useful application to numerous other problems in the field of mechanical and chemical engineering. (F.T.M.)

CONTINUOUS BEAM. A continuous beam is one which has more than two supports. A beam which is continuous over several supports offers more difficulty in analysis than would a series of freely supported beams covering the same overall span. Because of the restraint at the intermediate supports, the continuous beam can carry a greater load than a simple beam of the same size and span. It is quite important to provide a firm **foundation** for the intermediate supports, as small **deflections** due to sinking of an intermediate support may introduce **stresses** of an entirely different nature and magnitude from those used in designing the beam. (F.T.M.)

CONTINUOUS FUNCTION. A function of one variable $f(x)$ is said to be continuous at a value $x = c$ when $f(c)$ has a definite finite value which is equal to the limit of $f(x)$ when $x \rightarrow c$:

$$\lim_{x \rightarrow c} f(x) = f(c).$$

This may also be expressed as follows: $f(x)$ is continuous at $x = c$ if $f(c)$ exists, and if for any arbitrary number $\epsilon > o$ there exists another number δ such that $|f(c) - f(x)| < \epsilon$ for all values of x such that $|x - c| < \delta$.

A function $f(x)$ is said to be continuous in an interval (a, b) when it is continuous at every point of the interval, it being sufficient at the end points that

$$\lim_{x \rightarrow a^+} f(x) = f(a),$$

and

$$\lim_{x \rightarrow b^-} f(x) = f(b).$$

A function is said to have a discontinuity at a point where it is not continuous. The usual type of discontinuity is a point at which the function becomes infinite, or where it has a finite jump.

Important properties of a continuous function are the following:

If $f(x)$ is continuous in a closed interval (a,b), then among the different values of $f(x)$ in (a, b), there is a greatest value M and a least value m.

If $f(x)$ is continuous in an interval (a, b), then between every two values x_1 and x_2 of x in (a, b), $f(x)$ takes at least once every value between $f(x_1)$ and $f(x_2)$.

A function of two variables, $f(x,y)$, is said to be continuous at a point (a, b) if

$$\lim_{\substack{x \rightarrow a \\ y \rightarrow b}} f(x, y) = f(a, b). \qquad \text{(L.L.S.)}$$

CONTINUOUS SPECTRUM. Light or other radiation may have such composition that, when analyzed with a **spectroscope** it presents apparently an unbroken continuity of wavelength over a wide range. Such, for example, is the light from an ordinary lamp filament. Any incandescent solid, liquid, or gas under high pressure will radiate with a continuous **spectrum.** In contrast to this, the spectrum of a glowing gas, as in a **neon** tube, is made up mainly of sharply defined maxima ("lines") or of more diffuse bands with dark spaces between them. Sunlight appears to have a continuous spectrum until analyzed carefully, when the continuous spectrum is found to be crossed by a multitude of dark **Fraunhofer lines.**

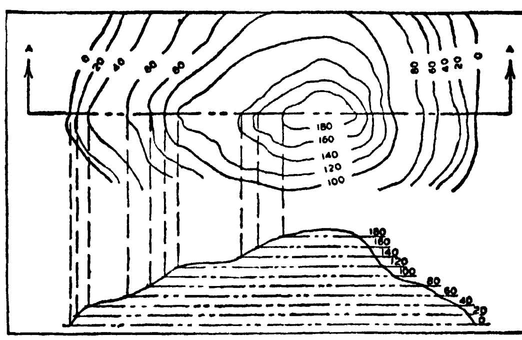
A continuous spectrum may extend without interruption from the extreme **infra-red** to the extreme **ultraviolet.** Study with a **spectrophotometer** will indicate that the relative intensity of the radiation differs in different wavelengths, having a well marked maximum at some particular wavelength. The position of this maximum intensity is a function of the temperature of the source, and the study of **spectral energy distribution** in stellar spectra provides a method for the determination of the temperatures of the stars. (L.D.W.)

CONTINUOUS VARIATE. A continuous variate is one which may have any value either integral, fractional, or irrational within the range of variation. Examples of continuous variates are the weights of objects, the ages of people, etc. A **variate** which is not continuous is said to be **discrete.** (L.A.A.)

CONTINUOUS WAVE. Continuous wave transmission in radio is the standard type now for radio telegraph communication. It means a wave which is constant in amplitude, as opposed to the varying amplitude of a modulated wave, and which changes only during **keying.** For transmission of the dots and dashes of the telegraph code the wave is transmitted at constant amplitude for a time corresponding to the length of the dot or dash. This type transmission when combined with modern receiving systems produces much better reception than the previously used **damped waves** or **interrupted continuous waves.** A much narrower **frequency channel** is required for this type than for the other types. Reception is by the heterodyne principle of beating another locally generated signal (see **Beat Frequency Oscillator**) to produce an audible note. (L.R.Q.)

CONTOUR. A contour is an outline or a boundary line, or it is a line passing through a series of points, all of which have some one characteristic in common. The contour is a useful means of displaying on one plane described by x and y coordinates, the interrelation of three variables, x, y, and z. Each contour line drawn upon the xy plane represents a single value of the variable z.

In surveying terms, a contour is a means by which the three dimensions necessary to represent a point in space can be shown on a map. These three variables are, length measured north and south, length measured east and west, and height, above some arbitrary reference plane. On a **topographical map** height is shown by contours. All points on a given contour line will be at the same elevation. The accompanying figure shows



Contours.

the relation between height of a small irregular hill, and the corresponding contour lines as drawn upon a map. Occasionally special maps, instead of showing elevation as the third variable, give line of constant magnetic **declination.** These lines are called isogonic lines and the map is known as an isogonic chart.

While the contour line has its greatest use in land surveying and mapping, there are other technical uses. For example, the efficiency of a centrifugal pump varies both with the pumping head and with the discharge. Accordingly, centrifugal pump characteristics are often given with the efficiency displayed as contour lines upon a head-discharge plane. (F.T.M.)

CONTRACTILITY. The fundamental property of living matter on which its power of movement depends. In the simplest forms of living things it is evident in a flowing movement of the material of the **cell.** In more complex forms the property is centralized in muscle tissue. Muscle cells are elongate and are so arranged that necessary movements result from their shortening when stimulated. Chemical explanations of contractility have been formulated but they are theoretical. (A.W.L.)

CONTROL. An experiment or test done to confirm or to rule out error in clinical or experimental observations. (R.S.M.)

CONTROL COLUMN. A lever having a rotatable wheel mounted at its upper end for operating the longi-

tudinal and lateral control surfaces of an airplane. This type of control is called "wheel control."

A control stick is the vertical lever by means of which the longitudinal and lateral control surfaces of an airplane are operated. The elevator is operated by a fore-and-aft movement of the stick; the ailerons, by a side-to-side movement. (F.T.M.)

CONTROL, MOTOR. Two major types of control of **motors** are needed in the usual industrial applications. For any but the smallest motors some type of control must be provided for starting the motor without throwing excessive load on the line or excessive current surges on the motor. For this type see **starter, motor.** The second type of control which is often needed is speed control. This may be accomplished in several ways, depending upon the type motor and the required degree of control. D-c motors are more easily controlled than a-c ones and consequently are frequently used where a high degree of control is required. Shunt- or compound-wound machines are normally used and in either case the speed may be increased by putting resistance in the shunt-field circuit. This gives an efficient means of speeding up the motor since the field current is small and hence the loss in the resistance is small. To slow down such a motor it is necessary to decrease the armature voltage. This may be done by inserting resistance in the armature circuit, but this is very inefficient since the armature current is high, causing the loss in the resistance to be high. A much more efficient and at the same time more versatile method is the use of **thyratrons** to control the motor armature current or the use of an auxiliary motor-generator set to control the voltage applied to the armature. (See **Phase Shift Control.**) Motors are also operated with armatures in series to reduce the speed. While this does not give continuous speed control by itself it does give an efficient low-speed operating condition.

A-c motors are more difficult to control. The usual induction motor is essentially a constant-speed motor and the synchronous motor must operate at constant speed. The a-c series motor is subject to very wide speed variation under load, just as its d-c counterpart, and may be controlled, inefficiently, by series resistance. The most common method of controlling the speed of an a-c motor is the rotor resistance control of a wound-rotor induction motor. The rotor windings are connected to the outside circuit through **slip rings** and **brushes** so extra resistance may be inserted. For fixed load the speed of the motor varies with the rotor resistance so this gives a method of adjusting the speed. It corresponds to the d-c control with armature resistance and is inefficient. Special types of motors have been developed and elaborate control systems devised but their use is not too common. **Concatenation** is another method of getting reduced speed operation where continuous control is not necessary. By a combination of concatenation and rotor resistance control better efficiency with complete control is obtained. (L.R.Q.)

CONTROLLABILITY. The quality of an aircraft that determines the ease of operating its controls and/or the effectiveness of displacement of the controls in producing change in its attitude in flight. (F.T.M.)

CONTROL SURFACE, AIRPLANE. The control surfaces of an airplane are movable airfoils arranged to be moved by the pilot to change the attitude of the airplane during flight.

The primary surfaces of a monoplane are (1) **ailerons,** one on each wing, (2) a **rudder,** and (3) an **elevator.** Operation of these impresses (1) rolling, (2) yawing, and (3) pitching motions on the airplane. Roll and yaw are not independent and a roll may induce a yaw without the rudder being operated; similarly, yaw with rudder may induce a roll.

The secondary surfaces are those designed to reduce the force necessary to operate the primary surfaces. These consist of trim and balance tabs.

Besides the above, flaps and air brakes might be considered as control surfaces.

The customary position of these control surfaces is:

1. Ailerons. Form a hinged rear section of the wing, occupying 10–20% of the chord and 20–50% of the span.
2. Rudder. Hinged to the rear edge of the vertical **fin.**
3. Elevator. Hinged to the rear edge of the **stabilizer.** (F.T.M.)

CONTROLS, AIRPLANE FLIGHT. Flight controls of an airplane are installed to give the pilot control over the three types of motion possible around its center of gravity, viz., **pitch, roll,** and **yaw.** The primary flight controls are those which operate elevator, aileron, and rudder. Secondary flight controls operate the trim tabs or stabilizer adjustment, and flaps.

The pilot gives his principal attention to the primary controls which are actuated by a control stick, or column, and pedals. Principles of both wheel and stick control are illustrated. It is observed that the wheel or stick

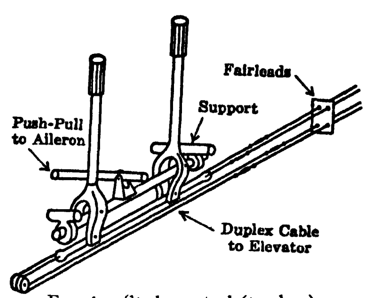


Fig. 1. Stick control (tandem).

controls only ailerons and elevator, for in any case the rudder is controlled by foot pedals. Wheel and column control may be applied to all sizes of airplanes, but stick control is restricted to the smaller airplanes There are four possible dual control arrangements as either wheel or stick control could be used with either

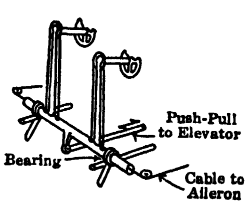

Fig. 2. Wheel control column (side by side).

tandem or side-by-side seating. Only two of these are illustrated. The control motions required are logically consistent with the resulting airplane motion. A backward pull on wheel or stick and the nose rises, a push forward and the nose drops into a glide or dive. Simi-

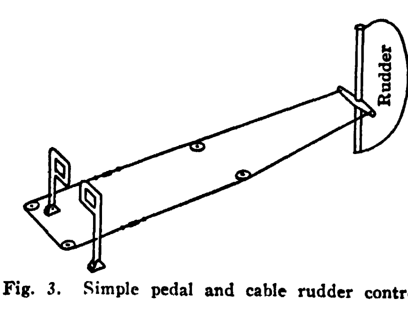

Fig. 3. Simple pedal and cable rudder control.

larly, a left movement of the stick, or counter-clockwise turn of the wheel, rolls the airplane counter-clockwise (as viewed by the pilot), while a push on the left rud-

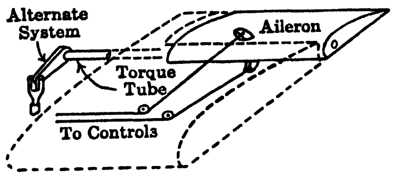

Fig. 4. Aileron control.

der pedal swings the airplane into a left yaw. The airplane may be pitched without engaging in roll or yaw, but if it is rolled it will also yaw and vice versa. Hence lateral stick or wheel motion must be correlated with pedal action for smooth banks and turns. Some attempts have been made to simplify the controls to two elements. Theoretically either aileron or rudder control might be omitted if the airplane were strongly stable laterally or directionally, since a banked turn may be accomplished by use of ailerons or rudder alone. Whether the sacrifice of maneuverability is worth the advantage of simplified control is debatable.

Three common methods of transmitting motion from controls to the surfaces they actuate are (1) flexible cables, (2) push-pull rods and tubes, (3) torque tubes. Where transmission distances are great as in transport planes, cables are favored because of low weight, freedom from vibration, and absence of lost motion. Pulleys, rollers, fairleads (guides of a non-abrasive material), bellcranks, and levers are required to support, guide, and change the direction of the tubes or cables. The details of their assembly vary with every make and model of airplane

Secondary controls are principally those operating trimming devices, the most common of these being a **tab** located in the trailing edge of the control surface. These are only infrequently operated in flight. They are often not essential but provide for pilot comfort by allowing the airplane to be trimmed for "hands-off" (of the primary controls) flight in a predetermined heading. Tabs are generally cable-operated from cranks, wheels, or dials, located convenient to the pilot.

The maneuvering forces developed by the control surfaces are many times the force required on the controls by the pilot. It is not uncommon to have 10 lbs. pull-back on the control stick produce 100–200 lbs. force on the tail surfaces. Only a small part of this multiplying action can be credited to the mechanical advantage of the control linkage. Furthermore, a relatively small portion of the incremental maneuvering force is developed on the control surface itself. One looks to the effect of the control surface displacement on the surface to which it is attached for an understanding of the magnitude of the forces involved. The rotation of a hinged surface, such as an elevator, about its hinge line changes the effective *camber* of the entire surface of the stabilizer. Similarly, an aileron movement changes the effective camber of the wing ahead of it. As camber of an airfoil is increased the lift on it increases. A small movement of the elevator may therefore produce large forces, which act principally on the fixed stabilizer surface.

The control forces exerted by the pilot are therefore only a small part of the total maneuvering force acting; however, they may be uncomfortably large if the airplane is a big one. Larger airplanes develop heavy forces on the control surfaces and only by trim adjustment could the pilot manually control the airplane without excessive fatigue. Such craft are usually equipped with an **automatic pilot** which will relieve the pilot of much of the effort required in piloting larger airplanes. (F.T.M.)

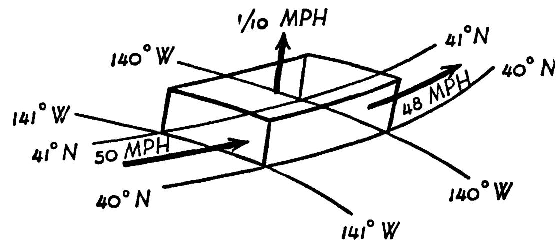
CONURE. Aves, Psittaciformes. Small **parrots** of numerous species found from Mexico into South America. Their prevailing colors are green and yellow. The Carolina paraquet of North America is a member of this group. (A.W.L.)

CONUS ARTERIOSUS. **Bulbus cordis.**

CONVECTION. **Thermal Convection.**

CONVECTION CURRENTS. Air currents that travel vertically. Convection can be either mechanical or thermal. Orographical and frontal lifting are mechanical convections of whole layers of air; whirlwinds, dust devils, air mass, cumulus clouds and thunderstorms are results of small-scale convection. (P.E.K.)

CONVERGENCE AND DIVERGENCE. If an imaginary box is erected in the atmosphere near the earth's surface in such a manner that its base, top, and



sides are parallel to the air flow, i.e., the winds, it is possible to illustrate the effects of convergence and divergence. When air flows uniformly through this box there will be no accumulation or diminution of air inside the box. If, for any reason, however, more air flows into one end of the box than flows out the other, there is an accumulation of air which must seek an outlet. Because the pressure is less at the top of the box than at the bottom, this accumulated air flows upward out of the box. If we followed a cube-shaped unit mass of air through this flow it would become distorted into a rectangular prism elongated vertically. This process is called convergence and results in a field of rising air. Converging, and therefore rising air can, if the process endures over a sufficient period of time, produce clouds and precipitation. It also tends to destabilize the air. If, in the same box, less air flows into one end than flows out the other, there is an air diminution and space is available at the top of the box for more air. One unit cube of air will be flattened into a rectangular prism elongated horizontally. This process is called divergence and results in a field of sinking or subsiding air. Divergence, therefore, and subsiding air tend to stabilize the air. Clouds and turbulence diminish in regions of divergence and subsidence. (P.E.K.)

CONVERSION EFFICIENCY. This term is applied to vacuum tube **amplifier** and **oscillator** circuits and denotes the a-c (usually radio frequency) output divided by the d-c input to the plate circuit. It is also called the plate efficiency. It varies quite widely with different classes of amplifiers, running as high as about 80% in some class C amplifiers, from 30 to 70% (depending upon conditions) in class B and being of the order of 20% in the usual class A amplifier. (L.R.Q.)

CONVERSION TRANSCONDUCTANCE. This is one of the vacuum-tube coefficients which is valuable in predicting the behavior of the **tube** in a circuit. It is applied to the mixer tube (first detector or converter) of a **superheterodyne** receiver and may be defined as the intermediate frequency current in the plate circuit divided by the applied radio-frequency voltage at the **control grid**. It is also used in connection with detectors

where it gives a measure of the audio-frequency output to be expected for a given modulated radio-frequency input. (L.R.Q.)

CONVERGENCY OF SERIES. **Infinite Series.**

CONVERTER. In certain fields of engineering the nature of the desired electrical power may be different from that available. For example, an electric railway having d-c **motors** propelling its rolling stock may obtain its electrical energy in the form of **alternating current.** This situation calls for the conversion of a.c. to d.c. with little loss. The converter accomplishes this. If a conversion is made from d.c. to a.c., we have an inverted converter. The most common type of rotating converter at present is the rotary converter, which is essentially an **alternator** and d-c **generator** combined in one machine having a single **armature** and a single-field circuit. This is not to be confused with a motor-generator set which, although it may be classed as a converter, is basically two machines having separate armatures, and shafts connected by a **coupling.** The rotary converter receives a.c. at one set of terminals, and delivers d.c. at another. The energy delivered is less than that received by the amount of the converter losses, consisting of friction, resistance heat, and core losses. The converter is frequently called a synchronous converter or rotary converter. The mercury-arc rectifier is rapidly replacing the mechanical converter. For the use of the term converter in metallurgy, see **Bessemer Process.** (F.T.M., L.R.Q.)

CONVEYOR. Strictly speaking, a conveyor is any device which is capable of moving material from one point to another. The material may be moved intermittently, that is to say, in a succession of separate loads on the conveyor system, or continuously. The term furthermore embraces the conveying both in horizontal or vertical directions, or a combination of the two. This general definition of a conveyor would include a vast number of cases which it is not proposed to treat here. Ordinarily, a conveyor is thought of as a mechanical conveyor constituting a definite installation fixed in position except for its belts, buckets, sprockets, and other moving parts. Equipment for vertical conveying would come more properly under the designation of **hoist.** In many instances materials are conveyed at an angle to the horizontal, in which case the conveyor system partakes of the nature of a hoist. A conveyor may be designed either for handling loose bulk material such as coal, sand, ore, etc., or for handling individual parts during or after production.

One of the simplest and most-used conveyors consists of a **belt,** usually horizontal (although it is possible to use a belt conveyor at small angles), continuous over two end **pulleys,** one of which drives it. The belt is supported at intermediate points on rollers. For transporting material in bulk, the rollers are arranged so that the belt forms a trough, but for handling packages, as on a factory conveying system, the belt would be flat. Another simple form of conveyor is the drag conveyor, which, in its primitive form, consists of a flat, heavy chain which is caused to move along the bottom of a trough, and which drags with it the material being conveyed. The friction losses are comparatively heavy in this type. The flight conveyor is an improvement, since vertical wood or steel plates are attached to the chain and nearly fill the trough from side to side. These effect a much more thorough movement of material, and a reduction of friction and wear. The flight conveyor may be used at fairly steep angles.

Mass-production methods depend largely upon the successful application of conveyor systems to the enterprise. The mass production of automobiles is one of the best examples. Economies effected by maintaining the workman at a station and moving the material past him on conveyors have made possible the production of higher quality vehicles at moderate prices. The trolley conveyor is frequently used where parts are being fabricated on an assembly line. It is an overhead steel monorail which has suspended on it a number of 2-wheel trolleys the carriages of which are connected by a chain which serves to motivate as well as space them. The parts being conveyed are suspended from the carriages by appropriate attachments of the required design.

Movement of raw materials and finished articles is often accomplished in factories on roller conveyors. The roller conveyor is a line of parallel rollers. The load travels along the conveyor from roller to roller under the influence of a gravity force component derived from a slight slope of the conveyor. Articles having flat surfaces, such as boxes, may be loaded directly on such a conveyor.

An apron conveyor consists of two chains upon which are mounted a number of flat metal plates or boards which are small enough to allow the chains to pass over sprockets at the ends of the conveyor, but which between sprockets form a continuous flat moving apron upon which are placed the articles to be conveyed.

Bucket conveyors consist of a number of V-buckets which are fastened between two moving chains. In the plain bucket conveyor the buckets are fixed to the chains. Therefore, on horizontal runs, they must be carried through troughs and act much like flight conveyors. If the buckets are pivoted so that they always maintain a level position, they will carry the material on horizontal runs rather than scrape it. A long spiral worm revolving in a closely fitting trough forms a type known as the screw conveyor. Bucket elevators may accomplish vertical turns, trolley and roller conveyors may accomplish horizontal turns, but the others are essentially straight run conveyors. On them, turns must be made by dumping from one conveyor on to another running in the new direction. Some use has been made of pneumatic conveyors, in which loose material may be drawn along with the stream of air, or in which articles may be sent in special containers which, fitting the walls of the conveyor conduit rather closely, are moved along somewhat as air pressure would move a piston in a cylinder. Modern conveyors are usually driven by electric motors operating through reduction gearing in order to operate the conveyor at an appropriate speed. If inclined, the conveyor will be equipped with a device to prevent it from starting backwards when stopped. Various automatic or semi-automatic conveyor discharging devices are employed. Power requirements are minimized by the use of anti-friction bearings on rollers, sprockets, or pulleys. Wear is minimized by the use of hardened wearing parts, or allowed for by the use of renewable wearing parts. (F.T.M.)

CONVULSION. A violent spasm or involuntary contraction (generally a series of them) of a group or of all the body muscles. Convulsions may be associated with high fever due to any cause in children, and with infectious diseases of the central nervous system such as **encephalitis** and **meningitis.** Convulsions are commonly and regularly seen in **epilepsy, eclampsia, tetanus, strychnine** poisoning, **uremia** and brain injuries. Convulsive seizures may also be seen in **hysteria.** (D.M.H.)

CONY, CONEY. Mammalia. 1. Rodentia. The pika, *Ochotona,* a small stoutly built animal found at high altitudes in the northern hemisphere. Numerous species. 2. Hyracoidea. The hyraces, small rodent-like animals, form an order of their own. They occur in Syria, Arabia, and Africa. Most of the toes are armed with broad nails and the superficial resemblance to rodents is due to the long cutting teeth and the compact tailless body. (A.W.L.)

COOLANT. **Lubrication.**

COOLIDGE TUBE. X-Rays.

COOLING, INTERNAL COMBUSTION ENGINE. The products of combustion in an engine are necessarily at a high temperature when formed. Upon attainment of thermal equilibrium in the combustion chamber the gas may have a temperature of from 1000° to 1400° F. If the cylinder walls are not maintained well below 500°, overheating and breakdown of the piston-cylinder **lubrication film** can ensue. A deliberate and purposeful cooling of the outside of the cylinder wall is imperative. Usually about a third of the heating value of the fuel consumed must be abstracted by a system of cooling which therefore becomes an essential and major element of any internal combustion engine.

The heat received by the cooling system is dissipated to the atmosphere in the case of land mobile units such as automobiles, railcars, etc.; to the water on which engine-propelled vessels float; and either to the atmosphere or to large natural bodies of water or flowing streams in the case of stationary engines. Cooling systems may be divided into (1) those using air directly, and (2) systems employing a liquid for the cooling of the cylinder and combustion chamber. Liquid cooling is accomplished by surrounding the cylinder with a cooling jacket containing the liquid. Water is ordinarily employed, but there are two exceptions. One is met where cooling systems of an idle engine are exposed to water-freezing temperatures. Liquids of lower freezing point, either pure or in solution with water, are then substituted for water. Alcohol and ethylene glycol are two such liquids. There is another reason for using the latter as a cooling system liquid. Its boiling temperature is about 380° F., therefore the jacket liquid may be heated to a possible 250° instead of the 180° common in circulating water systems. This materially reduces both the required flow of coolant and the size of the radiator.

Direct air cooling is obtained by circulating air over the exterior of the cylinder. Heat transfer from cylinder to air is so much slower than to water that it becomes necessary to extend the exposure of metal surface by casting or machining cooling fins on the exterior of the cylinder and combustion chamber. Air- and liquid-cooled cylinders are compared in Fig. 1.

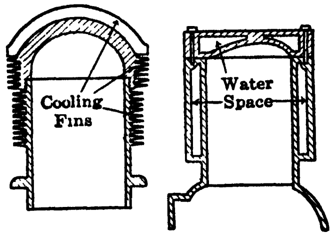


Fig. 1. Air and liquid cooled cylinders compared. (Valves and plugs omitted.)

Liquid-cooled systems may be further subdivided into evaporative and circulating types. Evaporative cooling is found on small stationary engines having hopper cooling. The water jacket is extended into an open hopper, or reservoir, so that a considerable quantity of water may be held. During operation of the engine the water is boiling. Heat is conducted away from the engine in the form of steam. Each pound of water evaporated will remove as much heat as 15 or 20 lbs. of water circulated but, unlike a circulating re-cooling system, water must be added periodically to the hopper to replace the evaporation. Most liquid-cooled engines employ the circulating system wherein the liquid is cooled externally and readmitted to the engine. A steady flow is maintained through the cooling jackets by means of pumps or **thermo siphon** action.

Methods of cooling the liquid are:

1. Pass the liquid through a "radiator" where, by conduction and convection (but very little radiation) heat may be removed by air blown through or across the radiator.
2. Pass the liquid through a surface heat exchanger and absorb the heat in raw water which may then be re-cooled or wasted.
3. Pass the liquid through a cooling tower or spray pond to cool it evaporatively.

A typical water cooling system for a gasoline tractor engine is shown in Fig. 2. Water is circulated from the

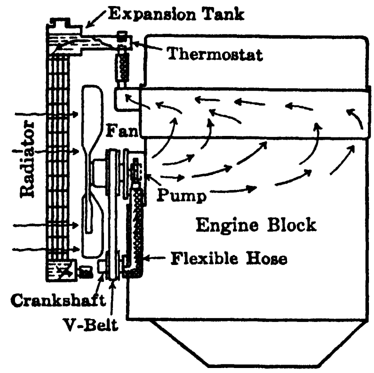

Fig. 2. Forced circulation water cooling system.

engine jackets to a radiator core where it is cooled, then withdrawn by an engine-driven centrifugal pump and sent through the cylinder jackets. From there it flows into the jackets surrounding the cylinder head and then back to the radiator. Since the radiator must be of sufficient size to obtain adequate cooling in hot weather, a thermostat is inserted in the flow line to maintain suitable engine temperature in cold weather.

Direct air-cooled engines are used in many power fields. Some have blowers to force the air to circulate over the cooling fins, while others depend on the motion of the engine itself to create the circulation. A motorcycle engine is illustrative of the self-cooled principle. The airplane engine is another. However, the latter is essentially a high-output engine installed under conditions demanding utmost efficiency of cooling. The air is carefully guided over its cooling fins by **cowling** so that the air used is the least possible and its usage is accomplished with a minimum of disturbance to the surrounding air stream. Effective air cooling of an airplane engine is so dependent on the cowling that it cannot be described except in conjunction with the cowling. Air-cooled engines habitually operate at higher temperatures than liquid-cooled, which gives them some thermodynamic advantage. It is common to consider the rear spark plug gasket temperature as the cylinder temperature and to embed a **thermocouple** in it for the activation of a remote reading thermometer. Typically the average temperature is 420° F., although 50° variation is possible among the cylinders of a multi-cylinder engine. The amount of heat to be removed by the cooling system is related to engine operation variables as follows:

1. Increase of engine power increases required cooling.
2. Increase of air fuel ratio decreases required cooling.
3. Increase of combustion air temperature increases required cooling.

There is an optimum ignition timing at which required cooling is minimum. Much research has been directed to the problem of fin size, spacing, heat transfer coefficients, etc., most of which was stimulated by the needs of the large air-cooled radial engine designer. The ratio of piston displacement to surface area of the cylinder increases with increase in cylinder bore, making it progressively more difficult to cool the engine adequately as larger sizes are attempted. In modern air-cooled aeronautical engines of high specific output, cooling is often the limiting factor in performance. (F.T.M.)

COOLING TOWER. The cooling tower is a means for cooling water through the medium of partial evaporation. The action that takes place is one whereby the stream to be cooled is broken up into a fine mist or rain, thus exposing a very large surface area. In this condition the water is mixed with air which is brought into the cooling tower by natural convection currents, or which is forced in by fans. If that air is not already saturated with water vapor, it will become so by coming in contact with the large area of moisture exposed in the cooling tower. The water is taken up by the air in the form of vapor at the partial pressure as determined by atmospheric temperature. It will, however, be vaporized to steam before it can become part of the humidified air. The heat necessary to effect this evaporation comes largely from the water itself. Since to vaporize a pound of water requires in the neighborhood of 1000 B.T.U., while to cool it 1° F. requires only 1 B.T.U., it follows that an evaporation loss of 5% of the water passing through a cooling tower is capable of reducing the temperature of the remaining 95% some 50° F.

Cooling towers are usually constructed of wood having wooden, sheet iron, or terra cotta interior baffles so arranged as to convert the stream of water delivered to the tower at its top into a large surface of exposure. The cooled water is retained in a catch basin at the bottom of the tower. Such cooling towers are frequently employed to cool the jacket water of internal combustion engines, and the circulating water of condensers of various types, i.e., in connection with refrigerating plants. Long, narrow cooling towers are more effective than squarely built ones. Higher cooling towers are more efficient than low ones. The efficiency of a cooling tower is stated as follows:

$$\text{Eff.} = \frac{\text{Hot water temperature} - \text{cold water temperature}}{\text{Hot water temperature} - \text{wet bulb temperature}}$$

A cooling tower in good condition should have an efficiency of at least 60%. (See **Absorption.**) (F.T.M.)

COOPERAGE. Wood.

COORDINATE PAPER. Rectangular Coordinates in a Plane, and Polar Coordinates in a Plane.

COORDINATES OF A POINT. Coordinates of a point are **numbers** which determine the position of the point.

In a plane, the position of a point is usually determined by either **rectangular coordinates** or **polar coordinates.**

In space, the position of a point is usually determined by either **rectangular coordinates, polar coordinates, spherical coordinates** or **cylindrical coordinates.** (L.L.S.)

COORDINATION. The regulation of an organism so that its various parts act cooperatively for the benefit of the whole.

Coordination depends upon the reaction of living structures to surrounding conditions, both inside and outside the body. Reaction to substances present in the body is classed as chemical coordination and reaction to stimuli which cause the transmission of impulses through the living substance is nervous coordination. The separation between the two is not sharp. In general the maintenance of a normal state in the body is due to the transformation and distribution of substances within it, or to chemical coordination. These processes are, however, subject to nervous regulation. The rapid transmission of nerve impulses likewise is conditioned by substances within the body. The two kinds of coordination are conspicuously illustrated by the action of **hormones** and of the **nervous system.** (A.W.L.)

COOT. Aves, Gruiformes. Birds (**Aves**) of several species occurring in Europe and Asia, North America, and Africa. They are waders and swimmers, with lobed toes. The plumage is dull in the adult, in contrast with the beak and part of the head. In the American species, *Fulica americana,* the beak is ivory-white. Although sometimes eaten, the coots do not rank with the ducks as food and game birds. (A.W.L.)

COOTER. Reptilia, Testudinata. A **turtle** of the genus *Pseudemys.* The several species are found chiefly in the eastern and southern United States. Also called sliders. (A.W.L.)

COPAL. Copal is the hardened **resin** derived from several tropical trees. One of these, *Trachylobium Hornemannianum,* is a large white-flowered tree of tropical east Africa. Another *Hymenaea Courbaril,* a tree with large white or purplish flowers, is a native of tropical South America.

The resin may be obtained from living trees, in which case it is a soft substance naturally slow to harden. In Zanzibar, copal resin occurs in fossil form, masses of resin closely resembling amber being dug from the ground. This is the best grade of copal, known as Zanzibar copal. Similarly in South America the resin may be dug from the ground at the base of the tree, where it slowly accumulates. Copal is used in the making of high-grade varnishes. Of late it is being supplanted with synthetic cellulose lacquers. Several other trees also yield copal resin. (R.M.W.)

COPALITE or **COPALINE.** The mineral copalite or "Highgate resin" is a fossil **resin** found in irregular fragments in the **blue clay** of London, England. It resembles copal, the resin of certain modern tropical trees. Copalite is pale yellow to greenish or brownish, and emits an aromatic odor when broken. It has a hardness of 1.5; a specific gravity of 1.046; burns with a very smoky yellow flame. (E.S.C.S.)

COPEPODA. A subclass of small **crustaceans.** Some species are free-swimming and others live as parasites on fishes. The latter are called fish-lice. (A.W.L.)

COPPER. Insecta, Lepidoptera. In zoology, coppers are small **butterflies** whose prevailing colors are coppery shades, often with metallic luster. With the **blues** and the **hairstreaks** they make up the family Lycaenidae.

Copper is the metallic element—Symbol: Cu (cuprum). Atomic number: 29. Atomic weight: 63.57. Density: 8.92. Hardness: 2.5–3.0. Melting point: 1083° C. Boiling point: 2310° C. (**Isotopes:** page 290.)

Copper is a yellowish-red metal, very malleable and ductile, soft, good **conductor** of electricity, but traces of certain impurities markedly decrease the **conductivity;** unattacked by dry air, but in moist air containing **carbon dioxide** a protective greenish film of basic carbonate is formed; dissolved best by **nitric acid,** not attacked by cold dilute **hydrochloric** or **sulfuric acid,** but in hot hydrochloric acid dissolves to yield cuprous chloride, in hot concentrated sulfuric acid to yield copper sulfate; attacked by **chlorine,** especially when heated, to form cuprous and cupric chlorides; only slight action by **hydrogen sulfide** or **sulfur dioxide** at ordinary temperatures in the absence of air. Very thin sheet copper is translucent and transmits greenish-blue light. Discovery prehistoric. Probably the first metal to be used by mankind. Copper is the second most largely used metal, being exceeded only by iron, and considerable scrap metal is recovered.

Copper is largely used (1) in construction and apparatus where workability is demanded of and definite resistances to corrosion supplied by the metal, (2) as an electrical conductor (99.95% Cu) commonly in the

form of wire, (3) as a constituent of various **alloys**, especially brass and bronze, coins, **aluminum** alloys, **nickel** alloys, and **steel**, (4) as a catalyzer when finely divided, for certain chemical reactions.

Copper occurs as native copper particularly in the region south of Lake Superior (often 99.9% Cu), as sulfides (**chalcocite**, copper glance, cuprous sulfide, Cu_2S; **chalcopyrite**, $CuFeS$), as oxide (**cuprite**, cuprous oxide, Cu_2O, red); as basic carbonates (**malachite**, $CuCO_3 \cdot Cu(OH)_2$, green; **azurite**, $2CuCO_3 \cdot Cu(OH)_2$, blue). The copper content of its ores varies from 0.3% to 8% Cu and the average is of the order of 2.5%. The value depends largely upon the content of silver and gold. The area of production is widely distributed, in the United States, Montana, Utah, New Mexico, Arizona, Michigan, Tennessee, in Canada, Mexico, Chile, Peru, Africa, Spain, Portugal, Japan. (1) Native copper ore is crushed, concentrated by washing with water, smelted, and cast into bars. (2) Oxide and carbonate ores are treated with **carbon** in a smelter. (3) Sulfide ore treatment is complex, but in brief, consists of smelting to a matte of cuprous sulfide, ferrous sulfide, and silica, which molten matte is treated in a converter by the addition of lime and air is forced under pressure through the mass. The products are blister copper, ferrous calcium silicate slag, and sulfur dioxide gas. Refining is conducted by electrolysis, and the anode mud is treated to obtain the gold and silver.

Acetates: Copper acetate, cupric acetate ($Cu(C_2H_3O_2)_2 \cdot H_2O$), greenish-blue solid, soluble, formed by reaction of cupric oxide (or copper plus oxygen of the air) and **acetic acid**, and then crystallizing. Used as an insecticide, fungicide; basic copper acetate, copper subacetate, "verdigris," green and blue solids, insoluble, color depending upon the ratio of copper oxide to copper acetate present, used (1) as paint pigment, (2) as insecticide and fungicide, (3) in dyeing and printing fabrics. (See **Arsenic**—Arsenites, and Arsenite below.)

Acetylide: Cuprous acetylide ($Cu_2C_2 \cdot H_2O$), red precipitate (explosive when dry), formed by passing **acetylene** into cuprous chloride solution in ammonium hydroxide.

Arsenite: Copper arsenite, cupric arsenite, "Scheele's green" ($CuHAsO_3$), light green solid, insoluble, poisonous, formed by reaction of soluble copper salt solution and **sodium** arsenite solution, used as paint pigment and insecticide; copper acetoarsenite, cupric acetoarsenite, "Paris green" ($Cu(AsO_2)_2 \cdot Cu(C_2H_3O_2)_2$), green powder, insoluble, used as (1) paint pigment, (2) insecticide, (3) in wood preservatives.

Bromide: Cuprous bromide ($CuBr$), white solid, insoluble, formed by reaction of cupric bromide solution and copper metal, or of excess copper metal with **bromine**; copper bromide, cupric bromide ($CuBr_2$), brownish-black solid, soluble, formed by reaction of cupric oxide and **hydrobromic acid**, and then crystallizing. Color of solution depends markedly upon the concentration, e.g., concentrated is dark brown, dilute is blue, intermediate is green.

Carbonates: Basic copper carbonates, green precipitate by reaction of soluble copper salt solution and sodium carbonate solution, or superficially by oxidation of copper metal in moist air containing **carbon dioxide**. **Malachite** (green) and **azurite** (blue) occur in nature.

Chlorides: Cuprous chloride ($CuCl$), white solid, insoluble, formed by reaction of cupric chloride solution and copper metal, or of excess copper metal with **chlorine**; copper chloride, cupric chloride ($CuCl_2 \cdot 2H_2O$) green crystals, soluble, formed by reaction of cupric oxide (or copper plus oxygen of the air) and **hydrochloric acid** and then crystallizing. Crystals become anhydrous and brownish-yellow at 110° C., the chloride melts at 500° C., and changes to cuprous chloride and chlorine gas at higher temperature.

Cyanides: Cuprous cyanide ($CuCN$), white solid, insoluble, formed by decomposition of cupric cyanide, upon heating with water, very poisonous **cyanogen** gas being evolved at the same time. Used in certain organic reactions, i.e., **Sandmeyer's** for benzenoid cyanides; cupric cyanide ($Cu(CN)_2$), brownish-yellow precipitate by reaction of soluble cupric salt solution and **sodium** cyanide solution. Upon heating with water, very poisonous cyanogen gas is evolved, and cuprous cyanide.

Ferrocyanide: Cupric ferrocyanide ($Cu_2Fe(CN)_6$), reddish-brown precipitate, formed by reaction of soluble cupric salt solution and **potassium** ferrocyanide solution. This is a very delicate test for copper, and enables the detection of as little as one part of copper in a million parts of solution.

Hydroxides: Cuprous hydroxide ($CuOH$, formula doubtful), yellow precipitate, by reaction of cuprous salt solution and **sodium** hydroxide solution, soluble to colorless solution by hydrochloric acid or ammonium hydroxide; cupric hydroxide ($Cu(OH)_2$), blue gelatinous precipitate, by reaction of cupric salt solution and sodium hydroxide solution, soluble to deep blue solution by ammonium hydroxide, cupric hydroxide is changed to black cupric oxide upon boiling with water, or upon standing.

Iodide: Cuprous iodide (CuI), white solid, insoluble, formed by reaction of soluble cupric salt solution and **potassium** iodide solution with separation of **iodine** at the same time. Used in certain organic reactions, i.e., Sandmeyer's for benzenoid chlorides.

Nitrate: Copper nitrate, cupric nitrate ($Cu(NO_3)_2 \cdot 6H_2O$), blue crystals, soluble, formed by reaction of cupric oxide (or copper) and **nitric acid**, and then crystallizing. Copper nitrate is decomposed, upon being heated, leaving cupric oxide residue and evolving nitrogen tetroxide and oxygen gases.

Oxides: Cuprous oxide, red copper oxide, (Cu_2O), red solid, insoluble, formed (1) by reaction of cupric salt solution in alkaline medium with a reducing solution such as glucose or arsenite. The cupric salt solution in sodium hydroxide is maintained by the addition of sodium tartrate or citrate. Fehling's test is the application of this reaction; (2) by superficial oxidation of copper upon heating to moderate temperature; cupric oxide (CuO), black solid, insoluble, formed (1) by the oxidation of copper upon heating in air, (2) by heating cupric hydroxide, carbonate or nitrate to red heat.

Sulfate: Copper sulfate, cupric sulfate, "blue vitriol," "blue-stone" ($CuSO_4 \cdot 5H_2O$), blue crystals, soluble, formed by reaction of cupric oxide (or copper plus oxygen of the air) and **sulfuric acid**, and then crystallizing. Crystals lose water upon being heated and the white residue of anhydrous copper sulfate is used to detect the presence or absence of water in certain organic liquids (water causes blue coloration).

Sulfide: Cuprous sulfide (Cu_2S), black solid, insoluble, formed by reaction of cuprous salts, e.g., cuprous chloride, with **hydrogen sulfide** or **sulfur** upon boiling; cupric sulfide, copper sulfide (CuS), black precipitate, formed by reaction of cupric salt solution and **hydrogen** or **sodium** or **ammonium** sulfide, soluble in dilute nitric acid.

Cupric salts (the common copper salts) dissolve in water to give a beautiful blue color; the crystalline salts are blue solids (e.g., sulfate, nitrate), green solid (e.g., chloride), brownish-black solid (e.g., bromide) and the oxide is black. The salt solutions yield, with excess ammonium hydroxide, a dark blue solution. Various forms of this solution are applied in special reagents, e.g., Fehling's, where reducing agents form cuprous oxide, and Schweitzer's, where cellulose is dissolved, and upon making the solution acid, cellulose is precipitated, as in the earliest artificial fiber process.

Cuprous salts are insoluble in water; the salts are white (e.g., chloride, bromide, iodide) and soluble in concentrated hydrochloric acid to brownish solution,

and in ammonium hydroxide to colorless solution (the blue coloration usually encountered is due to the presence of cupric). These solutions readily absorb **oxygen** or **carbon monoxide,** and are so utilized in the analysis of gases. Cuprous oxide or hydroxide is formed of various colors ranging from yellow to red. (R.K.S.)

COPRA. Coconut.

COPROLITES. Paleontology.

COPULATION. The act of sexual union by which the seminal fluid, containing the reproductive cells of

COPPER LOSS. This term is frequently used to denote the resistance loss in the conductors of electrical circuits or machines. In most machines there are two types of electrical losses, those caused by winding resistance, i.e., the copper loss, and those caused by the magnetic core, i.e., core loss. Copper loss is given by

$$P = I^2R$$

where I is the current and R the resistance. (L.R.Q.)

COPPER OXIDE RECTIFIER. Rectifier.

COPPERHEAD. Reptilia, Sauria. A poisonous **snake,** *Agkistrodon mokasen,* of the eastern United States, extending locally into the central states. It is a pit viper, related to the rattlers and water moccasin. The species frequents rocky uplands more than wet ground and is nocturnal and retiring in habits.

The reddish head of this snake has led to confusion with certain harmless species, including the hog-nosed snake. The copperhead can be distinguished with certainty by the pit between the eye and the nostril. It is not a large snake, usually reaching a length of less than four feet, and is not as dangerous as supposed because of its shy nature. Its bite is treated like those of the other **pit vipers.** (A.W.L.)

COPPERSMITH. Aves, Piciformes. A small Indian bird, *Xantholaema haematocephala,* one of the **barbets.** It is green above and yellow with green markings below. (A.W.L.)

the male, is transferred to the genital passages of the female.

The germ cells are adapted for locomotion through liquids, hence many aquatic species need only discharge them into the surrounding water simultaneously to enable them to come together for **fertilization.** If the egg is to develop in the body of the mother, however, or if the animal is entirely terrestrial, the liquid medium in which fertilization occurs is secreted by the body and a direct transfer from male to female is usually necessary. Artificial insemination of animals has been accomplished.

In some animals copulation is accomplished merely by the apposition of the orifices of the genital ducts, but in most cases the terminal portion of the female organs becomes a vagina for the reception of a male intromittent organ. This organ varies greatly. In some of the **rotifers** the pointed end of the body serves for the introduction of the germinal material, although some have a special projecting organ called the penis. Some of the roundworms have a pair of couplatory **setae,** which project from the alimentary tract. In the **crustaceans** certain paired appendages are modified for introduction into the female and in the **spiders** the male discharges the seminal fluid onto a web and takes it up into his **palpi,** which are modified for the transmission of the material to the female ducts.

Among the vertebrates most intromittent organs are in the form of a penis developed either as a projecting fold in the wall of the **cloaca** or as a protrusible organ associated with the urogenital passages at their caudal

extremity. In the **shark** the pelvic fins sometimes bear lobes which are thrust into the cloaca of the female during copulation. Copulation is associated with the involved process of **mating.** (A.W.L.)

COQUETTE. Aves, Micropodiformes. A **humming-bird** of a small group of species found from southern Mexico to southern Brazil. They are distinguished by the crested head and conspicuous frills at the sides of the neck. (A.W.L.)

COQUINA. This is a Spanish word meaning little shells. It is a coarse and highly porous **limestone** made up of shells and shell fragments loosely cemented. It is being formed at present along the coasts of Florida, where it is frequently referred to as "beach rock." Only a few of the limestone formations of former geological periods are true coquina. In Bermuda coquina, largely of **Aeolian** origin, is sawed into blocks and used as a building material. (R.M.F.)

CORACIIFORMES. An order of birds including the **hornbills, kingfishers and rollers.** (A.W.L.)

CORAL. Coelenterata, Actinozoa. The hard deposit built up by minute colonial animals called coral polyps which occur in the warmer oceans. The deposit consists principally of **calcium** carbonate.

The term coral is applied to the deposits of animals of two orders, **Alcyonaria** and **Zoantharia,** of different form and habits. Those of the alcyonarians are made up of minute spicules formed within the tissues, occasionally compacted in a hard central rod running through the entire colony and sometimes supplemented by an external covering. Red or precious coral is the

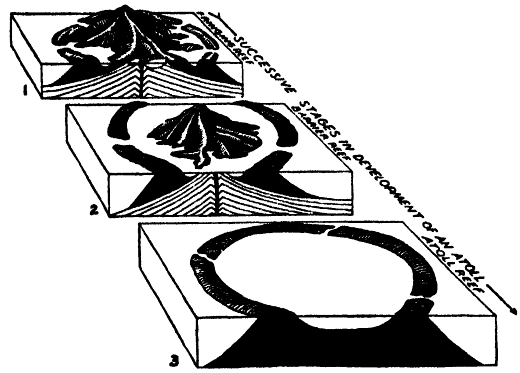
Coral. (*American Museum of Natural History.*)

hard axis of such a form and organ-pipe coral is made up of the connected tubes which once surrounded the living animals. Zoantharian corals build up hard deposits externally beneath the basal disk which attaches them to the ocean floor. As new individuals arise from the edge of the living tissue their deposits become continuous with those already laid down and so large colonies produce extensive masses of coral rock. The form of these deposits varies. Some are slender and branching and others rounded and massive. They have received common names such as staghorn coral and brain coral.

Precious coral is secured principally in the Mediterranean and is the foundation of a considerable industry in Italy. Several thousands of persons in that country work coral into beads and other ornaments and make it into jewelry.

The formation of coral islands in the warmer oceans has resulted in many habitable land masses, and in the same waters submerged reefs of this material are serious obstacles to navigation. (A.W.L.)

CORAL REEF. A complex, **ecological** association of benthonic (bottom-living) and attached, calcareous, shelly marine **invertebrates,** forming either fringing



Block diagrams illustrating the successive stages in the development of an atoll during the subsidence of a volcanic cone. (*Field, Laboratory Manual, Princeton University Press.*)

reefs, barrier reefs, or atolls. The lagoons of barrier reefs and atolls are important loci for the deposition of fine-grained calcium carbonate mud called drewite. Fossil reefs include all types of organic reefs which show a distinct ecological and structural evolution from the earliest known fossiliferous limestones to the typical atolls of the South Pacific Oceanic Islands. (R.M.F.)

CORBINO EFFECT. **Hall Effect.**

CORDAITALES. **Paleobotany.**

CORDIERITE (IOLITE) (DICHLORITE). The mineral cordierite, composition $Mg_2Al_4Si_5O_{18}$, is an **orthorhombic** mineral frequently seen, however, in pseudo-**hexagonal** forms, as well as massive. It is brittle, with a subconchoidal fracture; hardness, 7–7.5; specific gravity, 2.60–2.66; luster, vitreous; color, blue of varying shades; translucent to transparent. Cordierite exhibits pleochroism (or dichroism) being dark blue, light blue and light yellow when examined by transmitted light in different directions. Hence it is frequently called dichroite. It is occasionally used as a gem. Cordierite is found as a primary mineral in the igneous rocks. It is, however, found ordinarily in **gneisses, schists** and in areas of contact metamorphism. Localities for good specimens are numerous in Europe, including Bavaria, Finland, Norway. It is found in Greenland, Madagascar and Ceylon from which latter place come the rolled pebbles of a rich blue color known as saphir d'eau and prized as a gem. In the United States it is found principally in Connecticut. Named for the French geologist, Pierre Louis Antoine Cordier, this mineral has also been called iolite from the Greek word meaning violet, and stone, as well as dichroite from the Greek meaning *two-colored.* (E.S.C.S.)

CORE. A magnetic core is an important element in many applications in electrical design. Electromagnetic equipment, as exemplified by the **transformer,** the **motor,** and the **generator,** have electrical circuits, usually of copper conductors, and **magnetic circuits.** The magnetic circuit follows a path largely contained in a core composed of iron or iron alloys. The purpose of the core metal is to offer the best path for the magnetic lines of flux, and its success in this respect is measured by its permeability. Cores are usually composed of a large number of thin metal laminations which are fabricated by punching from thin sheets of metal, and after being enameled are assembled to form a core. The enamel forms an insulation between laminations which reduces the eddy currents induced in the metal of the

core by transformer action. Normal oxidation scale is frequently sufficient insulation for this.

A drilled core of suitable size is frequently removed from a material to be used as a sample for inspection or test. Thus, subterranean exploration with a diamond core drill brings up a core which gives a vertical section through the ground being investigated. If enough of these drillings are made in various positions, a fairly accurate picture may be formed as to the nature of underlying strata. However, not all core drillings are subterranean. It is a common practice for engineers to take cores from a newly constructed concrete road in order to determine the character of the contractor's work. The core will show thickness of the road slab, character of the concrete, and may be used to test for strength. (F.T.M., L.R.Q.)

CORE LOSS. All electrical machines have magnetic cores to provide easy paths for the flux which is necessary for the proper operation of the machines. The insertion of this core is not without its drawbacks, however, as it introduces additional losses known as core losses. In spite of the additional loss present in the magnetic material the over-all effect of the core is a tremendous increase in the efficiency of the machine because of the smaller currents needed to produce the desired magnetic flux. The core losses are composed of eddy current loss and hysteresis loss. The former is caused by the currents which are induced in the core material by the changing flux through it. This is, of course, much more pronounced in a-c than in d-c machines because of the much greater rate of change of the flux in the former. In order to reduce this loss the core of all a-c machinery and much d-c machinery is laminated or composed of thin sheets. The hysteresis loss is due to a sort of molecular friction when the molecules of the core try to align themselves with the magnetic field. While the two types of losses do not follow the same laws the total loss varies approximately as the square of the frequency if other factors are held constant, or about as the 1.5 power of the flux density if it is the only variable. (L.R.Q.)

CORIANDER. Carrot Family.

CORIOLIS EFFECTS (Acceleration or Force). Any object moving above the earth with constant space **velocity** is deflected relative to the surface of the rotating earth. This deflection was first discussed by the French scientist Coriolis about the middle of the last century, and is now usually described in terms of the Coriolis **acceleration** or the Coriolis force. The deflection is found to be to the right in the northern hemisphere and to the left in the southern.

As a first approximation to the problem we assume that an observer is at the center (C) (Fig. 1) of a disk

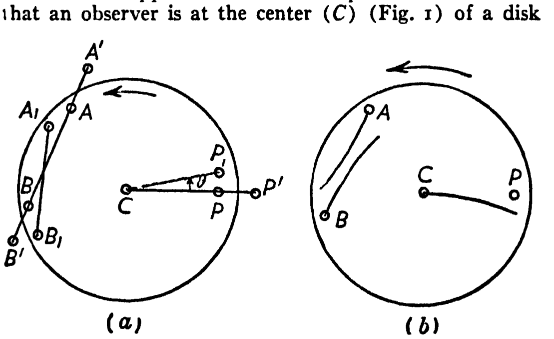


Fig. 1. Coriolis effects.

that is rotating with constant angular velocity ω. In Fig. 1(a) the observer can see objects off the disk and is conscious of the rotation. At a given instant, when the object P on the disk is directly in line with the point P' off the disk, the observer fires a shot at P. During the time (t) that is required for the shot to move over the distance CP at speed v ($CP = vt$), the disk will turn through the angle θ ($\theta = \omega t$). The observer notices that the bullet misses the point P, but that it hits P'. In Fig. 1(b) the observer's "world" is limited to the rotating disk and he has no way of knowing that his world is in rotation. Under these conditions when he fires a shot at P he will notice, as before, that the bullet misses P, and he will also determine that the shot follows a curve, similar to that shown, in his world. The same effects will be observed no matter where the observer is located in his world or in what direction he aims his shot (e.g., from A in direction BB', or from B toward AA'). The deflection is always to the right with the direction of rotation indicated in the figure, and would be to the left if the direction of rotation were reversed.

In accordance with fundamental definitions a curved motion represents an acceleration (a) and an acceleration is the result of the action of a force (f) which is proportional to the **mass** (m) of the object and the speed (v) with which it is moving. Analysis of the motions shown in the figure show that the acceleration relative to the disk is given by $a = 2v\omega$, or, since $\omega = \frac{2\pi}{T}$, in which T is the period of rotation, $a = \frac{4\pi}{T}v$. The force producing this acceleration will be given by $f = k\frac{4\pi}{T}mv$, in which k is a factor of proportionality whose value is determined by the units employed.

The conditions on the rotating earth in the vicinity of either pole of rotation are comparable to the "world conditions" on the rotating disk. The sense of rotation will be opposite at the two poles and the deflection will be to the right at the north pole and to the left at the south. The angular velocity of rotation of an area at any place on the earth in **latitude** L is given by $\omega = \frac{2\pi}{T}\sin L$, in which T is the **sidereal** period of rotation of the earth or 86,163.4 **seconds**. Hence the Coriolis acceleration is $a_c = \frac{4\pi}{T}v\sin L$, and the Coriolis force $F_c = k\frac{4\pi}{T}mv\sin L$.

The Coriolis effects must be considered in a great variety of phenomena in which motion over the surface of the earth is involved. Among these may be listed: 1. Rivers in the northern hemisphere should scour their right banks more severely than the left, and the effect should be more evident for rivers in high latitudes. Studies of the banks of the Mississippi and Yukon rivers indicate the predicted results. 2. The motions of air over the earth are governed, to an appreciable extent, by the Coriolis force. (See **Wind Equations.**) 3. A term, due to the Coriolis force, must be included in the equations for exterior **ballistics.** While the effect is negligible in small-arms fire, nevertheless, it is very important in the fire-control material for long-range guns. 4. Any **level** bubble, which is being carried on a ship or plane, will be deflected from its normal position. The deflection will be perpendicular to the direction of motion of the ship or plane. The correction for this effect may amount to several **miles** in the determination of a position of the ship or plane by methods of **celestial navigation** if the bubble octant is used in the necessary observations. (See **Sextant.**) (W.K.G.)

CORK. Cork cells are found in the outer **bark** of most woody-stemmed plants, but in amounts too small and with too brittle walls to be of any use to man. But in *Quercus Suber,* the Cork Oak, the cork cells become a very large part of the tissue of the bark, and have been used for centuries by man. The cork oak tree

is a medium-sized tree, seldom much over 50′ in height, growing in nearly all countries bordering the Mediterranean Sea. The evergreen leaves are small, 1½–3″ long, and about an inch wide, with slightly toothed margins. The bark of the tree soon becomes rough and deeply furrowed, but is of little value except as ground cork or as a source of **tannin.** When the tree is about 20 years old this first formed bark is removed, care being taken not to injure the phloem and **cambium** layers. Within 10 years a new cork layer has formed. This layer is the first of many layers which are removed once every 10 years or so throughout the life of the tree. Removal is generally done in the early summer at a time when hot dry winds will not cause injury to the unprotected phloem and cambium.

After removal, the cork is air-dried for a time, then boiled to soften it and to remove some of the tannin. The outer part of the bark is scraped off, and the rest pressed out flat and dried. It is then ready to ship.

The physical properties of cork account for its many uses. It is very light and buoyant, more than 50% of its volume being air, and hence is used in the manufacture of floats, life-preservers, and so forth. Since the living **protoplasm** of the cork cells dries up early in their development, leaving hollow cells, each containing a small mass of air which expands after compression, cork is very resilient, and is frequently used as a core on which to wind yarn or string in the manufacture of baseballs. In the early stages of their formation, the walls of cork cells are **cellulose,** but this is soon impregnated by a waterproof and non-absorbent lipoid substance, **suberin.** Therefore cork is used in making handles for fishing rods, shoe-soles, and cork stoppers. Since the hollow cork cells are poor conductors both of heat and sound, cork is much used as insulating material. For this use cork is ground up and then pressed into sheets with various binding materials, giving much larger sheets than can be obtained from the tree. Ground cork is also an important constituent of linoleum.

Cork is traversed by lenticels, loose masses of porous tissue, which appear as dark spots or holes in stoppers. Usually in making stoppers the bark is cut so that these will be transverse in the stopper. In making stoppers, the forms are first punched out as cylinders, and then trimmed down by machine to the required tapering shape. (R.M.W., B.S.M.)

CORK CAMBIUM. **Phellogen.**

CORLISS. **Engine.**

CORM. In botany a corm is a very short, thick, subterranean stem distinguished from the **rhizome** by erect instead of horizontal growth. Its surface shows more or less distinct **nodes.** From the nodes of the upper portion **buds** develop. Generally roots are formed in the lower part of the corm. In many plants the corm is surrounded by scaly leaves or leaf bases. The crocus and the gladiolus produce corms.

In zoology the corm is the median branch or endopodite of the appendage of certain **crustacea** together with the common basal portion. When the exopodite is reduced these parts sometimes appear as the principal axis of the appendage. (R.M.W., A.W.L.)

CORMIDIUM. A group of individuals of various forms budded from the parent stalk of certain floating marine coelenterates. (**Siphonophora.**) (A.W.L.)

CORMORANT. Aves, Pelecaniformes. A large bird (**Aves**) of slender build with a moderately long neck and slender beak, slightly hooked at the tip. The feet are webbed and the birds are strong swimmers and divers. They live entirely on fish. The numerous species are widely distributed, the common cormorant, *Phalacrocorax,* occurring in eastern North America, Europe, Asia, and northern Africa.

In Japan and China cormorants are kept in captivity to be used for fishing. A ring or strap around the bird's neck keeps it from swallowing the fish that it catches, although some are said to be so well trained that they bring fish to their owners without this check.

Cormorants are eaten in some parts of the world. (A.W.L.)

CORN. This term is used in physiology and in botany.

In physiology, a corn is a hard callus or horny thickening of the skin on or between the toes, caused by constant pressure or friction. Beneath the hardened callus there is often a small sac or bursa filled with fluid. A soft corn is one found usually between the fourth and fifth toes, and is formed of thickened moist skin and fibrous tissue.

In botany, corn is a well known plant, Indian Corn or Maize, *Zea mays.* Gramineae. There has been considerable speculation as to the origin of this plant. Everything indicates that it is native to America, probably originating in Mexico. The claim has been made, however, that the Chinese knew the plant before America was discovered, and that the grain was carried from Asia to America during the periods of migration of man from one continent to the other. The evidence supporting this claim is not very strong. The plant is not known to occur in the wild state, but a native Mexican grass, teosinte, *Euchlaena mexicana,* is a closely related grass with which corn **hybridizes** freely. Some botanists hold that teosinte is the ancestral grass from which corn originated.

There are many kinds of corn in cultivation, ranging from dwarf forms less than 3′ high to giant plants 15′ or more in height. All kinds have an extensive fibrous root system, the individual roots not only occupying the surface portion of the soil but also extending downward to depths of 6′ or more. In addition to these normal roots, which all arise from the basal portions of the very young stem, there develop from the lower **nodes** of the older stem prop roots. These prop roots are coarse outgrowths which radiate outward and downward until they reach the surface of the ground. During their growth in the air, their tips are protected from drying by an abundant slime coating; once they have entered the ground they branch abundantly and become like normal roots. They serve to support the plant. The stem of the corn plant is coarse and, unlike other grasses, solid throughout its length. The leaves, borne alternately on the stem, have large broad blades at the base of which is a conspicuous ligule, a membranous outgrowth which tightly invests the stem and so may serve to prevent water entering between the stem and the leaf-sheath. The corn plant is **monoecious,** that is, both staminate (**stamen**) and pistillate (**pistil**) flowers are borne on the same plant. However, they are usually not borne in the same inflorescence. The staminate inflorescence or tassel appears at the top of the plant, and matures some time before the pistillate flowers do. The male flowers produce immense quantities of pollen which when ripe is shed in the air, to be carried by wind currents or gravity to the pistillate flowers. Corn pollen is a cause of hay fever (see **Allergy**) to many people. The pistillate inflorescence, or ear, is a modified branch developing in the axis of a leaf. This branch has a fleshy axis or cob on which are borne rows of pistillate flowers. These occur in two flowered **spikelets,** the lower flower usually being abortive, but its **bracts,** the lemma and palea persisting, as do the two short **glumes** which subtend the entire spikelet. The ovary bears a long style, commonly known as the silk of the corn. When first developed the silk is green and has a sticky surface; after pollination has occurred, the silk

turns brown and dries up. The entire pistillate inflorescence is enclosed in many overlapping modified leaves known as husks, from the tip of which the silk protrudes. The mature corn grain is variously shaped according to the kind of corn. In most species it is a flattened object with a shallow groove on one side, indicating the location of the **embryo.** This embryo is on one side of the grain, the rest of which is filled with a starchy substance, the **endosperm.** This endosperm is usually separable into two parts, one hard and horny, called the horny endosperm; the other less firm and of lighter color, known as the starchy endosperm. The horny portion contains more protein than does the starchy and has its starch grains more densely packed together. The corn grain will not germinate unless the temperature is above 40° F., and sprouts best when the temperature is about 90° F.

Corn is grown most successfully in regions having a deep, warm, well-drained loam soil, an abundance of rainfall and a growing season of ninety days or more, depending on the kind of corn. Improved varieties have been developed which grow satisfactorily in regions having a shorter growing season. Corn is principally grown in the Americas, especially in the United States and Argentina. It has been introduced in European countries and into Africa, but is not grown there to any great extent. In the United States the so-called corn belt grows more than half the entire world crop. This corn belt comprises the states from Ohio west to South Dakota and south to Kansas, a region having climatic conditions most favorable for this crop.

The uses of the corn crop are many and varied. The green plants are fed to stock directly or are stored in silos. For storage in silos the entire plant is cut down and chopped into small pieces. These are compactly stored in large tight structures of wood, concrete or other material, in which partial fermentation occurs, forming a product called ensilage. This is an important part of the ration of dairy cows.

Corn grains form a most important food product for man and his domesticated animals. The ripe ears are picked from the plants and allowed to dry. The grain is then removed from the cob and used directly as stock and poultry food or ground into coarse particles known as cracked corn, much used in feeding poultry. Ground somewhat finer, but still consisting of coarse particles, white corn becomes grits, much used in southern states. More finely ground, corn becomes corn meal, used in making corn bread and various kinds of puddings. Rarely corn is finely ground to flour. Another corn preparation is hulled corn. In making this the grain is soaked in lye which loosens the **pericarp** or outer portion of the grain. This is then removed and the remaining grain cooked soft. As a breakfast food corn appears principally in the form of corn flakes. In making these, clean corn grains are steamed and the hulls and embryo removed, leaving the endosperm. This is sweetened and flavored, and then cooked by steam under pressure. Following this cooking, the grains are partially dried and then passed between heavy rollers, which make them flakes. These flakes are carried to huge ovens where they are quickly toasted. Cooling follows, after which the product is packed in waterproof cases and is ready for the consumer.

In addition to use as food for man and beast, corn yields many important secondary products, such as corn starch, glucose (see **Carbohydrates**) and corn oil. Starch is prepared from corn by soaking the grains in slightly acidulated water for several days, after which they are broken up, the embryos removed and the grain ground. Following the grinding, the whole is passed through sieves which remove the pericarp. The resulting paste is allowed to flow slowly over tilted tables, which allows the starch to settle. This starch is washed and dried, then pulverized for use.

From corn starch is prepared glucose, or corn sirup, a thick substance which results from the partial hydrolysis of starch with acid. The acid is neutralized with sodium carbonate, and the liquor resulting from neutralization is filtered. This liquor is evaporated, and again filtered, emerging as a clear thick sirup, which is boiled down even further. It now becomes commercial glucose, a thick sirupy substance about half as sweet as cane sugar, and with little flavor. It is used in making jellies and preserves, and in blending with other sweets such as cane sirup and maple sirup.

From the embryos of corn, corn oil is prepared. Corn oil is used as a cooking oil and also in making soaps and paints. The cake remaining after the oil is pressed from the embryos becomes a stock food. (See **Esters.**)

Corn stalks have been used experimentally in manufacturing paper. However, the abundance of objectionable non-fibrous material will probably prevent any extensive use of the stalks in this industry. The cobs left after shelling the grain are used as a fuel to a slight extent and also in making cob-pipes. The dried husks form a stuffing for a particularly disturbing kind of mattress, and are also used to some extent as a stuffing in upholstery.

The principal varieties of corn include pod corn, a rarely grown form in which the glumes, lemma and palea of each floret are particularly well-developed, surrounding the kernel; pop corn, in which the sudden explosion of the moisture within the grain turns the latter more or less inside out; sweet corn, characterized by the high sugar content of the grains, and largely grown in home gardens; flint corn, with very hard grains containing a large amount of horny endosperm; and dent corn, so-called because the floury endosperm extends to the end of the kernel and is surrounded laterally by horny endosperm. On maturing the floury endosperm shrinks, causing an obvious dent to appear at the apex of the kernel.

The description above applies to Indian corn or maize, commonly called corn in America and Australia. In Europe the term corn is applied to various cereal grains, in England to wheat, in Scotland and Eire to oats. In its original use corn meant a hard seed or grain. (R.S.M., R.M.W.)

CORN ROOTWORM. Insecta, Coleoptera. Larvae of two species of **beetles.** The adult of one is yellowish green with six black spots on each wing cover. The **larva** of this species, the southern corn rootworm, damages the roots and lower stems of various grains and grasses and sometimes kills the plants. The other species is the western corn rootworm. The adult is entirely yellowish-green and the larva burrows inside the roots of corn and stunts or kills the plant. Both beetles are about 3/8″ long.

The most effective protection against these pests is proper crop rotation. Since the southern rootworm lives on plants other than corn this treatment is supplemented by planting early or late to avoid the most serious attack of the larvae. (A.W.L.)

CORNCRAKE. Aves, Gruiformes. A small shore bird (**Aves**) with long legs and short beak, found in Europe and Asia and occasionally in North America. It is also called the land rail and is related to the Carolina rail of North America. (A.W.L.)

CORNEA. The transparent outer layer of the front of the eyeball. (See **Eye.**) It is a complicated structure composed of five layers. The cornea may be the site of inflammation or ulceration. (D.M.H.)

CORNEAGEN CELL. A kind of cell found in the eyes of some insects. It produces the transparent lenticular cornea at the outer surface of the **eye.** (A.W.L.)

CORNER. A corner is the point of intersection of adjacent property lines. Landed property is ordinarily bounded by broken lines meeting at the "corners" of the property. A land survey is generally a **traverse** with the transit stations at the corners and with the traverse lines coinciding with the property lines. The corners are indicated on a survey plat. They are frequently marked by monuments, either artificial or natural. When subdividing land in accordance with the scheme of the United States **land subdivision,** the corners are designated by standard monuments whose character and markings are governed by certain specific regulations.

If it is impossible to set a monument at a corner, permanent markers called "witness corners" are placed on all lines intersecting at the corner. When a property line intersects a body of water the intersection is marked by a permanent monument known as a "meander corner." (C.W.C., F.T.M.)

COROLLA. **Flower.**

CORONA. Diffraction of light from either the sun or moon through cloud water droplets produces a corona or series of colored rings which appear about the celestial body but actually are at the cloud height. Corona differs from halo in that the latter is due to refraction by ice crystals. Reddish colors always occupy the outer part of the ring. (P.E.K.)

CORONARY OCCLUSION (Coronary thrombosis). Obstruction of a coronary artery, or one of its branches, which supplies blood to the heart muscle. Such obstruction results in death of the heart muscle supplied by the involved vessel.

This vascular accident is a common cause of death between the ages of 45 and 70, although it may occur earlier, in the late 20's or in the 30's. It occurs 3 times as frequently in men as in women. The cause is bound up with the etiology of arteriosclerosis and **hypertension.** Most of the patients give a previous history of **angina pectoris,** and many of them have high blood pressure.

Pathologically, the coronary artery is seen to be occluded by a thrombus, or plug, formed by an arteriosclerotic process in the lining of the vessel. Gradual narrowing of the vessel along its course may also result in coronary occlusion.

Clinically, the chief symptoms and signs are those of pain and **shock.** The pain is sudden, severe, and constricting, located beneath the sternum or over the heart. Unlike the pain of angina, it is not related to exertion or activity, and instead of being brief, it lasts for hours or occasionally, days. Shock is manifested by an ashen-gray color, cold sweating skin, thready pulse, and a fall in blood pressure. Nausea and vomiting may occur. The diagnosis may be confirmed by an **electrocardiogram** which demonstrates characteristic patterns.

Treatment in the acute phase consists of the administration of **morphine** to relieve the pain and the anxiety (fear of impending death is common); aminophylline intravenously and **oxygen** inhalation are also useful.

The immediate mortality is about 40%. Many patients who die suddenly are said to have "acute indigestion" because the pain may be epigastric, and nausea and vomiting often occur. If the patient survives the first few weeks, sufficient recovery will usually take place to allow him to lead a life of restricted activity. (D.M.H.)

CORONATAE. An order of jellyfishes (**Scyphozoa**) with a lobed margin. Found in the open ocean. (A.W.L.)

CORPUS CALLOSUM. A broad band of nerve fibers within the **brain,** connecting the two cerebral hemispheres. (A.W.L.)

CORPUS LUTEUM. **Sex Hormones; Menstruation.**

CORPUSCLE. A term applied to many minute bodies. 1. The **cells** of the **blood.** 2. The excretory unit of **vertebrates,** consisting of a small knot of blood vessels enveloped by a capsule. **Renal corpuscle.** 3. Bone cells are called corpuscles of Purkinje. 4. Many nerve endings including Pacinian or lamellar corpuscles, Grandry's corpuscles, tactile corpuscles. These and all other sensory corpuscles consist of nerve endings enveloped by accessory cells of various forms. They are sensory organs. (A.W.L.)

CORRASION. This term is applied to the mechanical wearing away of rocks through the agency of running water and the rock fragments which it carries in suspension. (R.M.F.)

CORRELATION. Two **variables** are said to be correlated if there exists any dependence between them. If the **probability function** of the two variables P_{x_1, x_2} is related to the probability function of each variable x_1 and x_2 by the relationship

$$P_{x_1, x_2}dx_1dx_2 = P_{x_1}dx_1 \cdot P_{x_2}dx_2,$$

then the two variables x_1 and x_2 are independent. Otherwise the variables are correlated. The nature of the dependence may be so complete that knowing the value of one variable we may predict the value of the other variable, or the dependence may be of any amount from the case of complete dependence to that of independence. It should be noted that neither variable is more important than the other variable but that the relationship of dependence is mutual. Correlation may indicate either a causal relationship or may be merely one of association. The idea of correlation may be extended to any number of variables. Types of correlation are **linear, multiple, curvilinear.** The functional relationship $y = f(x_1, x_2, x_3)$ in the case of three variables is said to be the **regression** of y on x_1, x_2 and x_3. The degree of correlation may be measured by the **coefficient of correlation,** the **index of correlation,** the **coefficient of multiple correlation,** the **index of multiple correlation,** and the **correlation ratio.** (L.A.A.)

CORRELATION RATIO. The correlation ratio of y on x, η_{yx}, is defined by

$$\eta_{yx}^2 = 1 - \frac{\sigma_{ey}^2}{\sigma_y^2}, \quad \sigma_{ey}^2 = \frac{\Sigma(y - \bar{y}_x)^2}{N},$$

σ_y^2 is the **variance** of y, N = number of paired **variates,** and $\bar{y}_x$ is the **mean** of a column for a particular value of x. This may be written as

$$\eta_{yx}^2 = \frac{\Sigma N_c(\bar{y}_x - \bar{Y})^2}{\Sigma(y - \bar{Y})^2},$$

$\bar{Y}$ = mean of the y's, N_c the number of items in a column for a particular value of x For computational purposes

$$\eta_{yx}^2 = \frac{N\left[\sum_{c=1}^{c} \frac{\left(\sum_{1}^{N_c} f_{xy}d'_y\right)^2}{N_c}\right] - (\Sigma f_y d'_y)^2}{N\Sigma f_y d'^2_y - (\Sigma f_y d'_y)^2},$$

c is the number of columns, $\sum_{1}^{N_c}$ is a summation over a column, $N = \sum_{c=1}^{c=c} N_c$, d'_y is a **deviation** from an arbi-

trary origin in class intervals, f_{xy} is the frequency in a cell. The range of values for η_{yx}^2 is $0 \leq \eta_{yx}^2 \leq 1$ and always $\eta_{yx}^2 \geqq r_{xy}^2$. It should be noted that the **index of correlation** is defined in essentially the same way as η_{yx} but η_{yx} is always obtained from a correlation table. We test the hypothesis that $\eta_{yx}^2 = r_{xy}^2$, r_{xy} being the linear **coefficient of correlation,** by use of the **analysis of variance**

$$F = \frac{\eta_{yx}^2 - r_{xy}^2/c - 2}{1 - \eta_{yx}^2/N - c}$$

with $n_1 = c - 2$, $n_2 = N - c$ and refer to tables of **Snedecor's *F* distribution.** To find η_{xy}^2, x and y are interchanged. (L.A.A.)

CORRELATION SURFACE. The correlation surface $z = P(x_1, x_2), z \geqq 0$, is a surface depending on the two **variables** x_1 and x_2. The volume under the surface $P(x_1, x_2)\Delta x_1 \Delta x_2$ represents approximately the **probability** that x_1 shall have a value between x_1 and $x_1 + \Delta x_1$ simultaneously with x_2 a value between x_2 and $x_2 + \Delta x_2$. This generalizes for more than two variables, say m, to $z = P(x_1, x_2, x_3, \cdots, x_m)$, $z \geqq 0$, and the volume $P(x_1, x_2, \cdots, x_m)\Delta x_1 \Delta x_2 \cdots \Delta x_m$ is interpreted as the probability that x_i will have a value between x_i and $x_i + \Delta x_i$, $i = 1, 2, \cdots, m$. The **moments** of $x_1, x_2, \cdots, x_m$ and the **higher moments** would be found in the usual way, depending on the **discrete** or **continuous** nature of the **variates.**

We briefly describe the normal probability function or surface in two variables. The corresponding generalization in m variables, the multivariate distribution will not be discussed. In the case of two variables in **standard units** t_1, t_2

$$z = P(t_1, t_2, r) = \frac{1}{2\pi\sqrt{1 - r^2}} \exp. - \frac{t_1^2 - 2rt_1t_2 + t_2^2}{2(1 - r^2)},$$

$$-\infty < t_1 < \infty \quad -\infty < t_2 < \infty.$$

$t_1 = \dfrac{x_1 - \bar{X}_1}{\sigma_{x_1}}$, $t_2 = \dfrac{x_2 - \bar{X}_2}{\sigma_{x_2}}$, r the **coefficient of correlation** between t_1 and t_2. Then the simultaneous probability that $a_1 \leq t_1 \leq a_2$, and $b_1 \leq t_2 \leq b_2$ is given by the double integral

$$\int_{t_1=a_1}^{t_1=a_2} \int_{t_2=b_1}^{t_2=b_2} P(t_1, t_2, r)dt_1dt_2.$$

The **regression** of t_1 on t_2 is given by $t_1 = rt_2$, i e., the locus of the **mean** value of t_1 is a straight line. Similarly $t_2 = rt_1$ is the regression of t_2 on t_1. The plane $t_2 = a$ intersects $P(t_1, t_2, r)$ in a **normal curve,** and similarly for a plane $t_1 = b$. A plane $z = c$, $0 \leq c \leq \dfrac{1}{2\pi\sqrt{1 - r^2}}$ intersects $P(t_1, t_2, r)$ in an ellipse. When $r = 0$

$$P(t_1, t_2, r) = P(t_1) \cdot P(t_2) = \frac{1}{\sqrt{2\pi}} e^{-\frac{t_1^2}{2}} \cdot \frac{1}{\sqrt{2\pi}} e^{-\frac{t_2^2}{2}}.$$

In the limit as r approaches 1, $P(t_1, t_2, r)$ approaches a normal curve in the plane $t_1 = t_2$. Volumes under the surface $P(t_1, t_2, r)$ have been calculated. It should be noted that $P(t_1, t_2, r) = P(t_2, t_1, r) = P(-t_1, -t_2, r) = P(t_1, -t_2, r) = P(-t_1, t_2, -r)$. (L.A.A.)

CORRESPONDING STATES. Critical State.

CORRODENTIA. An order of minute **insects** containing the **book lice** and psocids. They have biting mouths and some species bear four wings. Some are found among plants and on bark and others frequent books and papers, especially in damp buildings. (A.W.L.)

CORROSION. The most common kind of corrosion, with which everyone is familiar, is that of *rusting*. This is but a special case of a general classification known as atmospheric corrosion, wherein the oxygen of the atmosphere reacts with the material in question. Most metals, with the exception of the noble metals, such as gold, can be oxidized by atmospheric oxygen. In the usual case, however, water vapor must be present before any appreciable oxidation can take place. With iron, for example, 40% humidity is needed at ordinary temperatures before rusting will occur.

Corrosion which takes place when materials are immersed in solutions cannot be explained by any single rule. Several different explanations are required for a complete understanding of the phenomena. All substances are soluble to some extent in water. When a piece of iron is put into water it will immediately begin to dissolve in the water in the form of actual metallic iron (Fe) in solution. If there is oxygen present in the water, the oxygen will immediately attack the iron in solution oxidizing it to ferric hydroxide. The hydroxide will precipitate, thereby removing the iron from the solution, which allows more iron to dissolve. Obviously, in order to have the process continue to the ultimate wearing out of the iron, the supply of oxygen must be continually renewed.

The acidity of the water has a great effect on the speed and the degree to which the material can be dissolved. In this regard, carbon dioxide plays an important rôle. It is dissolved in the water from the atmosphere and forms carbonic acid, which makes the water slightly acidic. Because the acidity is quite low, its concentration, if put in usual chemical terms, would be insignificant. The pH system of expressing concentration, wherein the pH of a solution is the logarithm of the reciprocal of the hydrogen ion concentration, is commonly used. Using this system, the pH number is somewhere between 1 and 14. Neutral solutions have a pH of 7. A pH less than 7 means that the solution is acidic and more than 7 means that it is alkaline.

When a metal becomes corroded because of the acidity of the solution in which it is immersed, the process of solution is different from the one mentioned previously. In this case the substance goes into solution because there is an interchange of hydrogen ions in the solution with the atoms of the metal in the piece. The metal goes into solution and hydrogen tends to plate out on the piece. As soon as the piece has a film of hydrogen on its surface the dissolving of the metal will cease. Here again, oxygen plays an important part, because the oxygen dissolved in the water will react with the film of hydrogen to eliminate it by forming water and allow the corrosion reaction to proceed.

Another type of corrosion is called concentration cell corrosion. It is known that two solutions of different concentrations will set up an electrical potential between them similar to that produced by a battery. If oxygen is present in the liquid and it is continually being replenished by contact with the air, then the oxygen concentration in the liquid will remain substantially constant. Any liquid that is contained in small holes or cracks on the metal surface will not be able to obtain oxygen from the main bulk of the solution, so when the supply in the holes and cracks is exhausted, no more oxygen can get in to replace it. Therefore the oxygen concentration in the cracks is different from that of the main bulk of the solution and a concentration cell is set up. This minute electrical effect is sufficient to make corrosion proceed quite rapidly.

A similar cell type of corrosion is that called galvanic or two-metal corrosion. Two different metals in contact will set up an electrical potential between them. If the two metals are surrounded by an electrolyte so that a closed circuit can be obtained, corrosion takes place. The magnitude of the electrical potential and therefore the speed and extent of the corrosion will depend upon the types of metals in each pair. In general, pairs farther apart in the electromotive series will corrode faster than those closer together.

Certain alloys consist of more than one kind of crystal. When these alloys are exposed to a conducting solution, corrosion tends to take place wherever two dissimilar crystals are together and in contact with the solution. Here the size of the crystals is an important factor in whether or not corrosion will take place. Because particle size can be changed by proper heat treatment, it is sometimes possible to make an alloy more corrosion-resistant by giving it a heat treatment before use. Very large or very small crystals will not corrode as fast as intermediate sizes.

When a piece of metal is under strained conditions its properties are usually different from those when it is not strained. There are certain cases where corrosion has taken place in a metal which was homogeneous, but corrosion started at the point where the metal was known to be in the most strained condition. It is believed that here also an electrical potential may be set up between the strained and the unstrained metal.

The obvious way to prevent oxidation is to prevent the oxygen from getting into contact with the surface. In a steam boiler this is done by heating the water before it enters the boiler, thereby driving out the dissolved oxygen.

Because the acidity of a solution contributes largely to the speed of the corrosion, the acidity may be reduced by the addition of alkaline agents, or the solution may be "buffered" by the addition of certain salts. Buffering is the process of depressing the hydrogen ion concentration by using the proper concentrations of other substances.

If oxygen cannot be eliminated from the solution and if the acidity must remain at a certain fixed value, then occasionally inhibitors can be found to prevent corrosion. Inhibitors are substances which are put into a solution in a small amount to stop the corrosion. They fall in two general classes, namely, (1) substances which show a "preferential wetting" effect, that is to say, the inhibitor will wet the surface of the metal easier than will the solution. Therefore the inhibitor will spread over the surface of the metal and effectively keep the solution from attacking it; and (2) substances which either stabilize the natural protective coating on the metal or which react with the metal to form a coating. For example, if the metal has a tendency to form an oxide film, then a solution which has a small amount of oxidizing material in it such as a dichromate will allow oxide film to persist, thereby protecting it against corrosive action. When a natural protective film such as an oxide is on a metal it is spoken of as being in the "passive" state; when the solution is such that it destroys the protective film then the metal is said to be in the "active" state.

All metals with the exception of the noble metals form oxide coatings. Some of these, such as the coating on aluminum, lead, or copper give protection from corrosion. Under the proper conditions an oxide film can be put on iron to give a considerable measure of protection. This process is called "bluing." Information on the protection of metals by paint and other artificial coatings may be found under **Protective Coatings, Pigments, Paints,** and **Varnishes.**

The term is applied by mineralogists and petrologists to the resolution and modification of the crystal form of **phenocrysts** during their growth in the parent **magma.** The same term is also used by some geologists and **physiographers** to denote the mechanical erosion of the surface of the earth, particularly by rivers and glaciers. A better term for this purpose, however, is **corrasion.** (D.E.M., R.M.F.)

CORROSION, PROTECTION AGAINST. In combating corrosion, the surface of the metal may be protected by **paints,** plates, or other surface coatings. Or again, the metal may be **alloyed** in such a way as to render it corrosion-resistant. In most cases corrosion is merely a slow, obvious destruction of investment in a metal, but there are instances where the potential destructive action greatly exceeds that caused by the corrosion alone. For example, in pressure vessels such as the steam boiler, corrosion in the boiler itself may hold potential threat of destruction for an entire plant, and endanger lives. It is possible for corrosion to occur at many places in the piping leading to boilers or heaters, but usually it occurs in the boiler itself. The trouble is ordinarily found to be due to an acid condition of the boiler feed water, or to dissolved oxygen contained by it. The raw water used may be acid from surface pollution or from sub-surface drains. Usually this can be detected and readily remedied. A more serious factor is the oxygen dissolved in water. Under the high-temperature conditions existing in the boiler itself, this oxygen becomes extremely active in attacking metal surfaces. The operators of large high-pressure boilers well know the necessity of removing oxygen from feed water through the employment of deactivators or deaerators.

The ordinary user of a metal has at his disposal several means for minimizing corrosion. One of the more common is the application of a protecting surface of corrosion-resisting metal. **Zinc** is one such metal. Galvanized iron is iron with a thin layer of zinc applied to it by dipping in molten zinc or by electrical means. Cadmium, nickel, tin, and chromium are metals often used as protective coatings, generally applied by **electroplating.** (F.T.M.)

CORROSIVE SUBLIMATE. Mercury.

CORSITE. An orbicular **diorite** resulting from the segregation, in rounded concentric forms, of ferro-magnesian minerals (see **Iron** and **Magnesium**). It derives its name from its occurrence on the Island of Corsica, and is also sometimes called Napoleonite. (E.S.C.S.)

CORTEX. This is the outer portion of a **stem** or **root,** bounded externally by the epidermis, and internally by the cells of the pericycle. It is composed mostly of **cells** which are very little differentiated. Usually these are rather large, thin-walled **parenchyma** cells. The outer cortical cells often acquire irregularly thickened cell walls, contain **chloroplasts,** and carry on **photosynthesis.** These are the collenchyma cells.

In zoology, a superficial layer of an organ. Included are such organs as the kidney, the adrenal gland, the ovary, the thymus and portions of the brain. Among these examples the cerebral cortex of the brain is the most familiar. The term designates no common characteristic of origin or structure, but only the existence of a distinctive layer at the surface of the organ involved. (B.S.M., A.W.L.)

CORTLANDTITE. Peridotite.

CORUNDUM (Ruby) (Sapphire) (Emery). The mineral corundum, Al_2O_3, **alumium** oxide, occurs as well-developed **hexagonal** crystals which may display prismatic, rhombohedral, pyramidal or tabular habits. The larger crystals are often rounded or barrel shaped. Corundum shows both basal and rhombohedral partings; the fracture is conchoidal; hardness, 9; specific gravity, 3.95–4.10; luster, vitreous to adamantine, may be pearly on base; transparent to translucent. Common corundum is gray, grayish-blue or brown, but may be red, yellow or whitish; it is sometimes called adamantine spar. Transparent corundum may be colorless or of various tints. The highly prized ruby is deep red, the sapphire, blue. Transparent yellow corundum is known as oriental topaz; if violet, oriental amethyst; if green, oriental emerald.

Emery is a mixture of granular corundum of dark color, magnetite and hematite, sometimes with spinel. **Quartz** may be present. For a long time emery was

supposed to be an ore of iron. Until the introduction of artificial abrasives emery was much used for such purposes.

Corundum is found as an accessory mineral in the crystalline rocks such as crystalline **limestones** and **dolomites**, **gneisses**, **schists** as well as in the **igneous rock** types **granite** and **syenite**. Corundum syenites are found in Canada, especially in the Province of Ontario. Rubies have long been mined in Upper Burma; both rubies and sapphires are found near Bangkok, Siam. Numerous localities in India furnish gem stones of high quality.

In the United States common corundum is found in New York, New Jersey, Pennsylvania, Virginia, North Carolina, South Carolina and Georgia. Sapphires of gem quality near Helena, Montana, associated with alluvial gold in the Missouri River. From the crystalline limestones and schists of the islands of Naxos and Samos in the Grecian archipelago most of the emery of commerce comes. Other deposits are near Ephesus in Asia Minor, and in the town of Chester in Massachusetts. The word corundum comes from the Hindu, *kurand;* emery is derived from the Greek name for this substance. (E.S.C.S.)

CORVUS. (The raven or crow.) (Map, page 380.) Corvus is a small **constellation** containing no particularly bright or interesting stars. This group of stars has long been a friend to lovers of the sea because of its resemblance to the "fore and aft" sail of a cutter. For this reason the constellation is frequently referred to by sailors as "the cutter's mainsail." On a clear moonless night the resemblance to the sail is very remarkable, even the "step" of the mast and a small "pennant" flying from the gaff being discernible. (W.K.G.)

CORYDALIS. Insecta, Neuroptera. A large gray **insect** with four membranous wings and in the male sex with very long slender jaws. The adult of the **hellgrammite.** Also called dobson fly.

In botany, the term Corydalis is applied to a genus of plants occurring in the north temperate regions and in South Africa, which are sometimes found in cultivation. All are herbs with small, somewhat irregular flowers. (A.W.L., R.M.W.)

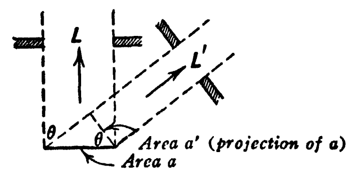
CORYMB. Flower.

CORYZA. Acute coryza or the common cold is a catarrhal inflammation of the upper respiratory tract of unknown origin but probably caused by a filterable virus (see **Filterable Virus**). Various descriptive terms are used, depending upon the particular portion of the tract involved, such as acute rhinitis, when the nose is involved primarily, acute pharyngitis or acute laryngitis.

Experiments indicate that chilling may precipitate an attack. Susceptibility to infection is increased when the body is exposed to such sudden changes in temperature as may produce localized cooling of nose and throat.

Diseases of the upper respiratory tract are often highly contagious and spread rapidly. There is a definite seasonal variation of incidence, the peak usually occurring during the winter months. The common cold in itself is not dangerous, but measles is frequently ushered in by an acute coryza, and pneumonia may be preceded by it. (D.M.H.)

COSINE EMISSION LAW. A law relating to the emission of **radiation** in different directions from a radiating surface. If a small, white-hot metal plate is viewed from a great distance, its apparent candle power, measured by a photometer, is greatest when it is perpendicular to the line of sight, and reduces to practically zero when it is turned edgewise. If the observer now moves nearer, he finds that this change is due to the smaller angle subtended by the surface, that is, the smaller cross-section of the beam proceeding from it in his direction; and that the apparent **brightness** of the surface is the same however it is turned. To apply this, let the radiating surface, of area a, be emitting a luminous flux L (lumens) in the normal direction (see figure), and, in any other direction making an angle



Illustrating cosine emission law.

θ with the normal, the smaller quantity L'. Then since the apparent brightness is unchanged, $L'/a' = L/a$. This gives $L'/L = a'/a$. But $a'/a = \cos\theta$, hence $L' = L\cos\theta$; which means that the energy emitted in any direction is proportional to the cosine of the angle which that direction makes with the normal. This is the "cosine emission law" of Lambert. It applies to thermal radiation as well as to light, and to diffusely reflected as well as directly emitted radiation. The law is true only for a perfectly diffusing surface, strictly, for a **black body.** (L.D.W.)

COSINE-HAVERSINE FORMULA. Celestial Navigation.

COSMETICS. The term cosmetic means (1) articles intended to be rubbed, poured, sprinkled, or sprayed on, or introduced into or otherwise applied to the human body or any part thereof for cleansing, beautifying, promoting attractiveness, or altering the appearance, and (2) articles intended for use as a component of any such articles; except that such term shall not include soap. Face powders, lipsticks, nail polishes, cleansing creams, bath powders are cosmetics. The distinction between a cosmetic and a drug is brought out by this part of the definition of a drug, namely, articles (other than food) and components of such articles that are intended to affect the structure or any function of the body of man or other animals. Some commonly accepted cosmetics qualify, therefore, as drugs as well, for example, antiperspirants since they affect the functions of the sweat glands, and hair preparations that claim to treat dandruff, since the claim made for an article has an important legal bearing. Furthermore, a cosmetic preparation is deemed to be adulterated, and consequently to be in violation of the Federal Food, Drug, and Cosmetic Act of 1938, if it contains any "poisonous or deleterious" substance, a statement that clearly excludes the use of mercury-, arsenic-, cadmium-, selenium-, or thallium-containing substances, and amines (not ethanolamines).

Face powder is a blend of (1) white pigments, (2) sufficient coloring materials to give the desired tint, and (3) perfumes. By virtue of its covering power, face powder hides the color of the part of the body to which it is applied, and gives this part the color of the face powder. Some covering agents used are zinc oxide (22), titanium oxide (10), magnesium carbonate (20), magnesium stearate (20), zinc stearate (20), kaolin (20) or clay, talc (80), calcium carbonate (20) or precipitated chalk, and rice starch (40), where the numbers in parentheses signify the relative amounts required to produce the same shade with a given amount of coloring material (thus talc is the poorest and titanium oxide the best covering material). In the matter of adhesiveness or staying-on power, some combination of stearates, palmitates, or myristates of magnesium, zinc, and aluminum are frequently used—a common recipe is about 4% of magnesium or zinc stearate. To produce smoothness in face powder, both in use and in handling, talc is unique, and is usually used to the extent of one-half or more of the products. White pigments that are

used to absorb perfume are precipitated chalk, starch, magnesium carbonate, and kaolin, which pigments may be thus used up to 10% of the product. The coloring materials are either natural ground earth colors or else organic colors certified under the previously mentioned Act of 1938. (See **Dyes and Dyeing Textile Fibers.**) Color is considered a primary factor in face powders. Perfumes (see same) are added after the talc has been "prefixed" by a special treatment involving a chemical treatment followed by ageing.

Talcum powders are essentially like face powders, but baby talcum powder is borated by the addition of powdered boric acid, and also treated with an antiseptic material. So-called "liquid powder" requires the presence of some mucilagenous substance for adherence, and bentonite clay to aid in maintaining the solids in suspension and to prevent caking on standing.

In the preparation of cold cream, part of the fatty acid component of beeswax is allowed to react with borax in hot solution to form a soap, essentially sodium cerotate, plus boric acid. An oil-in-water emulsion of the excess beeswax or other oil or fat results. A very general type of recipe uses approximately 1 part by weight of beeswax, 2 parts of water, and 3 parts of other oil or fat, such as mineral oil, almond oil, spermaceti, ceresin, or lanolin. Borax is used to react with some 5% of the beeswax, say 1 part borax to 16 parts beeswax. Instead of beeswax there are used such materials as triethanolamine, the glycerides or glycols of fatty acids, for example, glyceryl or glycol monostearate, or fatty acid ester of mannitol or sorbitol. Perfumes, antioxidants, and preservatives are added ingredients. Vanishing cream contains stearic acid (approximately 15%), sodium or potassium stearate (5%), glycerol (8% or less), and the remainder water.

Lotions are (1) water plus mucilage emulsions containing up to say 3% of mucilage of quince seed, tragacanth, karaya, psyllium, Irish moss, or linseed with a small percentage (say 3 to 10) of alcohol; or (2) alcohol solutions containing 35% or more of alcohol for use as astringents or body rubs. About 2 parts by weight of zinc sulfocarbolate (phenolsulfonate) in 50 parts of alcohol and 50 parts of water, with perfume added, is a popular astringent lotion. Hand lotion is commonly 25% glycerol and 75% rose water, but the addition of such materials as triethanolamine (1%) or sorbitol stearate (1%) is practiced.

The essential ingredients of lipstick are (1) an oil, (2) a wax to make the oil semisolid, and (3) coloring materials, usually of two kinds (a) soluble dibromo- or tetrabromofluorescein, called bromo acid, and (b) insoluble color lakes certified in the Act of 1938. Castor has been the favorite oil used, but the fatty acid esters of glycerol and of glycol seem to have some advantage over castor oil in the matter of increased solubility for bromo acid, as well as less likelihood to produce allergic results. The bromo acid content is commonly of the order of 1 to 3%, and the colored lakes about 10%. The product is blended so that it is easily applied, does not separate or sweat, does not crack or crumble, and stays on satisfactorily for several hours. It must not be irritating to the flesh, and should have a softening point not lower than 48° C. (118° F.) nor higher than 63° C. (145° F.), the favored range being 55 to 60° C. (131 to 140° F.). Mineral oil, 15% in amount, imparts gloss, but has no other useful function. The flavor and odor are also important, and are decidedly limited in choice—coumarin, methyl coumarin, vanillin, and ethyl vanillin for flavor, and rose, jasmin, and orange blossom for odor—with the total amount of both about 2% only.

Nail lacquer and nail lacquer remover are two cosmetics closely related to larger chemical industries, since the lacquer is not unlike quick-drying **lacquers** based on nitrocellulose dissolved in the proper organic solvent, and the lacquer remover performs the same function as an ordinary lacquer remover such as acetone or ethyl acetate. Addition is required of appreciable amounts of softener or plasticizer, even in amount equal to the nitrocellulose content, to avoid brittleness of the film; of resin to improve the adhesion of the film to the nail, and to improve gloss; and of coloring materials, as discussed under other cosmetics. (R.K.S.)

COSMIC RAYS. A highly penetrating radiation apparently reaching the earth in all directions from outer space. The existence of this radiation was first suspected from the discharge of **electroscopes** in air free from all known ionizing influences, the rate of discharge increasing as the electroscope was carried to higher altitudes. (See **Ionized Gases.**) The atmosphere apparently absorbs a measurable portion of the rays, but traces of their effect persist even at depths of many feet below water or below the ground. Professor R. A. Millikan and his associates, who have studied the distribution and absorption of the rays very thoroughly, find that the rays are of nearly the same intensity from all parts of the **celestial sphere,** and that, as they proceed through an absorbing medium, they show evidence of unequal absorption rates. Professor A. H. Compton and many others have expressed the view that the rays are not of any one type, being probably in part true radiation and in part corpuscular, like radioactive emissions, and that they are influenced by the earth's magnetic field.

Observations on the cosmic rays have been extended to nearly all parts of the earth's surface and many miles up into the atmosphere. The most common detector is the electroscope, special forms of which, with automatic recording devices, have been perfected for the purpose. Also used are various types of **counting tube** or ion counter and the Wilson **cloud chamber.** Dr. T. H. Johnson and others have devised ingenious arrangements of counters by means of which it is possible to trace the actual path of a single cosmic particle or photon. At present it is not possible to be sure whether a supposed cosmic particle is really part of the original rays or is a result of cosmic-ray action upon atmospheric molecules. (See **Secondary Emission.**)

The origin of the cosmic rays is still entirely unknown. Attempts to trace them to the **sun,** the **stars,** or to other recognizable celestial objects, have been equally unsuccessful. Millikan advanced the theory that the rays are a result of the synthesis of certain types of **atom** in outer space and that they represent the "mass defect" energy of these atoms. This was when the rays were supposed to be purely **electromagnetic radiation.** More recently Millikan and his associates have ascribed the rays to the transformation of the "rest mass" of interstellar atoms (see **relativity**) into electron pairs of enormous energy. At present their complex character renders the question of their origin exceedingly difficult. (L.D.W.)

COSMOGONY. **Milky Way; Historical Geology.**

COSTAL. This term means pertaining to a rib or the region of the ribs. Thus, costal cartilage is the cartilaginous portion of the ribs which joins them to the **sternum.** The term intercostal refers to the space between the ribs. (R.S.M.)

CO-TERMINAL ANGLES. **Angles.**

COTINGA. Aves, Passeriformes. A group of Brazilian **chatterers** closely related to the bell birds. (A.W.L.)

COTTER. A wedge-shaped metal piece for fastening two parts subjected to reciprocatory motion. The connecting rod bearing of a steam engine is often constructed with a removable cap held in place by a cotter. A cotter

pin (see Fig. 2, screw fastenings) is a split pin made of semi-cylindrical bar stock, bent so that the flat surfaces are in contact, to permit insertion in a drilled hole. The cotter pin is used as a locking medium for nuts and bolts; since the pin is made of a soft steel, the split ends can be spread after it has been inserted in the hole. (H.C.H.)

COTTON. *Gossypium* species. Malvaceae. Many species of cotton plants are known, some native to warm regions of America, others growing wild in tropical Asia. Cotton seeds are surrounded by an abundance of soft white fibers which when mature are very conspicuous. These fibers are unicellular and have been known and used by man for years. Cultivation of cotton in India has continued through twenty-six centuries. Even before the discovery of America the natives of tropical America were growing Sea Island cotton and using its fibers. At present the United States leads the world in cotton production, but other countries are rapidly increasing their production as demand for the product grows. Brazil, Egypt, and India are important producers.

The cotton plant of cultivation is a woody annual growing three or four feet tall. It bears large palmate leaves and showy white flowers which turn pink as they grow older. Outside the 5-parted **corolla** and **calyx** is an involucre composed of three large green **bracts** having very irregular margins. These bracts persist throughout the growth of the fruit. The **stamens** of the cotton flower have their filaments united to form a hollow tube through which the stigmas must grow; this stamen structure is characteristic of the mallow family, or Malvaceae. The fruit is a large dehiscent capsule of ovoid shape. On dehiscence, or splitting open, at maturity, the soft white fibers which surround the five or six large dark brown or black seeds become visible. The fibers are of two kinds, one relatively long, called lint, the other short and called fuzz. The capsule of the cotton plant is generally called the cotton boll. The length of the lint fibers varies in different species: Sea Island cotton, the native American species *Gossypium barbadense,* cultivated on coastal areas of the southern states, has the longest fibers of any cotton (1½–2½″ long). Egyptian cotton fibers are slightly shorter than these. Next comes upland cotton, which is mainly derived from *Gossypium hirsutum.* This is the principal cotton plant of the southern states. In these the length of the fibers varies considerably, but averages about 1″. Asiatic cottons have still shorter fibers.

Cotton cultivation is limited to regions having a growing season of 6 months or more of continuous high temperature. Any soil having a proper moisture content is suitable for cotton, but a deep, well-drained loam soil is best. One requirement is that excessive rainfall shall not occur during the period when the bolls are opening, since the cotton fibers are injured by moisture at that time. During the growing season the cotton fields must be kept clear of weeds. From 5 to 6 months is required before the production of fibers begins, after which fiber production continues for another 3 months or more.

Picking of the lint and contained seeds is done almost entirely by hand, and requires much cheap hand labor during the picking season. Recently machines have been introduced which bid fair to replace human labor. The soft light fibers, after picking, are carted to the gins. Previous to the invention of the cotton gin by Eli Whitney in 1793, the lint was removed from the seeds by hand, a slow and laborious process. The invention of the gin greatly advanced the cotton-manufacturing industry. The cotton gin of today is essentially the same as that of Whitney, a steel grate with narrow slits through which reach thin notched saws. The rapid rotation of the latter causes lint to catch on their teeth. The lints are pulled through the grating, after which brushes remove them from the saws. This ginned cotton is then pressed into bales weighing about 500 lbs. each.

The uses of cotton are many. First among them is the manufacture of cloth. In this, cotton ranks first among textiles, far exceeding any other fiber. Cloth may be woven entirely of cotton, as much is, or may be of cotton mixed with other fibers, as silks, linen and wool. Cotton fabric forms an important part of automobile tires, being the base on which the rubber is held.

Cotton fibers, especially the fuzz, are frequently used to stuff mattresses, pads and upholstered furniture. Treated with chemicals which remove the thin coating of waxy substances which cover the fibers, the latter becomes **absorbent cotton,** which is capable of absorbing many times its weight of water.

Cotton treated in this way is almost pure **cellulose,** and so is in great demand by those industries using cellulose. The pure cellulose of the fiber may be dissolved and then precipitated in sheets, giving the familiar thin transparent cellophane. Or the dissolved cellulose may be pressed through fine holes and solidified, giving rayon or artificial silk. If treated with concentrated caustic soda, cotton fibers take on a high degree of luster, resembling silk. The product of this process is called mercerized cotton, after John Mercer, its discoverer.

Treated with nitric acid under various conditions, cotton yields a long series of by-products. Some of them are plastic substances known as pyroxylins. If highly nitrated, cellulose becomes guncotton, used in the manufacture of explosives. So-called artificial skin or collodion is one of these nitrated products. Many varnishes and lacquers of recent development are made from cotton cellulose.

Not all the derivative products of cotton come from the fibers. Some, for example, are obtained from the seeds. In preparing these, the hulls are first removed from the kernel within. These hulls are used as fuel in the ginning mill, as food for cattle, and as fertilizer. The kernels are heated and pressed to remove the oil in cotton. During this pressing the kernels are wrapped in cloth to prevent anything but oil from being expressed. The oil is purified to a soft white substance very similar to lard in appearance. Cottonseed oil is used in making salad oils, butter substitutes, and soap. (See **Esters.**) After the oil is expressed, the seed cake may be used as food for stock or as a fertilizer. (R.M.W.)

COTTON STAINER. Insecta, Hemiptera. *Dysdercus.* A **bug** of Florida and adjacent states which punctures the bolls of cotton and causes staining of the fiber. It develops in groups which can be jarred from the plants into vessels containing a little kerosene. (A.W.L.)

COTTONMOUTH. Reptilia, Sauria. A poisonous **snake,** *Agkistrodon piscivorus,* of the southeastern United States. Named from the whitish color of the inside of the mouth. It frequents wet places, especially swamps, and is sometimes called the water moccasin.

This species is a pit viper, related to the copperhead and rattlers. It reaches a length of 6′ and is more aggressive than the copperhead but is said to be less deadly than popularly supposed. Treatment of its bite is the same as for other **pit vipers.** (A.W.L.)

COTTON-MOUTON EFFECT. Electric and Magnetic Double Refraction.

COTTONTAIL. Mammalia, Rodentia. *Sylvilagus.* Wild **rabbits** of several variable species, distributed from southern Florida to Mexico and north into Canada. They are gray to brown and most forms have the tail white beneath. An included species is the pontoon or marsh rabbit of Dismal Swamp. The cane cutter or swamp rabbit of the south central states is another species that inhabits wet ground. (A.W.L.)

COTYLEDON. Seed.

COTYLOSAUR. Fossil Reptiles.

COUCAL. Aves, Cuculiformes. Ground birds (**Aves**) of several species, black or red and black in color, found in the Oriental, Australian, and Ethiopian regions. **Cuckoos.** (A.W.L.)

COUDÉ. The Coudé is a modification of the **equatorial** form of mounting for an astronomical telescope designed for the purpose of providing a maximum amount of comfort for the observer. The telescope itself is mounted in bearings parallel to the axis of rotation of the earth and forms the polar axis of the instrument. The eyepiece is at the upper end and usually projects into a closed room. Below the object glass a mirror is mounted in such a manner that it may be rotated about an axis perpendicular to the optic axis of the telescope. Hence the mirror may be rotated about its own axis parallel to an **hour circle** (in the coordinate of **declination**) and is carried along with the rotating tube parallel to the coordinate of **hour angle.** As the observer is seated in a comfortably heated room he looks down into the eyepiece and sees the field of view slowly rotating about the optic center of the field.

The fundamental difficulty with the Coudé mounting may be traced to the fact that the mirror will introduce distortion. Furthermore, unless the silver coating on the mirror is very perfect there will be a large amount of light loss. For ordinary "star-gazing" purposes the comfort of the observer makes the instrument a very popular one. (W.K.G.)

COUGAR. Mammalia, Carnivora. Large North American **cats** of several species. The Florida cougar, *Felis coryi,* lives in wild lands of central Florida, another species in Louisiana, and the western species, *F. oregonensis,* is still found from the Rocky Mountains to the coast. The species once found throughout the eastern half of the continent, *F. concolor,* is now limited to the wild mountainous areas of the east or is entirely extinct. The western species is called the mountain lion or puma and the eastern species was also called panther, painter and catamount. (A.W.L.)

COULOMB. The coulomb is the practical unit of quantity of electricity. It is primarily an electromagnetic unit, the absolute coulomb being $\frac{1}{10}$ of the abcoulomb or **abampere**-second. The "international coulomb," however, is defined electrochemically, as the quantity of electricity transferred during the electrolytic deposition of 0.001118 gram of silver from a silver nitrate solution in a **coulombmeter.** It is thus the basis of the international **ampere.** The international coulomb is about 0.99995 of the absolute coulomb.

The coulomb, while convenient in reference to electric currents and electrochemical processes, is far too large for electrostatic purposes, being approximately equal to 3×10^9 e.s.u. of electricity. If one could perform the impossible feat of charging two small spheres with one coulomb each, these charges, if placed one meter apart, would attract or repel each other with a force of about 9×10^{14} dynes or well over a million tons, and the potentials in the near vicinity of the charges would reach hundreds of billions of volts. (L.D.W.)

COULOMBMETER or COULOMETER. An electrolytic cell used for the measurement of the quantity of electricity passing through a circuit; also called "voltameter." A standard form, based upon the definition of the international **coulomb,** and depositing silver, has been developed at the Bureau of Standards. (*Bulletin Bureau of Standards,* 13, 479, 1916.) The more practical form for laboratory use employs copper electrodes in a bath of copper sulfate. The thin copper cathode, between two heavy copper anodes, is removable for weighing; and since one coulomb deposits 0.000329 gram of copper, the weight of the copper deposit enables one to determine the quantity of electricity in coulombs. A solution recommended for this cell consists of 15 grams of crystalline copper sulfate, 5 grams of pure sulfuric acid, and 5 grams of pure alcohol, dissolved in 100 grams of distilled water. (L.D.W.)

COULOMB'S LAWS. This term usually refers to the familiar laws of interaction between two concentrated electric charges and between two magnetic poles. The force of attraction or repulsion between two charges (or poles) is directly proportional to the product of the charges (or pole strengths) and inversely to the square of the distance between them. The similarity to the Newtonian law of **gravitation** will be readily noted.

The experimental proof of these laws was carried out by means of the **torsion balance,** employing small, electrified balls or the poles of slender bar magnets. In the electrical case, a far more precise proof of the inverse-square feature is based on the mathematical analysis of the experimental fact that at every point within a charged, hollow, spherical conductor, the electric field intensity due to the surface charge is exactly zero. (See **Friction.**) (L.D.W.)

COUMARIN. Bean.

COUMARONE. Furane and Related Compounds.

COUNTERBALANCING. Counterbalancing means simply the application of extra **mass** to a system in order to produce balance for the system as a whole, and to offset the unbalance arising from some particular part. Rotating machinery, especially high-speed machinery, needs to be counterbalanced if the center of gravity of the rotating mass does not lie on the axis of rotation. Hoists are frequently counterbalanced so that a descending weight will supply some of the energy required for hoisting the non-useful load. Numerous examples of counterbalancing will be found in everyday practice, but those cases associated with the counterbalancing of high-speed rotating machinery are the most imperative of solution. (See **Balance.**) (F.T.M.)

COUNTERBORE. Counterboring, spot-facing, countersinking, and center drilling are hole-enlarging operations generally performed on a drill press, although they are actually reaming operations. Counterbored holes are those with cylindrical enlargements, for fillister head screws; spot-faced holes are counterbored to a depth just sufficient to clean up the surface. Countersunk holes have conical enlargements; center drilling is essentially countersinking, using an integral drill and countersink for machining center holes for turning operations on lathes.

Both counterboring and countersinking are performed with piloted cutters, but usually (except for center drilling) require separate operations for drilling the body hole before countersinking or counterboring. A subland drill is a twist drill of special design, constructed so as to provide separate cutting edges and flutes for each hole diameter, so that counterbored holes may be produced in one operation. (H.C.H.)

COUNTERPOISE. This is a network of wires placed near the ground to serve as the ground side of the circuit of a radio radiating system, the other side being the **antenna.** It is used primarily where the actual **ground** has such poor conductivity that satisfactory operation without it cannot be obtained. This network should extend well beyond the antenna if it is to be fully effective. (L.R.Q.)

COUNTERSHAFT. Shaft.

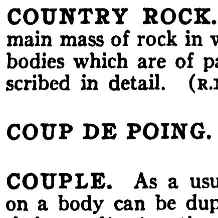
COUNTERSINK. Counterbore.

COUNTING TUBE. A type of **ionization chamber** adapted to detect the arrival of individual ionizing particles, such as **beta rays** or **cosmic-ray** particles. The enclosure is commonly cylindrical with its thin metal wall serving as one electrode, preferably surrounded by a protecting envelope of glass. The other electrode may be a needle-point projecting into the cylinder, as in the Geiger counter, or a fine, straight, axial wire, as in the Rutherford-Geiger and the Geiger-Müller counters. These electrodes are maintained at a potential difference just too small to ionize the air between them without some additional assistance. When an ionizing particle enters through the tube wall, the resulting ionization causes a momentary current. This may be amplified to operate a suitable signal or even to record itself on a drum or tape. (L.D.W.)

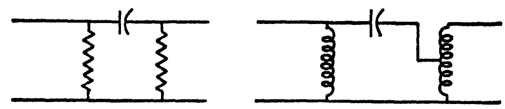
COUNTRY ROCK. The general term used for the main mass of rock in which occur the **veins, dikes** or ore bodies which are of particular interest, or which are described in detail. (R.M.F.)

COUP DE POING. Paleontology of Man.

COUPLE. As a usual thing the action of two forces on a body can be duplicated by a single force, equal to their **resultant,** acting at their **center of pressure.** Two parallel forces of equal magnitude but opposite direction cannot be reduced to a single force. They form a couple. The effect of a couple upon a body is independent of the location of that couple with respect to the body. The net action of several couples all in the same plane on a body is equal to the algebraic sum of the moments of the couples, the sign being determined from the direction of rotation which the couple tends to give. The moment of a couple is the product of the perpendicular distance between the forces and one of the forces. The action of any force, acting at any particular point on a body, upon another point lying in the plane of the force can be resolved into another force of the same magnitude acting at the desired point plus a couple. For example, let F be any force acting at point a, and b any other point at distance d from the line of action of F. At point b place two equal and opposite forces F and F' which are parallel to the direction of the original force F. Then F' at b and F at a form a couple Fd, leaving F which acts through point b. The effect on point b of the latter force and the couple is the same as the effect of the original force F acting at a. Thus it is seen that it is possible to replace a force acting at a with an equal force acting at b, and the couple Fd, where d is perpendicular distance from b to the force F in its original position. (F.T.M.)



COUPLED CIRCUIT. While any group of circuits which are so connected or related that effects in one produce effects in the other constitute a coupled circuit, the term is usually used to designate circuits related so a-c effects are transferred but steady state d-c effects are not. The two most common classifications of coupled circuits are the inductive and the capacitive coupled circuits, so named because of the primary method of transferring the effects. Capacitance coupling is used quite extensively in various vacuum tube amplifier circuits, in thyratron circuits, and similar applications where it is desired to block d-c effects and transfer a.c. Since the **condenser** does this it may be used as the common element between the two circuits. The so-called resistance coupled amplifier is really capacitance coupled. Fig. 1 shows examples of this type. Inductive coupling is the most widely used type since it is used extensively in the power field as well as in the communications and electronics fields. The ordinary power **transformer** is the



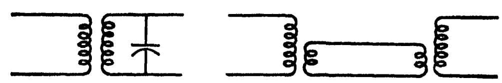


Fig. 1. Capacitance-coupled circuits (top).
Fig. 2. Inductance-coupled circuits.

means of inductively coupling two power circuits. The various transformers, tuning coils, etc., of radio circuits are other examples. Fig. 2 shows some typical circuits.

For two circuits to be inductively coupled an inductance element in one circuit must be so related to an inductance in the other that flux set up by one links the other. Thus a current flowing in circuit number 1 produces a flux which, in part at least, links the other. When this flux changes it produces a voltage in the second coil, and if the second circuit is closed a current flows. This flux which links both circuits is the mutual flux and the effect gives rise to **mutual inductance.** Mutual inductance may be defined as the flux linkages in one circuit per ampere in the other,

$$M = N_2\phi_m/I_1$$

where M is the mutual inductance, $N_2\phi_m$ the flux linkages by the mutual flux in circuit 2 and I_1 is the current in circuit 1 which caused the flux ϕ_m. M is also expressible in terms of the self-**inductance** of the coupled coils,

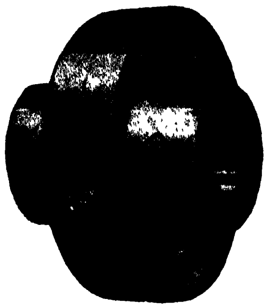
$$M = k\sqrt{L_1L_2}$$

where k is the coefficient of coupling and the L's are the respective self-inductances. The manner in which the current in the secondary circuit varies is a rather complicated function of the various circuit parameters, frequency, and primary current. However, there is a certain value of coupling which will produce a maximum secondary current for fixed values of the other parameters. This value of coupling is called the critical coupling. In the usual inductive coupled circuit used at radio frequencies where the circuits are tuned, the secondary current plotted as a function of frequency presents a single peak, increasing in value, up to the critical coupling, then presents a double peak with no increase in value as the coupling is made still closer.

Not only are coupled circuits used to transfer a-c energy from one circuit to another, but by proper design may be made to match the impedances of the connected circuits also. (See **Impedance Matching.**) (L.R.Q.)

COUPLING. A means for joining two parts. There are a number of specific uses of the term. A pipe coupling is a hollow cylinder with internal pipe threads, used to join two sections of externally threaded pipe, either of the same or of different sizes; in the latter case, the unit is referred to as a reducing coupling. Shaft couplings are used to connect rotating shafts, and are of two types—rigid and flexible. The sleeve coupling is an example of the former type, and consists of a hollow cylinder, usually provided with a keyway and set screws to prevent relative rotary and axial motion of the shafts. Another type of rigid coupling, the flange coupling, consists of a disk and hub, on each shaft, connected by

through bolts. Since perfect alignment of two theoretically collinear shafts is difficult to attain, some form of flexible coupling is usually employed for moderate



Flange coupling.

or heavy duty transmissions, such as motor-generator sets, motor-driven pumps, and the like, to prevent the transmission of shock and eliminate stress reversals. There are numerous commercial forms of flexible couplings; one type is similar to a flanged coupling, but employs laminated steel pins instead of through bolts for transmitting power from one flange to the other. In another form, two sprockets of equal size are mounted—one on each shaft—and connected by means of a roller or silent **chain**. In other forms, the connection between the shaft flanges is effected by springs or by bolts or pins mounted in rubber.

For connecting shafts whose axes are slightly out of alignment, but approximately parallel, the Oldhams or cross-keyed coupling is used. This device consists of two coupling halves fastened to the shafts; each half has a groove or slot cut in it, and the two halves are arranged so that the grooves are perpendicular. The halves are connected by a central member with perpendicular tongues that engage the coupling half slots. In some instances, cross-keyed couplings are used as flexible couplings; in such cases, the central member is made of fiber or has leather-faced contact surfaces.

A universal joint is a rigid coupling for connecting shafts whose axes will intersect if prolonged, and for applications where the angle between the shaft axes may vary during operation. The device is usually composed of two forked coupling halves, with a central block free to oscillate about two mutually perpendicular axes lying in a plane perpendicular to the shaft axes. Universal joints operate satisfactorily when the shaft coincidence error does not exceed ten to fifteen degrees; beyond this range, the joint is likely to be quite inefficient. (H.C.H.)

COURLAN. Aves, Gruiformes. A large Brazilian bird (**Aves**) which resembles the rails in appearance and habits. Also called the limpkin. (A.W.L.)

COURSE. The term course is used in a number of contradictory meanings by different writers on the general subject of **navigation.** During the past few years the U. S. Navy has adopted two standard meanings for this term. Course is the **direction** that a navigator desires his ship to follow for a given period of time, and course is also the direction that a navigator hopes his ship has followed for a given period. To be more specific: In the first place, the navigator knows or assumes that his ship is in a given location at a given time and he wishes to proceed to another specified location. By graphical methods, on a **chart** or **small-area plotting sheet,** or by any one of a number of standard computational methods, such as **plane sailing, middle-latitude sailing, Mercator sailing, great-circle sailing, composite sailng,** etc., the navigator obtains the direction and length of the line joining the two points. These are known as the predicted course and distance between the two locations. In the second place, the navigator knows, or assumes, that his ship is at a given location at a certain time. With the ship proceeding on a given **heading** with a known speed, the navigator may determine, by graphical or computational **dead-reckoning** methods, a position of the ship at the end of a definite period of time. The direction and length of the line joining the two locations are the assumed course and distance between the two points, or the dead-reckoning course and distance made good. (See **Track.**) (W.K.G.)

COURSER. Aves, Charadriiformes. Long-legged birds (**Aves**) related to the plovers, found in Africa and southern Europe. One species is a desert bird. (A.W.L.)

COURTSHIP. The special behavior of animals in seeking mates.

Courtship varies from the complex behavior of birds and mammals to the random association of the sexes in many simpler animals, where meeting under proper conditions inevitably results in mating without evident preliminaries.

In its more complex aspects courtship almost invariably consists of some display on the part of the male which influences the female to accept or reject his advances, and is often accompanied by rivalry between males which may be settled by combat. The singing of male birds during the breeding season and the display of brilliant plumage by some species are well-known examples, and unusual evolutions in flight are little less familiar. Such behavior also occurs among the invertebrates, particularly among the spiders and some of the insects. Some of the South American birds, the **tinamous,** reverse the usual type of courtship. In these species the females court the males. (A.W.L.)

COVALENCE. **Valence.**

COVARIANCE. The covariance is defined as $\Sigma(x_i - \overline{X})(y_i - \overline{Y})N$. It equals $r\sigma_x\sigma_y$, where $\overline{X}$ is the **mean** of the x's, $\overline{Y}$ = mean of the y's, r is the **coefficient of correlation,** σ_x and σ_y are the **standard deviations** of x and of y, respectively. (L.A.A.)

COVELLITE. The mineral covellite, **cupric sulfide,** CuS, is **hexagonal,** usually in thin platey crystals, but may be massive. It has a hardness of 1.5–2; specific gravity, 4.6; luster, submetallic to resinous; color, dark indigo blue, sometimes showing a purplish tarnish, or if moistened may appear purple in color. Its streak is dark gray to black; it is opaque. Covellite is found associated with **chalcopyrite, bornite, cholcocite,** etc., and is believed to be chiefly of secondary origin. Covellite occurs in Serbia, Saxony, Sardinia, Argentina, Chile, Bolivia and Peru, and in the United States at Butte, Montana, and in Colorado, Wyoming and Utah. This mineral was named for Covelli, who discovered it in the lavas of Mt. Vesuvius. (E.S.C.S.)

COWBIRD. Aves, Passeriformes. 1. The yellow **wagtail** of England. 2. A dark-colored bird, *Molothrus ater,* of southern Canada and the United States, related to the blackbirds, and several species of the same genus extending from Texas into South America. Most of these species deposit their eggs in the nests of other birds like the European cuckoo. They are named from their frequent association with cattle and before the settlement of North America the common species was called the buffalo bird. (A.W.L.)

COWLING. **Cooling, Engine.**

COWLING, ENGINE. Cowling is removable covering placed over or around an engine. Its purpose may be simply that of a weather guard—or it may serve the more complex function of streamlining or engine cool-

ing. The *hood* of an automobile engine is a simple form of cowling.

It is in connection with air-cooled airplane engines that cowling is of the greatest technical interest since there it becomes part of high-performance design. Any inferiority of cowling design will severely penalize airplane performance.

At first, radial air-cooled engines were installed without cowling of any description; later the crankcase and accessory sections were enclosed in a streamlined aluminum cowling, leaving cylinder barrels and heads exposed. Then it was found that a narrow ring (Townend ring) around the cylinder heads increased speed by confining turbulence. However, the ring cowl tended to produce high cylinder-head temperatures in engines of high specific output. During the decade from 1930 to 1940 the whole subject of cowling and cooling of airplane engines was investigated in considerable detail by private and governmental organizations, with the result that much better cooling is obtainable with far less aerodynamic drag than was possible before. Most of this progress lay in the field of scientific cowling design. While most of this work was directed toward the radial air-cooled engine, reduction of the drag of liquid-cooled engines was also studied, especially that originating in the coolant radiator and the air ducts and scoops associated with it.

It was shown by F. W. Meredith that if air is admitted at high speed to a diffuser passage, then heated and expanded through an efficient nozzle, a jet thrust is produced which has capabilities of offsetting the drags of the system. Liquid-cooled engine advocates were quick to see the advantages of improved design of cooling air ducts and were able to produce airplanes with extremely low cooling-system drags. Later, in the radial engine field, improved designs of cowling were able to accomplish almost the same effect.

In the United States the NACA undertook comprehensive investigation of cowling and cooling of large radial engines. The NACA cowl is a close-fitting covering, usually cylindrical, placed around the engine and extended as a skirt some distance rearward of the cylinders. Its nose section is designed to divide the air flow into a small portion which enters the cowl, and a much larger portion which flows smoothly over the outside surface. Equally important is the inner cowling, or cylinder baffling, which prevents wastage of cooling air. The cowling skirt ends in a slot between the cowl and fuselage or nacelle. The heated air from the engine leaves through this slot and mingles with the main air flow outside the cowl.

Diagrams of the inner engine cowling (baffles) are shown for different types of air-cooled engines. These

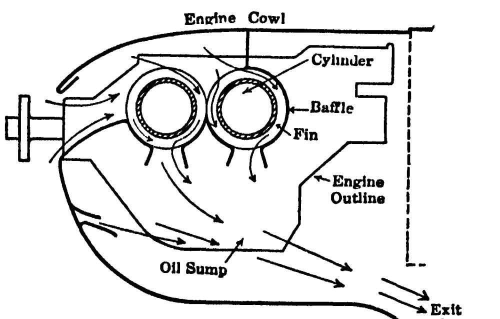


Fig. 1. Cowling and pressure baffles for horizontally opposed engine.

baffles confine the air flow to the region of the cooling fins, thereby using the minimum air for the necessary cooling. A pressure differential ΔP exists across these baffles because of the impact pressure existing upstream and the low pressure of the exit slot. Expressed as a percentage of the **dynamic pressure** corresponding to airplane speed, this ΔP may be 60–80%. It can be controlled by making the exit slot variable, as with

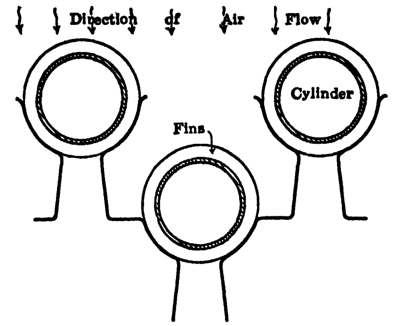

Fig. 2. Development of pressure baffle arrangement for two-row radial engine.

cowl flaps or sliding skirt. A fixed exit slot of sufficient size to cool a large engine at low speed promotes unnecessarily high cooling-system drags at higher speeds. This effect is not as noticeable for small engines.

Propellers are expected to provide an air inflow to the cooling system when the airplane is on the ground.

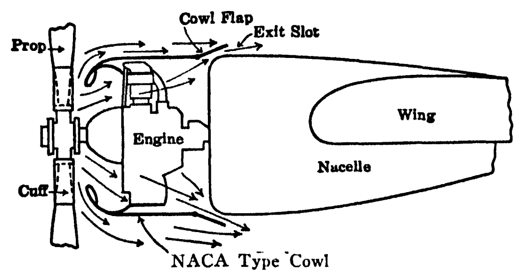

Fig. 3. Cooling air flow in NACA cowl.

The shanks of large metal propellers have evolved into nearly cylindrical sections possessing but little fan action. To provide cooling air for idling, cuffs of airfoil section are fitted to the propeller blade shanks. Engine-driven axial blower fans have been used for the same purpose.

Improvements continue to be made in the cooling and cowling of aircraft engines. Ample opportunity for improvement still exists since the engine delivers to the cooling system more energy than it does to the propeller. In time it may be possible to make much of this energy available as reaction propulsion. (F.T.M.)

COWPER'S GLAND. A gland of the male reproductive ducts of mammals whose secretion is part of the seminal fluid (see **Reproduction**). (A.W.L.)

COWRY. Mollusca, Gasteropoda. Compactly oval shells with a long narrow aperture, smooth surface, and often bright colors.

There are many species of cowries, especially in the Pacific and Indian Oceans. The shells of some are used as money and for decorations. (A.W.L.)

COXA. The segment by which the leg of an **arthropod** is joined to the body. (A.W.L.)

COXAL GLAND. Excretory glands opening on the fifth segment of the body in the **king crab** and **scorpions**. **Coelomoducts**. (A.W.L.)

COXOPODITE. **Biramous Appendage.**

COYOTE. Mammalia, Carnivora. **Wolves** of several smaller North American species, ranging from Iowa to

California and from Mexico into Canada. The common coyote or prairie wolf, *Canis latians,* occurs in the northern prairie area, the plains coyote, *C. nebracensis,* throughout the great plains, and the mountain coyote, *C. lestes,* in the western mountain areas.

Coyotes sometimes destroy chickens and other small domestic animals. They have been relentlessly killed for their depredations and remain common only in sparsely settled regions. (A.W.L.)

COYPU. Mammalia, Rodentia. A large aquatic **rodent** of South America whose habits are like those of the muskrat. Its fur is the nutria of commerce. (A.W.L.)

CRAB. Crustacea, Decapoda. **Crustaceans** with a short broad **cephalothorax** and a small abdomen bent below it. The large pinchers and four pairs of legs are

Above, male spider crab. Left, female spider crab. Right, ghost crab. Center, mud crab. *(From Mayer, Seashore Life, N. Y. Zool. Soc.)*

the only conspicuous appendages. Most species of crabs are found in or near the ocean but some are terrestrial and others live in fresh water. The land crabs deposit their eggs in the water. The many species of crabs constitute a division of the order named the Brachyura from the short abdomen.

A number of species of crabs are used for food. Of these the edible crab of the Atlantic, which ranges from Cape Cod to Louisiana, and the edible crab of the Pacific Coast, are the most important species.

Many crabs have received common names which apply to one species or to a group of similar species. Among these names are spider crab, hermit crab, fiddler crab and land crab. (A.W.L.)

CRACKING PROCESS. Gasoline, as one of the products of crude oil, is required today in such quantities for motor vehicles that were the crude oil to be separated into its commercial components (such as petroleum ether, gasoline, kerosene, etc.) by **distillation** or **fractionation** through heating and condensation, there would be an uneconomic excess of the products other than gasoline. For petroleum, the natural crude oil, is made up of a complex mixture of **hydrocarbons,** which differ in composition and structure. When petroleum is distilled, the more volatile fractions, such as gasoline, are found to be composed, in general, of hydrocarbons of simpler molecular structure—that is, those having molecules which contain a comparatively small number of atoms. Speaking broadly, the hydrocarbon molecules having larger numbers of atoms are more largely concentrated in the less volatile petroleum products. In the cracking process these larger molecules are broken up to produce, in part, a greater yield of gasoline and other low-boiling fractions. One of the simplest methods of cracking is by heating under pressure. By efficient cracking, gasoline yields of 60% or more have been obtained from certain crudes. (For further discussion of cracking, see **Hydrocarbons; Gasoline.**) (F.T.M.)

CRAG IMPLEMENTS. **Paleontology of Man.**

CRAIT. Reptilia, Sauria. A poisonous **snake** of India, *Bungarus caeruleus,* related to the cobras and adders. It is said to conceal itself in houses, and to this fact must be attributed its record of killing more human beings than any other snake, with the exception of the cobra.

The name crait has also been applied to several related species of Oriental snakes, including the banded adder. (A.W.L.)

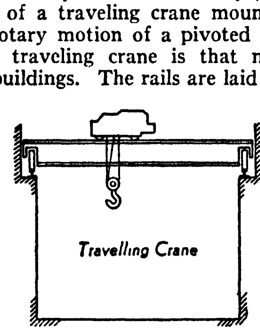
CRANBERRY. **Heath Family.**

CRANE. Aves, Gruiformes. Large birds (**Aves**) with long legs and neck. They are superficially like the larger herons and the name crane is sometimes inaccurately applied to the latter birds, especially to the great blue heron. Cranes are found in Europe, Asia, North America and Africa. (See **Lifting Crane.**) (A.W.L.)

CRANE FLY. Insecta, Diptera. **Insects** which resemble mosquitoes in form but are usually much larger. They have a V-shaped groove across the thorax and have no scales on the wings.

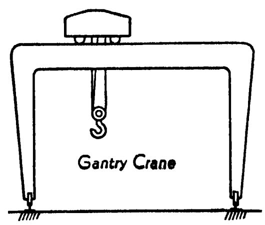
The **larvae** of some species live in the ground and are sometimes injurious to the roots of grasses and grains. These larvae are called meadow maggots or leather jackets. They come to the surface at times and can be destroyed by the use of poison baits. (A.W.L.)

CRANE, LIFTING. In engineering, a crane is a hoisting machine in a particular category. It is not a simple matter to point an exact distinction between **hoists** and cranes, as they have not been clearly distinguished in common usage. However, cranes might be classified as those types of hoisting machines where vertical lift is not the primary purpose (as it is, for example, in the case of an elevator) but where the lift is only that sufficient to allow proper clearances for those parts being transported by the crane. The primary purpose of a crane is to lift a piece from one place and set it down in another, and so a degree of horizontal freedom is essential. The horizontal movement may be accomplished in two ways, viz., the rectilinear motion of a traveling crane mounted on parallel rails, or the rotary motion of a pivoted swinging crane. The ordinary traveling crane is that most frequently found inside buildings. The rails are laid on the walls or



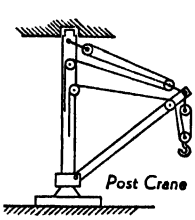
on a special steel framework inside the walls. Rolling on the rails on each side is a wheeled carriage which carries the end of a **girder** bridging the distance between the rails. This girder must be sufficiently strong to support by beam action the lifting capacity of the crane. A rolling carriage containing the hoist is mounted on top of the girder so that it gives motion in a direction perpendicular to the main rails. Thus every part of a

rectangular floor area inside the walls may be reached by the crane. This type of crane is widely used in factories and other plants where heavy objects must be transported about in a rectangular area. If the crane is seldom used, it may be a hand-operated type, having chains reaching down to the floor level to be pulled by hand—one to roll the crane back and forth along the main rails, the other to pull the carriage from side to side and to operate the hoist. Electrically operated traveling cranes usually have two motors, one to roll the crane along the main supports, the other to move the carriage on the crane girder and operate the hoist. The control can be accomplished remotely from an electrical control panel, or by an operator stationed on a cab which travels with the crane. The latter is generally the case when the crane is in almost continuous use. In outdoor locations, where it is not convenient to erect a structure to carry the overhead rails, the crane can be equipped with legs which support it on rails at the ground level. It is then a Gantry crane.



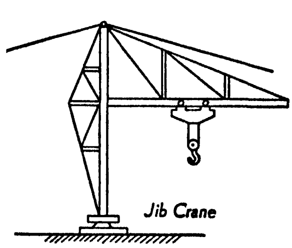
Gantry Crane

The post crane is a simple type of rotary crane frequently used for unloading material from one transportation system and placing it on another. The area which can be served by a crane of this type is more limited than in the case of the traveling crane, but it is a simpler, cheaper type. As shown in the figure, the post is supported on pivots at the top and bottom. It would be necessary to support the top by guy wires out of doors. The principal members are the post and the **boom**. In the type shown, the radius of the circle in which the hook travels can be varied, but this is fixed in some post cranes, where the post and boom are connected by a simple tie **rod** member. If the lower pivot of a post crane were made large and heavy, the top support could be eliminated. The load would be carried by bending in the post, which would then be shortened and become the pillar of a pillar-type crane.



Post Crane

The jib crane is better adapted for an all-steel rotary crane where the radius to be covered is larger than that to which the post or derrick type crane is suited. The radius is varied by changing the position of the trolley on the jib beam. The post and jib cranes may be swung about either by hand or by motors. Cranes having a further degree of mobility are the locomotive and crawler types, which are self-contained units mounted, in the case of a locomotive crane, on a railway carriage, or in the case of the crawler crane, on caterpillar treads. They are motivated by internal combustion or steam engines, and in structure are somewhat similar to a pillar crane. (F.T.M.)



Jib Crane

CRANIATA. **Vertebrata.**

CRANIUM. **Skeletal System.**

CRANK. **Crankshaft, Bell Crank.**

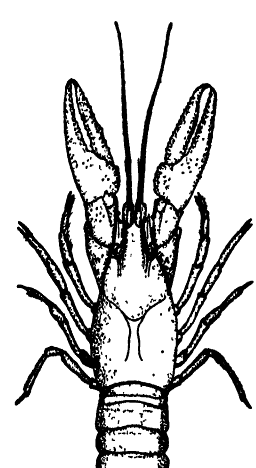
CRANKSHAFT. A crank is a bent arm which moves with rotary motion about its unbent end. In order to provide a support for this rotation the crank is mounted on a crankshaft. The crank and crankshaft form one of the important basic units of mechanism. There has been found no simpler, more efficient way of transforming rotary to reciprocating motion, or vice versa. The crank alone does not accomplish this, but in conjunction with the **connecting rod** and slider, it forms the basis of many such important machines as engines, pumps, compressors, and a host of other mechanisms. A simple crankshaft of the overhung type is readily made from an arm (or disk) and a crank pin which is set into it at some radial distance from a crankshaft, which is the center of rotation. This type is widely used where a crankshaft is to accommodate but one crank, and where the crankshaft bearing surface is entirely on one side of the crank. Multiple cranks on the same crankshaft are obtained by fitting the crank pin between two crank arms, so that the connecting rod may swing freely without interference with the crankshaft. Multiple throw crankshafts are made by building up the crank pin between two cranks, and by machining from a single forged piece. It is the function of a crank to transmit the force at the crank pin into a torque at the crankshaft, the torque being equal to the component of crank pin pressure perpendicular to the crank radius multiplied by that radius. Since crank pin pressure is not always exactly perpendicular to crank radius, it follows that a crank may carry some compression or tension as well. It should never be loaded with bending by forces parallel to the crankshaft. (F.T.M.)

CRASPEDON. **Velum.**

CRASPEDOTE. Provided with a craspedon or **velum.** Applied to the medusae of many species of **Hydrozoa** in contrast with the jellyfishes. (A.W.L.)

CRAYFISH. Crustacea, Decapoda. Fresh-water **crustaceans** resembling small lobsters, with which they are closely related. They are widely distributed. The term is applied to a limited extent to certain marine species which are more closely allied to the lobsters than to the true crayfishes. In the United States **Cambarus** is a common genus East of the Rockies, and *Astacus* to the west.

Crayfishes are eaten in Europe and to a limited extent in the United States. (A.W.L.)



Crayfish.

CREAM OF TARTAR. **Tartaric Acid.**

CREEP. Creep of metals is slow plastic deformation under stress. When lead is subjected to any considerable stress, deformation occurs and continues indefinitely or until rupture takes place. On the other hand, steel and most structural metals do not creep or flow plastically until the stress level is above

a critical point such as the **yield point** in mild steel. At elevated temperatures, e.g., 900° F., creep occurs at much lower stresses and must be carefully considered in the design of equipment such as boilers and tubes which are intended to operate at elevated temperatures over long periods of time. Alloy steels have been developed having higher creep strengths than carbon steels.

Creep strength is the unit stress which will produce deformation at a specified rate at a specified temperature; for example, the creep strength of a certain 0.15% carbon open-hearth steel at 1000° F. is 6100 lbs. per sq. in. for a rate of 0.01% elongation in 1000 hours. Other values for this material are 6900 lbs. per sq. in. for a rate of 0.1%, and 7800 lbs. per sq. in. for a rate of 1.0% elongation in 1000 hours. Creep strength values can only be determined by long-time laboratory tests under carefully controlled conditions of temperature and loading.

The term is used by geologists to designate the slow movement of soil and rock waste down a slope. This movement is due to the combined influence of gravity, frost, and **ground water**. Creep has been proved to be an important factor in soil erosion even on relatively flat slopes. (R.H.H., R.M.F.)

CREEPER. Aves, Passeriformes. Small insectivorous birds (**Aves**) which cling to the trunks of trees or cliffs in seeking food. They are found in the Northern Hemisphere and are represented in North America by the brown creeper, *Certhia familiaris.* (A.W.L.)

CREODONT. **Fossil Mammals.**

CREOSOTEBUSH. *Larrea tridentata.* Zygophyllaceae. An evergreen shrub, sometimes growing to a height of 12′ but usually smaller, which is a prominent species of large parts of the semi-desert regions of California, Arizona, New Mexico, western Texas, and northern Mexico. In parts of its range the plant may occupy large areas as a practically pure stand. Creosotebush bears small yellow flowers and has a characteristic odor of creosote. (B.S.M.)

CREPUSCULAR. Active during twilight.

CREST GATE. The principal items of equipment to be used in conjunction with a dam, for the maintenance of desired water conditions, are crest gates, sluices, and spillways, and sometimes, by legal requirement, by-passes for fish or for logs. In order to control the head closely, crest gates are provided on the spillway sections, but where the spillway is a natural rock channel at one end of the dam it is convenient to effect the control by sluice gates. The different types of crest gates in use are summarized as follows:

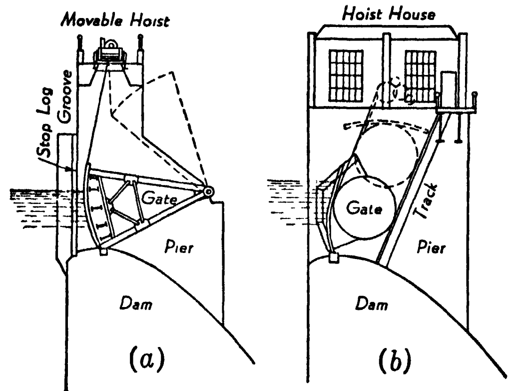
1. Sliding gates.
2. Tilting gates.
3. Rolling gates.
4. Taintor gates.
5. Stationary flash boards.

Sliding gates are limited in capacity by the effort that is required to move them against frictional drag set up by heavy water pressure. When equipped with roller guides, as in the Stoney roller gate, the capacity per gate is much increased.

Tilting gates usually are so constructed that a predetermined rise of water against them automatically tilts them to the open position, then, after the water has fallen to its normal elevation, they automatically return to the closed position.

Rolling gates are supported on a cylindrical drum which can be rolled up a steep incline by various means. Chains, wrapped around the cylinder ends, are connected to hoists which roll the gates up an incline of 20° to the vertical.

The Taintor gate has been widely used in this country for crest control. The face of the Taintor gate is the circumference of an arc the center of which is at the pivot point. This causes the resultant of water pressure against the gate always to pass through the pivot so

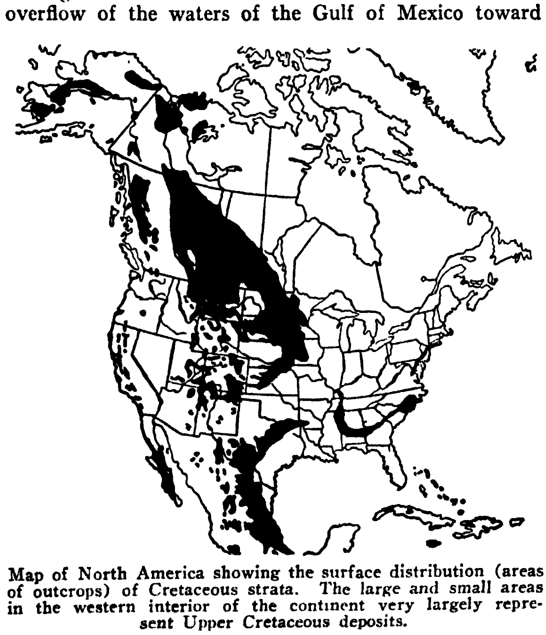


Crest gate. (*a*) Taintor. (*b*) Rolling.

that, with the exception of pivot friction, it is necessary to handle only the weight of the gate itself when opening or closing it.

When no other control is exercised, it is good practice to use temporary flash boards on the spillway crest. Generally these are constructed of wood and held in place by iron pins which will bend over and release the flash boards should the water rise to a point where the maximum spillway capacity is needed to pass the flood. (F.T.M.)

CRETACEOUS PERIOD. The last major division in the **Mesozoic Era** of the geologic time-scale. Type locality, chalk (creta) cliffs of the English Channel. The period was named by A. d'Halloy in 1822. In 1877, Hill proposed that the Lower Cretaceous be erected as a separate system which he called the Comanchean. The Comanchean period began about 135 million years ago and lasted about 25 million years. The Cretaceous period began about 110 million years ago, and lasted about 50 million years. The greatest thicknesses of Cretaceous strata in the United States occur in the Rocky Mountain region and in California. During the Cretaceous Period there was also an extensive overflow of the waters of the Gulf of Mexico toward



Map of North America showing the surface distribution (areas of outcrops) of Cretaceous strata. The large and small areas in the western interior of the continent very largely represent Upper Cretaceous deposits.

the southern interior of the United States, depositing there a great series of overlapping sediments. This is the type region of the Lower Cretaceous or Comanchean. While the Atlantic and Gulf continental margins were invaded by the Cretaceous Sea, the region of the **Appalachian geosyncline** had been reduced to a **peneplain** which may have been overlapped by marine sediments. In the Great Plains region were deposited fresh-water shales and sandstones with local swampy areas in which were formed numerous **lignites,** subsequently altered to bituminous coal. The Middle Cretaceous saw a great marine invasion of western North America from the Gulf of Mexico to the Arctic Ocean. Deposits of Cretaceous Age are well represented in central and western Europe, with fairly continuous marine deposition throughout the entire period. Cretaceous deposits occur in South America, especially in Brazil. As further evidence that there was widespread invasion of the continents by oceanic waters during this period, marine sediments occur in southwestern Asia, China, Himalayas, Japan, Siberia, and Africa. Important mineral resources are of Cretaceous Age. In the United States the Cretaceous formations contain numerous important aquifers which underlie great semi-arid areas. Bituminous coal beds of average value occur in Alaska, Australia, British Columbia and Germany. Important oil pools occur in the Gulf region. The Cretaceous clays of the eastern United States are extensively used in the manufacture of china and building materials. The famous sulfide copper ores of Butte, Montana, occur in igneous rocks of Cretaceous and Early Tertiary age. Lower Cretaceous plants and animals were only slightly different from those of Jurassic time. Ferns, **cycads, ginkgoales** and conifers still predominated, and the principal marine invertebrates were **ammonites** and **belemnites.** During the Cretaceous there was a great expansion of the **pelecypods, gastropods,** and the modern types of fishes. The Mesozoic reptiles had reached their climax in the early Cretaceous and, except for a few large and bizarre forms, were on their way to extinction. The most remarkable types were **Triceratops** (horned dinosaur), **Tyrannosaurus** (tyrant dinosaur), **Tylosaurus** (marine lizard), and **Pteranodon** (crested pterodactyl, or flying reptile). Since uppermost marine Cretaceous does not occur in North America, there appears to have been a pronounced period of uplift and erosion, accompanied by mountain building, with the combined growth of the Cordilleran ranges. This period of diastrophism, which closed the Mesozoic Era in the western hemisphere, is called the **Laramide Revolution.** (R.M.F.)

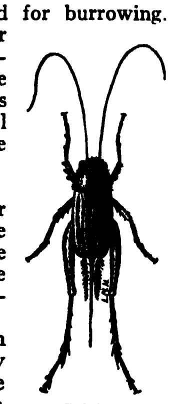
CRETINISM. **Thyroid Gland.**

CREVASSE. 1. A crack or open fissure in a glacier. 2. A break in the levee of an old-age, meandering stream, often leading to disastrous floods, as in the case of the lower stretches of the Mississippi River. (R.M.F.)

CRIBELLUM. A perforated plate associated with the spinnerets of some spiders. Through it a peculiar form of silk is produced with the aid of the **calamistrum.** (A.W.L.)

CRIBIFORM ORGANS. Series of thin vertical calcareous plates found in the arms of some starfishes (**Asteroidea**). (A.W.L.)

CRICKET. Insecta, Orthoptera. **Insects** related to the katydids and grasshoppers and, like some of these forms, well known for their resonant singing. The true crickets constitute a family (Gryllidae) which contains the common or field crickets and in addition several other forms more or less different in appearance. The field crickets are black or brown species, some of which enter houses. Tree crickets are usually green with broad transparent wings. They frequent trees and shrubs. Mole crickets are thick-bodied brown insects whose forelegs are strongly developed for burrowing. In addition to these and a few other forms of crickets several insects belonging with the katydids among the long-horned grasshoppers bear this name. They are the cave or camel crickets, the sand cricket, and the Mormon cricket. (A.W.L.)



Cricket.

CRINOIDEA. The sea lilies, feather stars, and basket stars, a class of the phylum **Echinodermata.** There are now only a few hundred species of these animals although several thousand fossil species are known.

The crinoids are distinguished from the starfishes and other echinoderms by the following characteristics: 1. The body consists of a disk, arms, and a stalk. 2. The mouth and anus are both directed upward. 3. The arms bear small lateral branches and in many species fork repeatedly.

Most of the living species lose the stalk when mature and become free-swimming. These forms, known as comatulids, are found in shallower waters of the ocean, where they swim or creep by means of the arms. The stalked species are found in deep water.

The classification of crinoids is of little interest save to specialists. Many families are recognized and they are sometimes grouped in three orders: Holopodida, Ptilocrinida, and Comatulida. The first includes a primitive attached form, the second the stalked crinoids, and the last the free species. (A.W.L.)

CRISIS. 1. The turning-point of a disease, either toward recovery or death. In certain diseases this may occur dramatically—particularly in **pneumonia,** where the high fever suddenly drops, and the acutely ill, delirious patient within a short time becomes quiet, of better color, breathes more easily, and seems to be definitely on the way to recovery. 2. A painful paroxysm or seizure seen in **syphilis** of the spinal cord (tabes dorsalis) where it usually occurs as a "gastric crisis" characterized by severe, intractable abdominal pain. (D.M.H.)

CRISTOBALITE. **Tridymite.**

CRITICAL ANGLE. **Total Reflection.**

CRITICAL COUPLING. **Coupled Circuits.**

CRITICAL FREQUENCY. A wave radiated from the **antenna** of a radio **transmitter** spreads in various directions, the exact nature of its spread being determined by the directional characteristics of the antenna. The part which travels towards the outer atmosphere goes into the **ionosphere** where it acts upon the ionized particles, principally **electrons,** which absorb energy and re-radiate it. The net result of this action is an effective change of the index of refraction of the medium through which the wave is traveling. This causes the wave to be bent back towards the earth, the extent of the bending varying with the index. It is this which causes radio waves to be returned to the earth to give reception at points very remote from the transmitter. However, this change of index of refraction varies with frequency in such a manner that the waves are bent less and less as the frequency is raised. A critical frequency is finally reached where the wave is not bent enough to return to the earth, even for the most glancing angle of incidence which it is possible to obtain. As the frequency of the signal is progressively raised the critical frequencies for the various

layers of the ionosphere are reached in turn, the wave penetrating each at its critical frequency and being refracted back to the earth by the next layer until finally all layers are penetrated and there is no returning signal. This occurs in the vicinity of 40 megacycles. (L.R.Q.)

CRITICAL GRID VOLTAGE. **Thyratron.**

CRITICAL POTENTIAL. **Electrons** are commonly set into motion by an electric field, the energy thus acquired being proportional to the **potential difference** traveled through. If, when moving very rapidly, an electron encounters an atom or a molecule, the latter may be ionized or it may be merely excited; either process involving a change in the relation of one or more of the atomic or molecular electrons to the atom or molecule to which it belongs. Such a change requires a certain minimum amount of energy and unless the moving electron has at least this energy, the ionization or excitation does not take place. The critical potential corresponding to such a process is the potential difference necessary to give the moving electron the requisite energy. For example, the least energy which a cathode particle must have to excite the $K\alpha$ x-radiation of nickel (wavelength 1.662 angstroms) is 7426 **electron volts**, that is, the energy which would be given to it by applying a potential difference of 7426 volts to the x-ray tube. Hence 7426 volts is the critical potential for this excitation. (L.D.W.)

CRITICAL PRESSURE. When a fluid flows through an orifice or a nozzle, the volume of flow from a fixed initial pressure depends on the final pressure as long as that final pressure is in excess of a certain critical pressure. If the final pressure is lower than the critical pressure, the amount of fluid passed will be the same as though the final pressure had been equal to the critical pressure. The critical pressure is a constant proportion of the initial pressure. For example, for air flow it is 53%, for saturated steam, 58%, and for superheated steam, about 56%.

Critical pressure also denotes the pressure of a vapor at its critical point, the latter occurring at a temperature above which the vapor can exist only in the form of a gas. Water, for example, has a critical pressure of 3226 lbs. per sq. in. (See **Critical State.**) (F.T.M.)

CRITICAL SPEED. Because of lack of homogeneity of a body caused by manufacturing difficulties and variations in material densities, it is impossible to distribute the mass of a rotating body about its geometric center. If the shaft on which the body rotates deflects under load, the center of mass may move from the axis of rotation of the shaft. Shaft rotation will then begin about the geometric axis but at some speed the centrifugal force caused by the displacement of the center of mass will equal the deflecting forces on the shaft. The deflecting force may be opposite to and balance the centrifugal force, or the two may be in phase, causing a periodic variation in the radial force on the shaft, which induces a series of vibrations. Since the magnitude of the centrifugal force depends upon the angular velocity and the mass, the vibrations will attain a maximum value at some speed, which is called the critical speed of the shaft. Above the critical speed a state of equilibrium may again be attained in which the body virtually rotates about its mass center. Second, third, and fourth critical speeds are also possible but the amplitudes of the shaft vibration are progressively less. (H.C.H.)

CRITICAL STATE. For every pure substance there is a definite temperature (the critical temperature) and a definite pressure (the critical pressure) at which the liquid and the vapor are indistinguishable. If the liquid substance is enclosed in a hermetically sealed tube with nothing above it but its own vapor, and the temperature is raised, the liquid expands and also evaporates, adding to the vapor; so that the density of the liquid decreases while that of the vapor increases. Ultimately the two densities become equal (the common value being the critical density and its reciprocal the critical specific volume). The surface separating liquid and vapor then becomes invisible; though apparently the surface tension does not altogether vanish until a slightly higher temperature is reached. The pressure attained in this process may be very great; for water it is about 218 atmospheres, the corresponding temperature being 374° C. Above this temperature the substance is said to be a gas, and no amount of compression will cause it to separate into two fluid phases. (See **States of Matter.**)

For certain purposes it is convenient to express the absolute temperature, the pressure, and the specific volume of a substance in terms of their respective critical values, i.e., as abstract ratios T/T_c, p/p_c, v/v_c, called "reduced variables of state." If two gases have two reduced variables of state in common, the third variable will also be approximately the same for the two gases; a principle known as the "law of corresponding states." (L.D.W.)

CRITICAL TEMPERATURE. **Critical State.**

CROCIDOLITE (BLUE ASBESTOS). The mineral crocidolite may be considered as a fibrous variety of the **monoclinic amphibole**, riebeckite. It is also known as a massive mineral. Its hardness is 4; specific gravity, 3.2–3.3; luster, silky to dull; color, blue or bluish-green. It is found in Austria, France, Bolivia, South Africa (the variety known as tiger's-eye), and in the United States in Massachusetts and Rhode Island. The name crocidolite is derived from the Greek, meaning woof, in reference to its fibrous appearance. (E.S.C.S.)

CROCODILE. Reptilia, Crocodilia. Large aquatic **reptiles** of elongate slender form, with short legs, a long compressed tail, and skin armored with bony plates. The crocodiles differ from the related **alligators** and **caiman** in the more tapering snout, although their jaws are much wider than those of the **garial**. Crocodiles are found in southern Asia, Africa, northern Australia, tropical South America, and in southern Florida. Some species occur only in fresh water and others in salt marshes and estuaries. The most common genus is *Crocodilus*.

Crocodiles are much more aggressive and vicious than alligators and are dangerous to man (see also **Fossil Reptiles**). (A.W.L.)

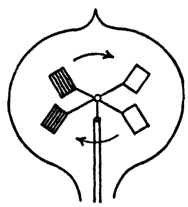
CROCODILIA. An order of large **reptiles** of long slender build. The skin is armed with bony plates and the long jaws bear many conical teeth set firmly in bony sockets. The animals are chiefly aquatic. They are found only in warmer regions and chiefly in fresh water, although some enter the ocean.

The order includes **crocodiles, alligators, caimans,** and the **garial.** (A.W.L.)

CROCOITE. The mineral crocoite, **lead** chromate, corresponds to the formula $PbCrO_4$, and forms prismatic **monoclinic** crystals, often acicular. It is also found in columnar or granular masses. It has a rather distinct cleavage parallel to the prism, and a less distinct cleavage parallel to the base. It has a conchoidal fracture, is sectile; hardness, 2 5–3; specific gravity, 5.9–6.1; luster, adamantine to vitreous; color, red; streak, orange-yellow, translucent. Crocoite is a secondary mineral believed to be formed by waters containing chromic acid acting upon lead minerals like galena, with which it is associated. It is found in Russia, Rumania, Tasmania, Brazil, the Philippines, and Arizona. It is not of com-

mercial value. The name crocoite is derived from the Greek word for saffron in reference to the color of the powdered mineral. (E.S.C.S.)

CROOKES TUBE. Sir William Crookes was a pioneer in the study of electric discharge in gases. In the **vacuum tubes** which he used, and certain forms of which still bear his name, the pressure was reduced to such a point that the bright glow observed at higher pressures practically disappeared. The **cathode rays,** obstructed by but little residual gas, shot straight across the tube and, impinging upon the opposite wall, caused it to glow with greenish fluorescence. By placing an obstacle, such as a metal plate shaped like a Maltese cross, in the path of the rays he was able to demonstrate their rectilinear character by the shadow on the fluorescing surface. In one type of tube he interposed a light paddle-wheel of metallic vanes in the path of the rays, and found it driven at high speed as if by a stream of air. It is, however, probable that the greater part of this effect is due to the heating of the bombarded surfaces and that the paddle-wheel really operates as a Crookes **radiometer.** (L.D.W.)



Four-vane radiometer in bulb.

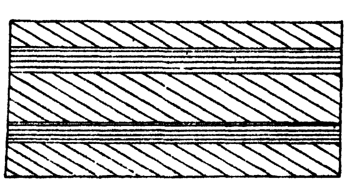
CROP. A thin-walled expanded portion of the alimentary tract (see **Digestive System**) used for the storage of food prior to digestion. Crops are found in many animals, including **earthworms, insects,** and **birds.** (A.W.L.)

CROSS MODULATION. This is an effect produced in radio receivers which results in the **modulation** from one **carrier** being impressed on another carrier. If two modulated carriers are applied to the **grid** of a vacuum **tube** which has appreciable curvature in its operating characteristic, there will be numerous frequency components in the output of the tube. However, following selective or tuning circuits will cut out many of these but there will be certain ones which will not be cut out. Some of these represent the sidebands of the modulation of the undesired signal modulated on the desired carrier. Since they occupy the same frequency band as the desired carrier and its normal modulation there is no way in which they may be cut out and hence upon detection the audio output will contain both the desired and the undesired audio signals. (L.R.Q.)

CROSS PRODUCT OF TWO VECTORS. Vector Product of Two Vectors.

CROSS-BAR SWITCHING. This is a type of automatic telephone switching used for very large service areas. It is characterized by freedom from brushes and sliding contacts, the operation being through magnetically operated mechanisms. (L.R.Q.)

CROSS-BEDDING. Oblique lamination of certain beds in **aeolian** or water-laid **sediments,** caused by current action, is called cross-bedding. Cross-bedded sediments are found especially in river and stream deltas, **alluvial fans and cones, river sand bars and marine sand** deposits, and are also characteristic of **windblown** deposits of all kinds. The different types of cross-bedding are useful criteria for helping to determine the physical (including climatic) conditions under which certain types of clastic sediments were deposited. In regions where the formations have been highly deformed, and possibly overturned, cross-bedding may also be used by the **stratigrapher** and structural geologist to determine the original order in which sedimentary strata were laid down. (R.M.F.)



Cross-bedding (false bedding). (*Field, Laboratory Manual, Princeton University Press.*)

CROSSBILL. Aves, Passeriformes. *Loxia.* Small seed-eating birds (**Aves**) of the northern hemisphere whose mandibles cross at the tip when the mouth is closed. This adaptation enables them to open seeds and fruits, such as cones, very readily. (A.W.L.)

CROSS-FIRE. In nearly all communications circuits the problem of interference from adjacent communication or power circuit must be dealt with. This interference may be between lines of a like nature, between communications lines of different types, or between the communication line and a power circuit. In any event, the net effect is to produce interference which may be merely objectionable noise, or it may be severe enough to cause false operation. When the interference is between two telegraph circuits it is known as cross-fire. The effect is for the signals in one circuit to produce signals and hence false operation in the other. (L.R.Q.)

CROSSHEAD. This is a machine part having reciprocating motion and mounting a pin for the attachment of a connecting rod. In the crank and connecting rod mechanism which is employed to interchange reciprocating and rotating motion, the crosshead is the reciprocating part. It slides between crosshead guides which are attached to the frame. One end of the **connecting rod** is jointed to the crosshead by the wrist pin.

Piston and cylinder engines which are single-acting, that is to say, which have the gas or vapor on one side of the piston only, may have the wrist pin set directly in the piston. A crosshead is essential to a double-acting engine. The piston rod of a double-acting engine must go through a stuffing box or a packing gland in the end of a cylinder, a thing which is impossible for the swinging connecting rod. Some large single-acting engines also have a crosshead so that the wear due to the side thrust of the connecting rod will occur on the easily adjustable crosshead guides instead of the cylinder walls. (F.T.M.)

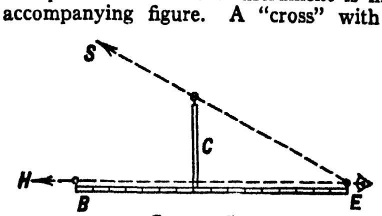
CROSSOVER. Heredity.

CROSS-RATIO. Anharmonic Ratio.

CROSS-SLIDE. Lathe.

CROSS-STAFF. Both the cross-staff and the **astrolabe** were used by navigators for the purpose of measuring **altitude** of celestial objects in the period prior to the invention of the **sextant** in the 18th century. The astrolabe was the more compact of the two, but the use of the cross-staff was simpler and the results slightly more accurate, particularly for small altitudes.

The principle and use of the instrument is illustrated in the accompanying figure. A "cross" with a peep



Cross-staff.

sight in its upper end slides along a rod *EB*. Holding the cross vertical, the observer sights from *E* along the rod toward the horizon at *H*, and slides the cross along until the object under observation appears through the peep sight in the cross. The graduations on the rod indicate directly the value of the angle *HES*, which is the desired apparent altitude. The instrument may also be used to measure the angular distance between any two objects.

Within recent years the instrument has been used to some extent for teaching purposes in elementary courses in astronomy. (W.K.G.)

CROSSTALK. This is the undesirable operating condition of a telephone communication system where the electrical effects of one circuit induce an undesired current in another. In the case of a **phantom** telephone circuit, crosstalk will be troublesome unless the lines with loading coils, terminal equipment, etc., are perfectly balanced electrically. Considerable care must be taken in the manufacture of the loading units in order to minimize crosstalk. (See also **Cross-Fire** and **Morse Thump**. (F.T.M., L.R.Q.)

CROTON. **Spurge Family.**

CROTON BUG. Insecta, Orthoptera. A European **cockroach**, one of the two chief pests of this kind in the United States. Its name is said to be due to its association with water pipes from the Croton reservoir in New York City. (A.W.L.)

CROTONIC ACID. **Alcohols and Ethers.**

CROTONIC ALDEHYDE. **Aldehydes, Ketones, and Related Compounds.**

CROUP. A catarrhal inflammation of the **larynx** occurring in children, characterized by cough, hoarseness, and difficult, noisy inspiration (stridor). The disease usually occurs in attacks at night, and by morning the child is entirely well.

Membranous croup is a synonym for laryngeal **diphtheria.** (D.M.H.)

CROWN. **Belting.**

CROWN SHEET. **Locomotive.**

CROWS. Aves, Passeriformes. Large birds (**Aves**) of the northern hemisphere and Africa. They are black or black and white in color. Together with the ravens,

rooks, magpies, jays, and other species they make up the crow family (Corvidae).

The importance of the common crow of North America, *Corvus brachyrhynchus*, has been debated. He does some good in destroying vermin and insects, but the farmer and conservationist are both against him for his destruction of fruit and grain and the eggs and young of other birds. (A.W.L.)

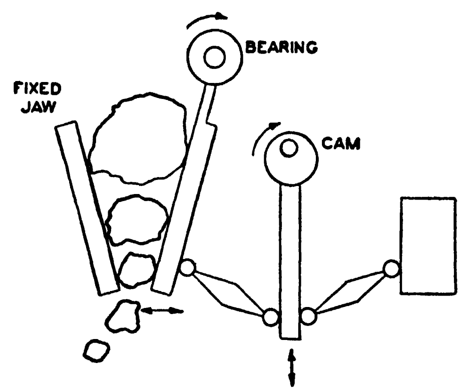
CRUCIBLE. A crucible is a vessel made of heat-resistant material and employed to hold a material that in itself is at high temperature, or is to be subjected to high temperature. Crucibles will range in size from the small laboratory types to large ones having a capacity of several tons of molten metal. They are roughly cup- or barrel-shaped, and are made of some material such as clay. In the laboratory, platinum, iron, and porcelain crucibles are used. In the iron and steel industry, clay crucibles have been used, but at the present time most manufacturers employ the graphite crucible, which is made half and half from graphite and fire-clay, well-mixed, molded, and burned to vitrification. The crucible may be used to hold a material being melted or burned, as in some processes for making steel, where the raw material is put in the crucible, which is then set in a hot furnace until the contents are melted. Or a crucible may be used to receive molten metal, which has been produced elsewhere, as from a brass furnace or cupola, in which case it is the means for conveying it from the point of melting to the point of casting, serving thus as the intermediate reservoir between the furnace and the mold. (See **Casting.**) (F.T.M.)

CRUDE OIL. **Petroleum; and Hydrocarbons.**

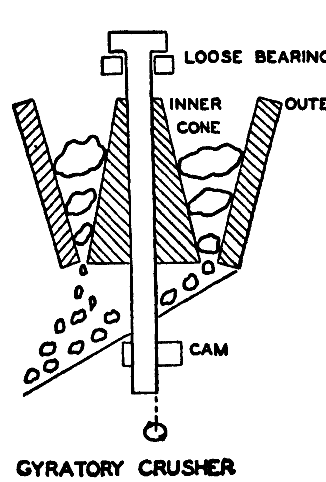
CRUSH BRECCIAS. **Autoclastic.**

CRUSHING AND GRINDING. Machines for the mechanical subdivision of solids are usually classified as coarse crushers, intermediates and fine grinders.

The best known types of coarse crushers are jaw crushers and gyratory crushers. A typical jaw crusher, the Blake, consists of a set of vertical jaws, one jaw being

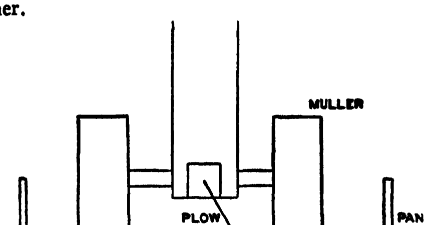


JAW CRUSHER

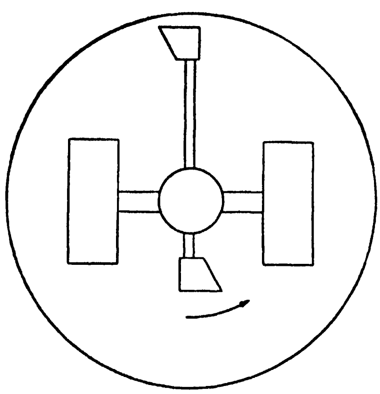


GYRATORY CRUSHER

fixed while the other moves back and forth by a cam and pitman arrangement. The jaws are farther apart at the top than at the bottom so that the material is progressively crushed smaller as it travels down the jaws, falling through the bottom when it becomes small enough. The movement of the jaw may therefore be small since the complete crushing is not performed with one stroke. A gyratory crusher consists of inner and outer vertical crushing cones. The inner cone, apex upward, is inverted with respect to the outer. The inner cone has a slight circular movement, but does not rotate. The movement is given to the cone shaft by a cam arrangement. Its crushing action is similar to that of the jaw crusher.

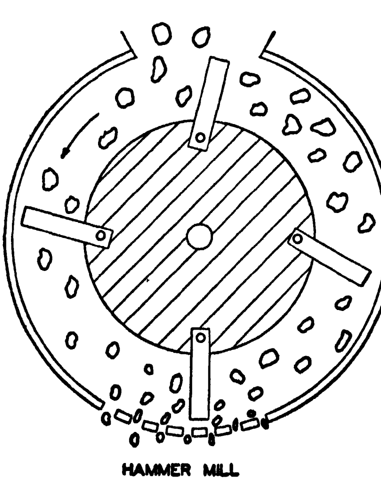


One type of intermediate crusher is a set of crushing rolls. A set consists of two horizontal cylinders placed close together and rotating in opposite directions so as



EDGE RUNNER

to "nip" and crush pieces of material between them. Another type is the edge runner. This type consists of a pan in which rotate two or more heavy wheels known as mullers. The material is shoved under the wheels by

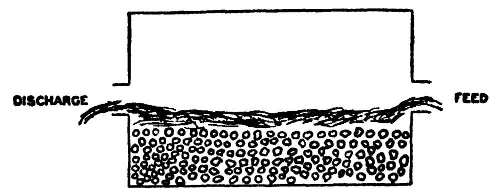


HAMMER MILL

plows. Grinding and mixing are often performed together, particularly on soft materials such as clay.

Hammer mills involve the principle of impact rather than pressure. Bars, hinged to disks attached to a horizontal rotating shaft, strike the material, enclosed in a cage, until it is fine enough to drop through the bottom openings. This type is usually used on soft material such as coal.

The ball mill is a typical fine grinder. A slightly inclined or horizontal rotating cylinder containing balls,



BALL MILL

usually stone or steel, grinds the material to the necessary fineness by the rubbing and impact of the tumbling balls. The feed is at one end and the discharge at the other. This is largely used in the **Portland cement** industry. Buhrstone mills, also for fine grinding, are similar to the old-fashioned flour mill. With modern mechanical refinements these are used in the **paint** industry. (D.E.M.)

CRUSTACEA. The **lobsters, crabs, barnacles, shrimps,** and many other species, constituting a class of the phylum **Arthropoda.** A large majority of the 25,000 known species are aquatic.

The Crustaceans are distinguished from other classes of the phylum by the following characters: 1. The body is divided into **cephalothorax** and abdomen. 2. The eyes are compound. 3. Two pairs of **antennae** are present. 4. Jointed appendages are found on the abdomen in many species. 5. Respiration is usually accomplished by gills.

The principal economic importance of crustaceans is due to the value of some species as food. Lobsters, shrimps, and some of the crabs are caught in large numbers for the market and are regarded as delicacies. Although formerly cheap, the lobster has been caught in such large numbers on the New England coast that it now has to be protected by law and brings high prices. The smaller crustaceans are important as food for fishes.

Barnacles have long been a nuisance for their part in the fouling of ship bottoms.

The following brief outline indicates the complexity of classification of the crustaceans.

Subclass **Branchiopoda.** At least four pairs of broad fringed appendages on the thorax. **Carapace** usually present.
- Order Phyllopoda. Appendages similar, numerous. Fairy shrimp.
- Order Cladocera. Usually with a bivalve carapace. **Water fleas.**

Subclass **Ostracoda.** With a bivalve carapace. Thorax with only two pairs of appendages or less. *Cypris.*

Subclass **Copepoda.** No carapace. Thorax with five pairs of appendages. *Cyclops* and the parasitic fish-lice.

Subclass **Cirripedia.** Sessile as adults. Barnacles and parasitic forms.

Subclass **Malacostraca.** Carapace normally present. Many appendages on thorax and abdomen.
- Order Leptostraca. Like Phyllopoda but abdominal appendages slender.
- Order Hoplocarida. Larger predacious species. **Mantis shrimps.**

Order Syncarida. A small group of rare forms.
Order Mysidacea. Also very limited.
Order Cumacea. A few small marine species.
Order Tanaidacea. Small marine order, sometimes included in the following.
Order Isopoda. Marine, fresh-water and terrestrial forms. Oval and flattened. No carapace. The sow-bugs, pill-bugs or wood-lice and other species.
Order **Amphipoda.** Related to the preceding but body high and narrow.
Order Euphausiacea. **Cephalothorax** covered with a shield. Marine species. Thoracic appendages biramous.
Order **Decapoda.** Cephalothorax with shield. Thoracic appendages with one branch. **Lobsters, crabs, crayfishes, shrimps,** etc. (A.W.L.)

CRYOLITE. Cryolite, **sodium aluminum fluoride,** Na_3AlF_6, crystallizes in the **monoclinic** system but in forms that closely approach cubes and **isometric octahedrons.** It is usually found massive. Cryolite has an uneven fracture, is brittle; hardness, 2.5; specific gravity, 2.95–3.0; luster, vitreous to greasy; color, snow-white but may be colorless, reddish or brownish; translucent to transparent. The only considerable occurrence of cryolite is at Ivigtut, Greenland, where veins of this mineral are associated with granites and **gneisses.** Small occurrences of cryolite have been noted in the Ilmen Mountains, Russia, and at Pike's Peak, Colorado. Cryolite has its chief use in the electrolytic production of **aluminum,** but small amounts are employed in the manufacture of opalescent glass.

The name cryolite is derived from the Greek words meaning frost (ice) and stone in reference to its translucency. (E.S.C.S.)

CRYOLOGY. That branch of **hydrology** which is concerned with **snow** and ice. (R.M.F.)

CRYPTOBRANCHUS. Hellbender.

CRYPTOCRYSTALLINE. When the texture of a rock is so finely **crystalline** (that is, made up of such minute crystals) that its crystalline nature is but vaguely revealed even in a thin section by transmitted **polarized light,** the rock is said to be cryptocrystalline. Among the **sedimentary** rocks, **chert** and **flint** are cryptocrystalline. Lava flows, especially of the **acidic** type such as **felsites** and **rhyolites,** may have a cryptocrystalline ground mass as distinguished from pure **obsidian** (acidic), or **tachylite** (basic), which are natural rock glasses. (R.M.F.)

CRYPTOMONADIDA. An order of 1-celled animals containing species of constant body form, with **flagella. Mastigophora.** (A.W.L.)

CRYPTOZOA. Paleobotany.

CRYPTURIFORMES. An order of ground birds (**Aves**) resembling the game birds. They range through South America and north into Mexico, and are called partridges by inhabitants of these countries. The tinamous (**tinamu**). (A.W.L.)

CRYSTAL. There are two types of crystals which are used in communications work, the rectifying and the piezo-electric. Among the first may be mentioned galena, silicon and silicon carbide. All have the property of passing current in one direction and not in the other, or in some cases unequally in the two directions. Since demodulation or **detection** is fundamentally a process of rectification these crystals may be used as detectors of modulated radio signals.

The piezo-electric crystal has the peculiar property of giving a voltage across certain faces when a mechanical pressure is applied to other faces. Among crystals exhibiting this effect are Rochelle salt and quartz, the first being by far the most active but the second being much stronger mechanically. These crystals are used in numerous ways in communications circuits. Rochelle salt is used for **microphones** where the sound waves striking the crystal produce corresponding voltages which are amplified for use, for phonograph pickups where the pressure is produced by the needle linkage (see **Crystal Pickup**), for **loud-speakers** and head-phones where use is made of the reversibility of the process, i.e., the voltage is applied and it causes the other faces physically to move. Quartz is widely used for frequency control of radio transmitters (see **Oscillator**), for **filters** in telephone **carrier** circuits and for very sharp tuning in **receivers.** (See also **Piezo- and Pyro-Electric Phenomena; Crystalography.**) (L.R.Q.)

CRYSTAL ANALYSIS. Crystal Structure.

CRYSTAL AXES. Crystallography.

CRYSTAL CONTROL. Oscillator.

CRYSTAL FORM. Crystallography.

CRYSTAL OSCILLATOR. Piezo-Electricity and Pyro-Electricity.

CRYSTAL PICKUP. Since piezo-electric **crystals** produce electrical voltages when subjected to mechanical stresses they offer possibilities for various electromechanical processes. One of these is the phonograph pickup, where the phonograph needle operating in the groove of the record must transmit mechanical motion to something which will convert it into electrical effects so vacuum-tube **amplifiers** may be used. The crystal is one of the most sensitive and at the same time one of the highest fidelity devices for doing this. While many crystals exhibit the piezo-electric effect, Rochelle salt is the most sensitive and is used for pickups, microphones, etc. Through a mechanical linkage the motion of the needle is transmitted into mechanical stresses on the crystal and hence produces electrical effects which may be amplified and then converted to sound by the **loud-speaker.** (L.R.Q.)

CRYSTAL PLANE. Crystallography.

CRYSTAL STRUCTURE. Long before the epochal experiments performed at the suggestion of von Laue by Friedrich and Knipping, it was inferred that the structure manifestly existing in crystals is due to an orderly arrangement of **atoms** or **molecules.** The ideal crystal is traversed by systems or "families" of parallel cleavage planes in various directions, three or more of which determine the normal external shape of the natural crystal. It is easy to imagine that these planes form a space lattice of equal polyhedral cells fitting together to fill the space, much as do the cells of a honeycomb or an egg-crate; and further, that each of the individual cells represents a characteristic unit grouping of particles, a structure built of atoms or of ions, perhaps the molecule itself.

Dr. Max von Laue (Munich) in 1912 hit upon a method of verifying and elaborating this theory. He knew from the density and atomic weights, that the number of atoms in a cc. of rock salt, for example, is about 4.488×10^{22}, and that therefore, if they are equally spaced in all three directions, their distance apart is 2.814×10^{-8} cm. or 2.814 angstroms. Certain **quantum theory** calculations had already indicated that **x-rays** have wavelengths of this order. It occurred to von Laue that if a beam of x-rays were directed upon a crystal and the crystal turned into a suitable position, one might observe **interference** maxima analogous to

those produced with light by a **diffraction grating.** This proved to be the case, and the result verified beyond question the existence of regular spacings between reflecting planes of some sort, presumably plane arrays of atoms or ions.

Subsequent analysis of the problem by Bragg resulted in a formula analogous to that for interference of light reflected by thin plates. If the reflecting layers are spaced at equal distances d, and if the wavelength of the incident x-rays is λ, the angle θ between rays and layers necessary for an interference reflection maximum is given by **Bragg's law,** viz., $\sin\theta = n\lambda/2d$; in which n is an integer. By slowly turning the crystal, the various plane-families are brought into suitable orientations for the production of maxima. The result is a Laue pattern of black spots on the photographic plate placed beyond the crystal to catch the reflections. Another method, developed by Hull and by Debye and Scherrer, secures the necessary angular variation by crushing the crystal to powder and relying upon the fortuitous orientation of the fragments; the pattern in this case being a system of concentric rings.

While it is very easy, when one knows the structure of the crystal and the wavelength of the rays, to predict the diffraction pattern, it is quite another matter to deduce the crystal structure in all its details from the observed pattern and the known wavelength. This can be done, however, and we now have determined the arrangement and spacings of atoms in nearly all known crystals. Stereoscopic models of many typical crystals are to be found in an excellent album prepared by von Laue and Mises, entitled *Stereoscopic Drawings of Crystal Structure.* (L.D.W.)

CRYSTAL SYSTEMS. **Crystallography.**

CRYSTALLINE CONE. A glassy body between the cornea and the sensory portion of each component of the compound **eye** in some species of insects. (A.W.L.)

CRYSTALLINE STYLE. A digestive secretion of certain **bivalve** mollusks. It consists of protein bearing an amylolytic ferment and is produced in a continuous rod by a pouch of the intestine. One end projects into the stomach and is worn away by contact with a gastric shield and mixed with the food. (A.W.L.)

CRYSTALLIZATION. The phenomena, which are involved in the production of crystals, suggest consideration of the following topics:

1. Crystals proper. (See **Crystallography.**)
2. The process of crystallization. (See below.)
3. The converse process of crystal disappearance. (See **Dissolving.**)
4. The prevention of crystal formation. (See **Colloidal State, Condensation Processes** (6).)
5. Solutions proper. (See **Solutions and Solubility.**)

The Process of Crystallization. Crystals are formed (1) from solution, (2) from fusion, (3) by sublimation.

(1) The formation of crystals from solution, starting with an unsaturated solution, takes place when a solution is evaporated or cooled below the saturation point, except as retarded by supersaturation. Supersaturation is prevented by the addition of seed crystals of the substance. Since, in the case of the majority of soluble substances, solubility increases with increase of temperature cooling below the saturation point favors the formation of crystals. In very few cases, such as sodium sulfate above 32.4° C., **calcium** sulfate (slightly soluble), calcium **hydroxide** (slightly soluble), solubility decreases with increase of temperature, and the above statement would not apply. A case of wide scope and great importance is that of crystal formation by **precipitation** upon mixing two solutions. Actually, this is the same as for substances of greater solubility, since the substance precipitated is first formed in solution and the excess above the saturation point separates as precipitate. As a rule the crystals are larger and more perfect the slower their growth. Conversely, when small crystals are desired, rapid stirring and quick cooling are practical. The smaller the crystals of a given substance, the purer the material generally is. Small crystals may be increased in size by allowing them to stand in the mother liquor before separation.

(2) The formation of crystals from fusion takes place when the melted substance is cooled sufficiently slowly near and below the fusion point. If the cooling is rapid the fusion may result in the formation of an undercooled liquid of rigidity corresponding to a solid. Glasses, whether artificial, such as glass, vitreous enamels, and slags, or natural, such as vitreous rocks and minerals, e.g., obsidianite, are under-cooled liquids. Rocks and minerals which have cooled sufficiently slowly from fusion form crystals, for example, granite.

(3) The formation of crystals by **sublimation** takes place when the vapor of a substance is condensed as a solid without passing through the liquid phase in so doing. This occurs when the temperature of the condenser is below that of the melting point of the substance. (See **Vapor Pressure.**)

The heat of crystallization is in amount the same as the heat of solution of a given substance but of opposite sign. (R.K.S.)

CRYSTALLOBLASTIC. Designating the textures of metamorphic rocks resulting from recrystallization under differential and directed pressures and high viscosity. (See also **Riecke's Principle.**) (R.M.F.)

CRYSTALLOGRAPHY. This branch of physical science deals with the external shapes of crystals and with the geometrical relations between the atomic planes within them. If a solid crystal is broken, it is found to have separated along certain "cleavage planes" into polyhedral fragments. Even when crushed to powder, the minute grains show this characteristic. Measurements upon the variously shaped pieces reveal that if they were fitted together again, the planes would all be found to belong to one or another plane-family, the members of any one of which are all parallel.

In most crystal systems each of the more prominent crystal faces belongs to one of three plane-families intersecting along what are called the crystal axes. (In the hexagonal system there are four.) These may be conveniently used as coordinate axes, X,Y,Z, though they are not generally at right angles. Haüy discovered that if the ratio of the intercepts of two crystal planes on one of these axes is a simple fraction, such as $3/5$, the ratios of the intercepts on the other axes are likewise simple. This suggests that the two intercepts on any one axis are multiples of a common unit. The units are, however, generally different for the different axes, bearing to each other ratios called the axial ratios.

It is more convenient to use the reciprocals of the intercepts. For example, a plane might have intercepts equal to 10,000, 15,000, and 6000 of the respective units. The reciprocals have the ratios $\frac{1}{10{,}000}:\frac{1}{15{,}000}:\frac{1}{6000}$, which in lowest terms are $3:2:5$. These smallest integers are the Miller indices of the family to which this plane belongs, and the family is thus designated (325). The family (201) is parallel to the Y axis but intersects the X and Z axes. (The hexagonal system has four Bravais-Miller indices for each plane-family.)

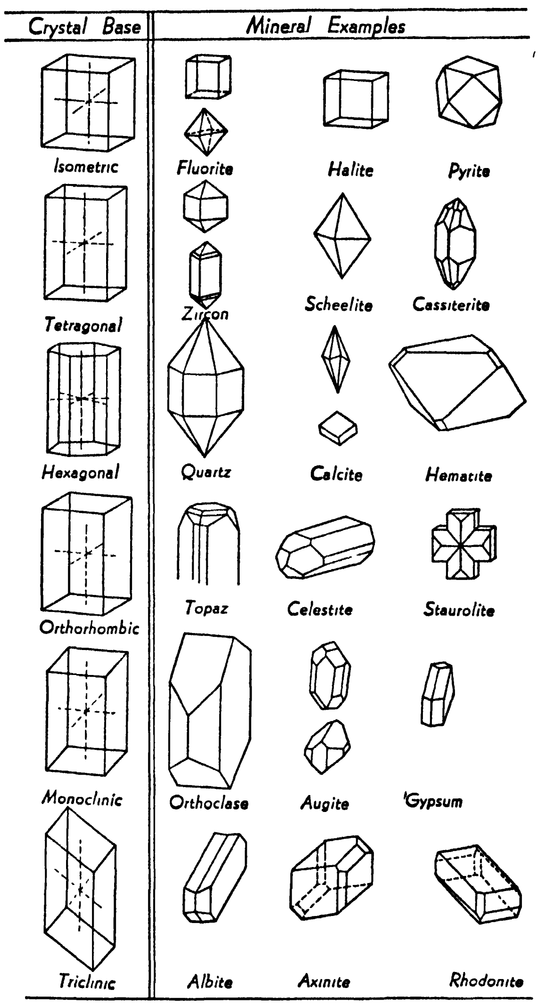
Close study of the angles, indices, and axial ratios long since made it clear that every crystalline substance has a structure built upon a space "lattice" characteristic of the substance. We now know that this is due to the regular arrangement of the atoms, molecules, or ions composing the substance. (See **Crystal Structure.**) The same study shows that the lattice structures of all

crystals may be classified into fourteen types, which are divided into six "systems" as follows:

1. **Isometric.** Three axes of equal length which intersect at right angles, with axial ratios all unity.

2. **Tetragonal.** Three axes which intersect at right angles. Two horizontal axes of equal length, and a vertical axis which is either longer or shorter than the horizontals. (Only one axial ratio is unity.)

3. **Hexagonal.** Four axes which intersect at right angles, three coplanar axes at 120°, and one at right angles to them. The two horizontal axes of equal length, and the vertical axes either longer or shorter than the horizontals.



Illustrating the six crystal systems and specific examples of each system. (*Field, Outline, Barnes & Noble.*)

4. **Orthorhombic.** Three axes of different lengths which intersect at right angles, and none of the axial ratios unity.

5. **Monoclinic.** Three axes of different lengths, two of which intersect at right angles, the third oblique to one of the others.

6. **Triclinic.** The axes of unequal length and all oblique to one another, and none of the axial ratios unity. The angles between axes are less than 90°, and are unequal.

Practically all minerals are crystalline, although perfect natural crystals are seldom, if ever, found. Because of the laws of crystallography, however, a crystallographer can usually determine the crystal form of a known species from a fragment of the original crystal, provided that at least two of the crystal faces are visible. Crystalline aggregates are said to be **cryptocrystalline** when the individual particles are proved to have crystalline structure but their crystal faces are exceedingly small or indistinguishable. A mineral is **pseudocrystalline** if its external form does not correspond with its crystalline structure. (L.D.W., R.M.F.)

CTENIDIAL FILAMENTS. Slender processes of the **ctenidia** of mollusks (**Mollusca**). (A.W.L.)

CTENIDIUM. A projection of the body wall of mollusks (**Mollusca**), lying in the mantle cavity and usually serving as a gill. Ctenidia are slender filaments or leaf-like plates. (A.W.L.)

CTENOPHORA. The comb jellies or sea walnuts, constituting a small phylum of marine animals related to the coelenterates and sometimes included in that phylum. The phylum includes the peculiar **Venus' girdle,** a transparent ribbon-like animal whose longitudinal axis is across the middle of the slender body.

The ctenophores differ from the coelenterates in the following structures: 1. The alimentary tract opens to the exterior at the end of the body opposite to the mouth. 2. The body bears rows of ciliated (see **Cilium**) plates, the combs which give the animals one of their common names. These are organs of locomotion. 3. **Colloblasts** or adhesive cells take the place of **nematocysts.**

Classification:

Class Tentaculata. With a pair of long tentacles.
- Order **Cydippida.** Body spherical to cylindrical. Tentacles long.
- Order **Lobata.** Tentacles replaced in adult by fringe of short tentacles around mouth.
- Order **Cestida.** Body ribbon-like. Venus' girdle.

Class Nuda. Tentacles absent. Body conical to ovoid. (A.W.L.)

CUBEB. **Piper Cubeba, Pepper.**

CUBIC EQUATIONS. A cubic equation in one unknown is a **polynomial equation** of the third degree, and has the general form

$$a_0x^3 + a_1x^2 + a_2x + a_3 = 0.$$

The general cubic equation $y^3 + py^2 + qy + r = 0$ may be reduced by the substitution $y = x - \frac{1}{3}p$ to the normal form $x^3 + ax + b = 0$, where $a = \frac{1}{3}(3q - p^2)$, $b = \frac{1}{27}(2p^3 - 9pq + 27r)$.

The normal form $x^3 + ax + b = 0$ has roots x_1, x_2, x_3 given by

$$x_1 = A + B,\ x_2, x_3 = -\tfrac{1}{2}(A + B) \pm \tfrac{1}{2}\sqrt{3}\,i(A - B),$$

where $i = \sqrt{-1}$, and

$$A = \sqrt[3]{-\frac{b}{2} + \sqrt{\frac{b^2}{4} + \frac{a^3}{27}}},\quad B = \sqrt[3]{-\frac{b}{2} - \sqrt{\frac{b^2}{4} + \frac{a^3}{27}}}.$$

If a and b are real, and

(1) if $\frac{b^2}{4} + \frac{a^3}{27} > 0$, there are one real root and two conjugate complex roots,

(2) if $\frac{b^2}{4} + \frac{a^3}{27} = 0$, there are three real roots of which two are equal,

(3) if $\frac{b^2}{4} + \frac{a^3}{27} < 0$, there are three real and unequal roots.

In case (3), where $\frac{b^2}{4} + \frac{a^3}{27} < 0$, the above formulae for

the roots are not in convenient form for numerical calculation; a trigonometric transformation reduces them to better form, thus: if $\cos\phi = \sqrt{\frac{b^2}{4} \div \left(-\frac{a^3}{27}\right)}$, then the roots are

$$x_k = \mp 2\sqrt{-\frac{a}{3}}\cos\left(\frac{1}{3}\phi + k\cdot 120^\circ\right) \quad (k = 0, 1, 2),$$

where the upper sign is to be used if $b > 0$ and the lower sign if $b < 0$.

If $\frac{b^2}{4} + \frac{a^3}{27} > 0$, the real root is given in convenient form for numerical calculation by the trigonometric form

$$x = \pm 2\sqrt{\frac{a}{3}} \cdot \cot 2\phi,$$

where

$$\tan\phi = \sqrt[3]{\tan\psi} \quad \text{and} \quad \cot 2\psi = \sqrt{\frac{b^2}{4} + \frac{a^3}{27}},$$

and where the upper sign is to be used if $b > 0$ and the lower sign if $b < 0$.

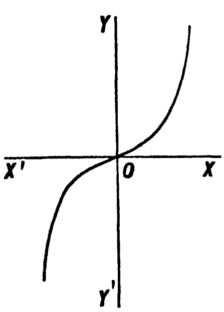
If $\frac{b^2}{4} + \frac{a^3}{27} = 0$, the roots are

$$x = \mp 2\sqrt{-\frac{a}{3}}, \quad \pm\sqrt{-\frac{a}{3}}, \quad \pm\sqrt{-\frac{a}{3}},$$

where the upper sign is to be used if $b > 0$ and the lower if $b < 0$. (L.L.S.)

CUBIC FUNCTIONS. A cubic function is a **polynomial function** of the third degree, which is therefore of the form $ax^3 + bx^2 + cx + d$, where a, b, c, d are **constants** (independent of x) and x is the **variable.** (L.L.S.)

CUBICAL PARABOLA. This is a curve obtained by plotting the **graph** of the equation $a^2y = x^3$. Its shape is shown in the accompanying figure. (L.L.S.)

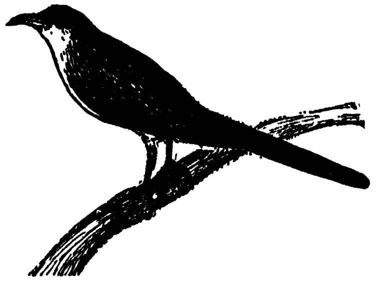


Cubical parabola.

CUBOMEDUSAE. An order of **jellyfishes** of roughly cuboidal form. (A.W.L.)

CUCKOO. Aves, Cuculiformes. Birds (**Aves**) of many species found in all continents. They take their common name from the call of the European cuckoo, *Cuculus canorus.* This species, like some others of the family, is well known for its habit of leaving its eggs in other birds' nests.

Some species are known by other names, including koel, coucal and malkoha. North America has two species, the yellow-billed, *Coccyzus americanus,* and black-billed, *C. erythrophthalmus,* and the related ani and roadrunner of the South and Southwest. (A.W.L.)



Yellow-billed cuckoo. A long slender bird, grayish brown above, whitish below, with white marks on the ends of the tail feathers; lower part of beak yellow.

CUCKOO WASP. Insecta, Hymenoptera. Small **wasps** which lay their eggs in the nests of solitary wasps and bees. Usually metallic blue or green. Family Chrysididae. (A.W.L.)

CUCULIFORMES. The order of birds (**Aves**) which includes the **cuckoos,** anis, **road-runners,** quezal, and related species. (A.W.L.)

CUCUMBER. *Cucumis sativus.* **Gourd Family.**

CUCUMIS. **Gourd Family.**

CUCURBITA. **Gourd Family.**

CUESTA. **Scarp.**

CULM. **Mississippian Period.** Also the stem of a grass. **Grass Family.**

CULTURE. The growth and propagation of microorganisms by artificial means outside of the body. This is done in various media such as agar, bouillon, gelatin—either plain or enriched with blood, tissue or dextrose. The materials from the patients which are cultured commonly are blood, urine, tissue, any body secretion or material taken directly from the site of infection, such as pus from an abscess. (D.M.H.)

CULVERT. An artificial waterway for carrying water under an obstruction, such as a highway or railway, is a culvert. The culvert is a drainage structure that completely encloses the opening for the water. and is covered by a fill over which the roadway passes. It is differentiated from the bridge by virtue of the fact that it conveys water while the latter spans an opening It is composed of a barrel (the essential part) and head walls at the ends of the barrel The latter prevent erosion of the soil adjacent to the culvert and divert the water into the barrel. Head walls are not always employed. Culverts are constructed of **concrete,** cast iron, **brick,** terra cotta, and corrugated sheet metal. Small ones are usually circular or rectangular in shape. Larger culverts may be arched over a curved invert. (F.T.M.)

CUMACEA. An order of **crustaceans** made up of a few marine species of small size. (A.W.L.)

CUMMINGTONITE. The mineral cummingtonite is a variety of **amphibole** which is essentially (Mg, Fe) SiO_3, the amounts of **magnesium** and **iron** varying as they replace one another. Cummingtonite is generally restricted to material containing from 50–70% $MgSiO_3$. The name *grünerite* has been applied to cummingtonite which contains more than 50% of the $FeSiO_3$ molecule. Cummingtonite usually occurs as a brown fibrous to lamellar mineral. It derives its name from Cummington, Massachusetts. (E.S.C.S.)

CUMULATIVE FREQUENCY DISTRIBUTION. The cumulative frequency distribution is found by adding all the **variates** below a certain point, generally the closed **class limits.** It is useful in finding any measure of position and is needed to construct the **ogive.** We note that the **distribution function** is the mathematical counterpart of the cumulative frequency distribution. The cumulative frequency distribution may also be found (for variates above any point) by adding all the variates above a certain point. (L.A.A.)

CUMULATIVE METHOD. **Physical Measurements.**

CUMULONIMBUS. Clouds.

CUMULOSE. The term proposed by Merril in 1897 for **sediments** composed almost, if not entirely, of **carbonaceous** material, such as peat, lake mucks, etc. (R.M.F.)

CUMULUS. Clouds.

CUPOLA. In geology, cupola is the term proposed by R. A. Daly in 1911 for a subsidiary dome-like protrusion in the roof of a **batholith.** Cupolas are supposed to be the reservoirs for the concentrated rising gases of the batholithic **magma** and may serve as the loci for **volcanoes.** (R.M.F.)

CUPOLA FURNACE. The cupola is the furnace commonly employed in foundries for the melting of cast iron. In principle, the cupola is similar to, but simpler than, the **blast furnace.** Like the latter, it has a sheet-metal shell and is lined with refractory brick. It is similar, also, with respect to the admission of air through tuyeres, but unlike the blast furnace, it rarely uses preheated air, nor is there any attempt to save the heat in the waste gases. Accordingly, it is not necessary to provide the air lock at the upper end, as on the blast furnace. The top of a cupola is simply a stack discharging the products of combustion to the atmosphere. The cupola is fed with materials from an opening in the side above the line to which the charging is carried. It has an iron notch and a slag spout, and a hearth much like the blast furnace.

When it is ready to be charged, the hearth is lined with a refractory material such as sand, containing sufficient clay to bind it together to keep it from floating on the iron. A certain amount of kindling wood is then charged, on which is placed a bed layer of coke to an amount sufficient so that when the kindling has burned out and the coke has settled to the bottom of the cupola, it will form a bed extending above the tuyeres. As soon as the bed charge is well lighted additional charges of coke, scrap, pig iron, and limestone are added until the upper limit of charge depth is reached. This is allowed to burn some time under the influence of a small quantity of air so as to "soak" thoroughly the contents with heat. The cupola is then ready for the "blast." A blower is started, and air is rapidly forced through the tuyeres, resulting in a very high rate of combustion, and the production of a high temperature just above the tuyeres. As the coke burns out, and the iron sinks into this high-temperature region, it is melted, falls in drops and streams to the hearth, and runs out through the iron notch. The cupola operator allows a certain amount of this iron to run out at the beginning of a heat, as it is usually not sufficiently liquid to pour well. He then closes the iron notch with a bott, which is a cone of clay designed to cork the opening. The melting continues and molten iron is accumulated in a pool over the hearth. As successive charges sink lower inside the cupola, fresh charges are added to the extent of the iron required for that particular run. The operator judges this amount of iron accumulated by knowing the characteristics of his cupola, and noting the elapsed time of melting between successive tappings. When tapping a cupola, the clay bott is carefully cleaned out until only a thin wall remains between the iron notch and the interior pool. This is broken with a long tapping chisel. As the molten iron gushes forth it is caught in **crucibles,** in which it is carried to the molds. When a crucible has been filled the flow is stopped by inserting another bott in the tapping hole. This succession of tappings goes on until all the molds have been poured. Some cupolas are sufficiently large to melt at a rate equal to that at which the iron can be used, and the iron notch is not plugged. Iron is allowed to run continuously from the spout, fresh crucibles being placed under the spout as soon as the preceding one is filled. Although a blast furnace is often operated continuously for days at a time, a heat in an average cupola in a jobbing foundry usually consumes only 2 or 3 hours; and in a production factory rarely exceeds 8 to 10 hours. (F.T.M.)

CUPR(IC), (OUS). Copper.

CUPRITE. The mineral cuprite, **cuprous** oxide, Cu_2O, occurs as **isometric** crystals, usually **octahedrons,** but may be cubes, **dodecahedrons** or modified combinations. It also is found as a massive, earthy material. Its fracture is conchoidal to uneven; brittle; hardness, 3.5–4; specific gravity, 5.85–6.15; luster, submetallic to earthy; color, red; nearly transparent to nearly opaque. Its streak is shining brownish-red. Cuprite is a secondary mineral resulting doubtless from the oxidation of copper sulfides. It is often found associated with native copper, **malachite** and **azurite.**

Cuprite is a fairly common mineral, and of the many localities in which it occurs may be mentioned the Province of Perm, Russia; Chessy, France; Broken Hill, New South Wales; Corocoro, Bolivia; Andacollo, Chile; Bisbee, Arizona; and Del Norte County, California. The name cuprite is derived from the Latin cuprum, copper. (E.S.C.S.)

CUPRUM. Copper.

CURARE POISON. Strychnine.

CURASSOW. Aves, Galliformes. Birds (**Aves**) of a few species found in northern South America. They are about the size of turkeys and are arboreal in habit. Excellent as food and sometimes domesticated. (A.W.L.)

CURETTAGE. The scraping of an organ, a bony cavity or some other portion of the body with a curet—a spoon-shaped sharp-edged instrument. It is commonly spoken of in relation to the uterus, where the lining of the organ is removed with a curet either for diagnostic examination, or as a procedure to terminate pregnancy. (R.S.M., D.M.H.)

CURIE. The curie is a unit used in measuring the amount of emanation from **radium.** It is that amount which is in radioactive equilibrium with 1 gram of radium. (R.S.M.)

CURIE POINT. Curie-Weiss Law.

CURIE-WEISS LAW. It is well known that iron and other ferromagnetic substances do not exhibit magnetic properties at high temperatures. The change with rising temperature is gradual, but at a certain temperature, known as the Curie point, occurs a transition from ferromagnetic to paramagnetic properties, and likewise a change in the dependence of the magnetic susceptibility upon the temperature. (See **Magnetism.**) P. Curie stated in 1895 that above this point the susceptibility varies inversely as the absolute temperature. But this was found to be not generally true, and was modified in 1907 by P. Weiss to state that the susceptibility of a paramagnetic substance above the Curie point varies inversely as the excess of the temperature above that point. At or below the Curie point, the Curie-Weiss law does not hold. (L.D.W.)

CURIUM. Chemical Composition, I. Elements.

CURL OF A VECTOR FUNCTION. Let $\mathbf{v}$ be a vector **function** of position, with rectangular components v_1, v_2, v_3. The vector expression

$$\nabla \times \mathbf{v} = \hat{\mathbf{i}}\left(\frac{\partial v_3}{\partial y} - \frac{\partial v_2}{\partial z}\right) + \hat{\mathbf{j}}\left(\frac{\partial v_1}{\partial z} - \frac{\partial v_3}{\partial x}\right) + \hat{\mathbf{k}}\left(\frac{\partial v_2}{\partial x} - \frac{\partial v_1}{\partial y}\right)$$

$$= \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ v_1 & v_2 & v_3 \end{vmatrix}$$

is called the curl of $\mathbf{v}$, and is denoted by curl $\mathbf{v}$. It is also sometimes called the rotation of $\mathbf{v}$ and denoted by rotation $\mathbf{v}$.

If $\mathbf{r} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$ is a variable vector and $\mathbf{a}$ is a constant vector, then

$$\text{curl } \mathbf{r} = \nabla \times \mathbf{r} = 0,$$
$$\text{curl } (\mathbf{r} \times \mathbf{a}) = \nabla \times (\mathbf{r} \times \mathbf{a}) = -2\mathbf{a}.$$
$$\text{curl } (r\mathbf{a}) = \nabla \times (r\mathbf{a}) = \frac{\mathbf{r} \times \mathbf{a}}{r}.$$

Let $\mathbf{u}$ and $\mathbf{v}$ be vector functions of position, and let u be a scalar function of position, then

$\text{curl } (\mathbf{u} + \mathbf{v}) = \nabla \times (\mathbf{u} + \mathbf{v}) = \nabla \times \mathbf{u} + \nabla \times \mathbf{v} = \text{curl } \mathbf{u} + \text{curl } \mathbf{v},$

$\text{curl } (u\mathbf{v}) = \nabla \times (u\mathbf{v}) = (\nabla u) \times \mathbf{v} + u(\nabla \times \mathbf{v}),$

$\text{curl } (\mathbf{u} \times \mathbf{v}) = \nabla \times (\mathbf{u} \times \mathbf{v}) = \mathbf{u}(\nabla \cdot \mathbf{v}) - \mathbf{v}(\nabla \cdot \mathbf{u}) + (\mathbf{v} \cdot \nabla)\mathbf{u} - (\mathbf{u} \cdot \nabla)\mathbf{v},$

$\text{curl } (\text{curl } \mathbf{v}) = \text{curl}^2\mathbf{v} = \nabla \times (\nabla \times \mathbf{v}) = \nabla(\nabla \cdot \mathbf{v}) - (\nabla \cdot \nabla)\mathbf{v} = \text{grad } (\text{div } \mathbf{v}) - \nabla^2\mathbf{v},$

$\text{curl } (\text{grad } u) = \nabla \times (\nabla u) = 0,$

$\text{div } (\text{curl } \mathbf{v}) = \nabla \cdot (\nabla \times \mathbf{v}) = 0.$

Let $\mathbf{v}$ be a vector function of position, let δ be a small region of space and also its volume, surrounding a point P, and let ω be the bounding closed surface of δ and let $d\sigma$ be an element of ω; let $\hat{\mathbf{n}}$ be the unit normal vector (outward drawn) at any point of ω. Then the curl of $\mathbf{v}$ is defined by

$$\text{curl } \mathbf{v} = \lim_{\delta \to 0} \frac{1}{\delta} \int_\omega \hat{\mathbf{n}} \times \mathbf{v} \, d\sigma.$$

(L.L.S.)

CURLEW. Aves, Charadriiformes. Shore birds (**Aves**) of several species with long legs, a moderately long neck, and a long curved beak. Related to the snipes. (A.W.L.)

CURRANT. Berry.

CURRENT CORRECTION ANGLE. The angle between the **heading** of a ship and the **course** of the ship relative to the earth is known as the current correction angle.

In sea **navigation** the actual motion of the water relative to the surface of the earth is known as current. The direction in which the water is moving is known as the set, and the speed of motion is called the drift. Three main types of currents are recognized by navigators: general ocean currents, tidal currents, and currents due to wind. General ocean currents are discussed in various publications of the Hydrographic Office and are plotted on the monthly Pilot Charts issued by that office. Tidal currents are predicted for any particular locality at any time by the U. S. Coast and Geodetic Survey in an annual publication known as Tide Tables. Tide tables for foreign shores are published by different governments. Currents due to winds are very difficult to determine with any exactness. Experience has shown that a wind, which has been blowing steadily for several hours, will produce a surface current which sets about 40° to the right of the direction toward which the wind is blowing in the northern hemisphere, and about 40° to the left in the southern hemisphere. The drift of wind currents is between 1 and 3% of the speed of the wind producing it. Many variables such as gustiness, steadiness of direction, etc., enter into the determination of wind currents and only long experience will give anything approaching accurate set and drift. In the article on **Dead Reckoning** a so-called "current" is discussed which is the "catch-all" for various errors in dead-reckoning navigation.

If a ship is to make good a specified course in a region where a current is known to exist, the so-called current correction angle should be determined to find the proper heading for the ship. The determination of this angle may be made either by graphical or computational methods. Either method is sufficiently accurate and the graphical method is more commonly used. However, the computational method is fully as rapid as the graphical and does not require the space and paraphernalia needed for constructing the vector triangle. The graphical method is practically identical with that discussed under **Wind Correction Angle.**

The simplicity of the computational method is indicated in the following case: A ship is operating, with cruising speed of 15 knots, in a region where a current is known to set 160° with drift of 3 knots. The navigating officer wishes to determine the proper heading for the ship in order that its actual motion relative to the surface of the earth shall be 270° (due west), and he also wishes to know the speed the ship will make good along this course. A free-hand sketch is helpful, but by no means necessary. Such a sketch is shown in Fig. 1.

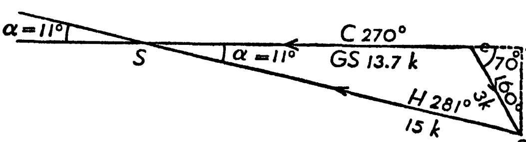


Fig. 1. Determining current correction angle.

The angle xec is known since the current sets 160° and the course is to be 270°. The side cs is known since the speed of the ship is 15 knots. Then by means of traverse tables, slide rule, or any form of three-place computing, we have:

70°	ec = 3.00 k	ex = 1.03 k	xc = 2.82 k
esc = 11°	cs = 15.00 k	xs = 14.73 k	xc = 2.82 k
		es = 13.7 k	

Hence we have the heading to be used given by 270° + 11° = 281° and the predicted speed along the course to be 13.7 knots. This work was done in about 2 minutes using nothing other than a pencil, pad of paper, and the traverse tables.

Any one of the **dead-reckoning computers,** designed for air navigation, may be used for solving problems of this sort. When using these, care must be taken to remember that they are designed for use with wind, and that wind direction is given as opposite to that in which the air is actually moving; while the set of the current is properly given as the direction in which the water is moving. (W.K.G.)

CURRENT DENSITY. This is the current in a conductor divided by the total area of the conductor. In this usage an ionized gas is considered a conductor. (L.R.Q.)

CURRENT TRANSFORMER. Transformer.

CURRENTS. Current Correction Angle.

CURURO. Tucotuco.

CURVATURE OF A PLANE CURVE. The curvature of a plane curve is defined by $\frac{d\phi}{ds}$, where ϕ is the inclination angle of the tangent to the curve and ds is the differential of arc length.

The reciprocal of the curvature is called the radius of curvature at the point.

If the equation of the curve in **rectangular coordinates** is $y = f(x)$, the radius of curvature is given by

$$R = \left[1 + \left(\frac{dy}{dx}\right)^2\right]^{3/2} \Big/ \frac{d^2y}{dx^2}.$$

If the equation of the curve is $r = f(\theta)$ in **polar coordinates**, the radius of curvature is given by

$$R = \frac{\left[r^2 + \left(\frac{dr}{d\theta}\right)^2\right]^{3/2}}{r^2 - r\frac{d^2r}{d\theta^2} + 2\left(\frac{dr}{d\theta}\right)^2}.$$

The center of curvature of a curve at a given point is a point on the normal on the concave side of the curve at a distance from the point of contact equal to the radius of curvature. The circle of curvature is a circle with center at the center of curvature and radius equal to the radius of curvature.

The coordinates of the center of curvature are, in rectangular coordinates:

$$\alpha = x - \frac{dy}{dx}\left[1 + \left(\frac{dy}{dx}\right)^2\right] \Big/ \frac{d^2y}{dx^2},$$

$$\beta = y + \left[1 + \left(\frac{dy}{dx}\right)^2\right] \Big/ \frac{d^2y}{dx^2}$$

(L.L.S.)

CURVE FITTING. **Empirical Equations.**

CURVE TRACING. **Locus of an Equation.**

CURVED BEAM. A curved beam is one which has a finite **radius of curvature** before and after the **bending loads** are applied. Theoretically the **flexure** formula is not applicable to curved beams because the unit **deformation** does not have a straight line variation over the depth of the beam due to the difference in the length of the various fibers between any two radial planes. Formulae for curved flexural members are given in texts on advanced strength of materials. Reliable values of extreme fiber stresses may be found by means of correction factors, applied to the flexure formula, which are also in these texts. The correction factor depends on the radius of curvature and the shape of the cross-section. However, a member must have a considerable amount of curvature before there is an appreciable difference between the stresses found by the straight beam (flexure) theory and the curved beam theory. Consequently a correction factor of 1 is frequently used when the radius of curvature is large.

The curved beam theory or a modification of this theory should be applied to the analysis of any curved flexural member of small radius of curvature even though the member cannot be classed as a beam. Hooks and chain links are typical examples. (C.W.C.)

CURVES, IN A PLANE. A plane curve may be represented by a single **equation** in two **variables** interpreted as **rectangular coordinates** or as **polar coordinates**. Instead of this, it is sometimes desirable to use two equations which express the coordinates of a variable point on the curve in terms of a third variable or parameter; these equations are then called the **parametric equations** of the curve.

To find the points of intersection of two curves whose equations are given: solve the given equations as a simultaneous system, arrange the real solutions in corresponding pairs, and these will be the coordinates of all the points of intersection. (L.L.S.)

CURVES, IN SPACE. Curves in space which do not lie in one plane are called skew curves, or twisted curves, or space curves. Such curves are frequently thought of as the intersection of two **surfaces**.

Space curves are generally represented by **parametric equations**, by which the rectangular coordinates x, y, z of any point of the curve are expressed as **functions** of a parameter.

The **cylinders** whose elements intersect a given curve and are parallel to one of the coordinates axes are called projecting cylinders of the curve.

If a given space curve is represented by parametric equations $x = f(t)$, $y = g(t)$, $z = h(t)$, the tangent line to the curve at a point $P_1(x_1, y_1, z_1)$ corresponding to $t = t_1$ has the equation

$$\frac{x - x_1}{f'(t_1)} = \frac{y - y_1}{g'(t_1)} = \frac{z - z_1}{h'(t_1)}.$$

The length of arc of this space curve is given by

$$s = \int_{t_0}^{t_1} [f'(t)^2 + g'(t)^2 + h'(t)^2]^{1/2} dt.$$

(L.L.S.)

CURVILINEAR CORRELATION. If two **variables** x and y are connected by a relationship which is not linear, then we say they are correlated curvilinearly. If $y' = b_0 + b_1x + b_2x^2$, then y' is determined by a quadratic function of x. However x' may be determined by y in a linear relationship, such as $x' = ay + b$, or by some curvilinear function. This theory may be generalized to any number of variables. It may also be used to determine the partial curvilinear correlation between x and y when any number of other variables are kept constant.

The coefficient of curvilinear correlation ρ is given by the relationship

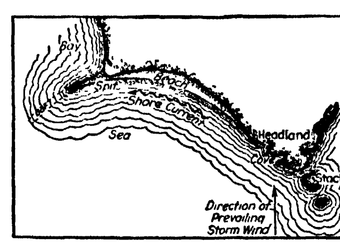
$$\rho^2 = 1 - \frac{\Sigma(y - y')^2}{\Sigma(y - \bar{y})^2}$$

where the y's are actual values and y' is determined by an equation $y' = f(x_1, x_2, \cdots, x_r)$, where the function f is not of first degree in all of the variables $x_1, x_2, \cdots, x_r$. Here $\Sigma(y - \bar{y})^2 = N\sigma_y^2$. The **regression** $y' = f(x_1, x_2, \cdots, x_r)$ is usually found by the method of **least squares**. The significance of a curvilinear coefficient of correlation is determined by the **analysis of variance**. Naturally the regression $y' = f(x_1, x_2, \cdots, x_r)$ is not restricted to polynomial functions. (L.A.A.)

CUSCUS. **Phalanger.**

CUSP. A tapering projection, such as the projections on the crown of a tooth or one of the pointed segments of a cardiac valve. (A.W.L.)

CUSPATE FORELAND. A coastal **headland** of triangular shape, with its apex seaward and its sides concave. (R.M.F.)



Sketch map illustrating erosion of a headland and development of shore current, beach, spit, bar, cove, and stacks, and cuspate foreland. (*After W. H. Hobbs.*)

CUTICLE. For the use of this term in botany, see **Leaf**. In zoology, cuticle is the outermost layer of the integument. (See **Integumentary System**.) As applied to the skin of the vertebrates this layer is composed of cells of ectodermal origin but in the invertebrates it indicates a noncellular layer secreted by the underlying cells. A cuticle of the latter type occurs in the parasitic flatworms, the rotifers, the roundworms and annelid worms,

and the arthropods. The cuticle of insects is usually called the cuticula. (A.W.L.)

CUTICULA. 1. The thickened plate at the free end of some epithelial cells. 2. The layer of scales covering a hair. 3. The noncellular layer covering the bodies of some invertebrates. Some entomologists call the outer and inner layers of the chitinous cuticula of insects the epidermis and dermis. The terms **epidermis, dermis, cuticle** and **cuticula** are loosely used. (A.W.L.)

CUT-LIP. Pisces, Teleostei. A small fresh-water fish, *Exoglossum maxillingua,* common from the St. Lawrence to Virginia. The nigger chub. (A.W.L.)

CUT-OFF. The term cut-off generally refers to a particular point in a cycle at which a mechanism cuts off some flow to or from the cycle. The steam engine cut-off is that % of stroke accomplished by the piston when the inlet valve closes and prevents more steam entering the cycle from the boiler. Up to the point of cut-off, the pressure of the steam against the piston is fairly constant, but when cut-off has occurred, the steam acts expansively with decreasing pressure. The cut-off of a Diesel cycle is the fraction of the stroke accomplished when supply of fuel oil to the cylinder is stopped. (F.T.M.)

CUT-OFF BIAS. This is the voltage which must be applied to the **grid** in order to stop the flow of anode or plate current in a vacuum **tube.** It is a valuable reference point in the discussion of vacuum tube characteristics as much of the tube behavior is determined by where the bias voltage is set with respect to the cut-off value. (See **Amplifiers.**) (L.R.Q.)

CUT-OFF FREQUENCY. While this term may be used to designate the frequency at which any electrical device ceases to function in the normal manner it is more commonly used in connection with electric wave **filters** and **wave guides.** When referring to filters it means the frequency at which the attenuation begins to increase sharply. In the ideal filter the attenuation would go to infinity at the cut-off frequency, but in a practical filter the rise in attenuation is not so abrupt and never reaches infinity, but does usually go to a very high value. When applied to a wave guide, the cut-off frequency is the lowest value of frequency which will be propagated down the guide without attenuation. This is determined by the dimensions of the guide. (L.R.Q.)

CUTS AND FILLS. Earthwork.

CUTTERS. Cutting tools are used for one or more of three purposes: material removal, dimensional or size accuracy, and surface refinement; in some instances one of these considerations is of primary importance and the others are, or must be, disregarded; in other cases all three must be considered. The work expended in metal cutting consists of tearing a small particle, termed a chip, from the metal, and overcoming the frictional resistance engendered by the chip passing over the surface of the tool as it curls or crumples.

Cutters may be roughly classified as single-point cutters and as multi-toothed cutters. The most familiar examples of single-point cutters are the inserted bits used for lathe, planer, and shaper tools; multi-toothed cutters are used for milling and broaching, although both drills and reamers fall into this classification. In metal and wood cutting, the cutting speed is the velocity, usually in in. or ft. per min., with which the cutter passes over the work. The *feed* is the relatively slow motion of either the cutting tool or the work in metal cutting. In drilling, the feed is generally stated as so many thousandths of an inch per revolution of the drill; in milling, the feed is generally given as so many inches of work movement per min. Single-point cutting tool nomenclature is illustrated in Fig. 1. This tool is similar to those used on planers and shapers, and moves

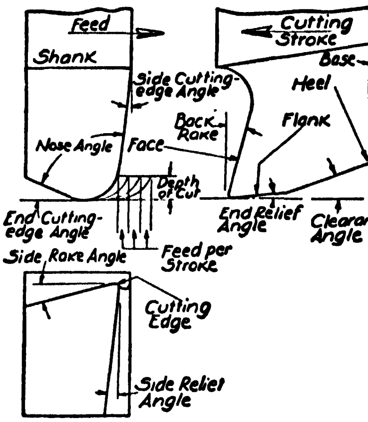


Fig. 1.

along a straight line and cuts on the forward stroke only. The cutting action takes place in two planes, and multiple rake and relief angles are provided.

Fig. 2 illustrates the action of and the difference between profile-type and form-type multi-toothed cutters. The profile-type cutter is sharpened by grinding along

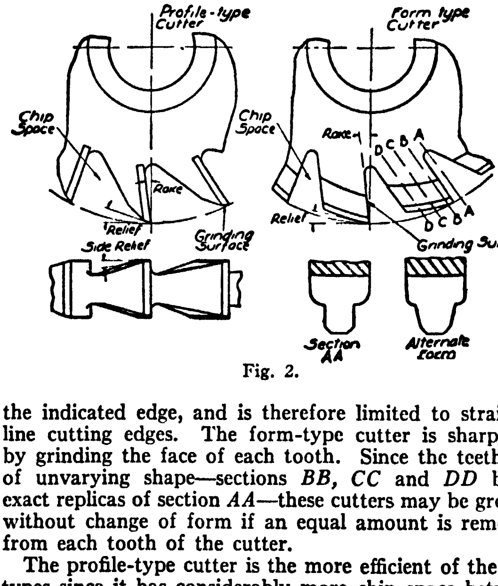

Fig. 2.

the indicated edge, and is therefore limited to straight-line cutting edges. The form-type cutter is sharpened by grinding the face of each tooth. Since the teeth are of unvarying shape—sections *BB, CC* and *DD* being exact replicas of section *AA*—these cutters may be ground without change of form if an equal amount is removed from each tooth of the cutter.

The profile-type cutter is the more efficient of the two types since it has considerably more chip space between the teeth. It is also possible to provide side relief for this type. The form-type cutter shown has no side relief since this would affect the tooth shape after grinding. Sometimes a change in the design of the work will permit an alteration in the cutter profile, as illustrated in the alternate form, thus permitting clearance or side relief.

If edge of the tooth moves perpendicular to the plane of the paper simultaneously with the direction indicated, the minute serrations of the cutting edge, on account of their saw-like action, aid in the removal of the chip. This principle is employed in rotating cutters by making the tooth edges helical instead of straight lines parallel to the cutter axis. Some of the shock of tooth contact is eliminated and a cleaner, smoother finish generally results. (H.C.H.)

CUTTING OUT. Forging.

CUTTING SPEED. Cutters.

CUTTING UP. Climb Cutting.

CUTTINGS. Propagation, Asexual Reproduction.

CUTTLEFISH. Mollusca, Cephalopoda. Mollusks, related to the squids but forming a separate family (Sepiidae). Used as food in the Oriental region. The shell is the cuttlebone of commerce and the ink sac secretes the pigment sepia. (See also **Invertebrate Paleontology.**) (A.W.L.)

CUTWORM. Insecta, Lepidoptera. **Larvae** of many species of **owlet moths** (Noctuidae). They hibernate when partly grown and in the spring often cut off young plants at the ground. In severe attacks they can be killed by poisoned baits. (A.W.L.)

CUVIERIAN ORGAN. A defensive organ found in some sea cucumbers (**Holothuroidea**). It is a modified part of the respiratory tree attached to the **cloaca**, and made up of tubes covered with sticky material. When irritated the animal contracts violently and ejects this structure through the ruptured wall of the cloaca. In the sea water the sticky material forms long adhesive threads which entangle the enemy. (A.W.L.)

CUXIO. Mammalia, Primates. A **monkey** of the Amazon valley, also called the black saki. (A.W.L.)

CW. Continuous Wave.

CYANAMIDES. Cyanamide ($NC \cdot NH_2$ or HN:C:NH) is a white solid, melting point 44° C., boiling point 140° C. at 20 mm. pressure, transformed at 150° C. into cyanuramide, tricyantriamide ($(NC \cdot NH_2)_3$). Cyanamide reacts (1) as a base with strong acids forming salts, (2) as an acid forming metallic salts, such as calcium cyanamide ($CaCN_2$). Cyanamide is formed (1) by reaction of cyanogen chloride ($CN \cdot Cl$) plus **ammonia** (ammonium chloride also formed), (2) by reaction of thiourea plus **lead** hydroxide (lead sulfide also formed).

When calcium cyanamide is boiled with water, dicyandiamide ($(NC \cdot NH_2)_2$), melting point 207° C. is formed (along with calcium hydroxide). Fusion of dicyandiamide with **sodium** carbonate plus **carbon** produces **sodium** cyanide plus **ammonia** (also some tricyantriamide). Diethylcyanamide ($(C_2H_5)_2N \cdot CN$) is a colorless liquid, boiling point 189° C. at 748 mm. pressure, and when hydrolyzed yields diethylamine ($(C_2H_5)_2NH$) plus ammonia plus carbon dioxide. Diphenylcyanamide ($C_6H_5N{:}C{:}NC_6H_5$) when hydrolzyed yields **aniline** plus carbon dioxide. Benzylcyanamide ($C_6H_5CH_2NH \cdot CN$) is a white solid, melting point 43° C. (R.K.S.)

CYANIC ACID AND CYANATES, AND RELATED COMPOUNDS, cyanic acid, isocyanic acid, fulminic acid, cyanuric acid, cyamelide, fulminuric acid. Cyanic acid (HCNO or HOCN) is a colorless, odorous liquid; soluble in water and in ether; volatile with decomposition when heated; passing at ordinary temperature into a mixture of cyanuric acid ($(HNCO)_3$) and cyamelide ($(CONH)_x$), white solid, which on vaporizing yields cyanic acid; when cyanic acid vapor is rapidly cooled in a freezing mixture, cyanic acid, liquid, unstable, is obtained, when the vapor is condensed above 105° C., cyanuric acid

($(HNCO)_3$ or )

is obtained. Cyamelide dissolves in **sulfuric acid** unchanged and addition of water causes precipitation of cyamelide; passes into cyanuric acid when warmed with concentrated sulfuric acid, finally into **carbon dioxide** plus **ammonia**; dissolves in **sodium** hydroxide solution forming sodium cyanate. Sodium cyanate is prepared by heating **sodium** cyanide and an oxide such as **lead** monoxide (PbO), trilead tetroxide (Pb_3O_4), or lead dioxide (PbO_2), addition of water and separation of the sodium cyanate solution from the lead oxide by filtration. Sodium cyanate solution upon boiling changes into sodium carbonate plus urea ($CO(NH_2)_2$).

Ammonium cyanate ($CNONH_4$), white solid, formed by reaction of sodium cyanate and **ammonium** sulfate solutions is transformed to **urea** upon being heated at 100° C. This reaction was carried out in 1828 by Wöhler, and is the first record of a so-called inorganic substance being transformed outside a living organism into a so-called organic substance. The following esters are known:

Methyl iso-cyanate (CH_3NCO), boiling point 44° C.
Ethyl cyanate (C_2H_5OCN), decomposes on heating.
Ethyl iso-cyanate (C_2H_5NCO), boiling point 60° C.
Phenyl iso-cyanate (C_6H_5NCO), boiling point 166° C.

Ethyl cyanurate 
Ethyl iso-cyanurate 
Fulminic acid (HONC) and the fulminates are violently explosive. Utilizing this property, mercuric fulminate ($Hg(ONC)_2 \cdot \frac{1}{2}H_2O$) is used as a detonator for other explosives. Mercury fulminate is made by the reaction of **ethyl alcohol** and **mercuric** nitrate in excess of **nitric acid**, from which insoluble mercuric fulminate separates. Silver fulminate ($Ag(ONC)$) is more explosive than mercuric fulminate, and is used in the manufacture of fire-crackers. Free fulminic acid may be obtained by reaction of potassium fulminate and excess of ether. It volatilizes with the ether upon distilling, and changes rapidly to metafulminic acid. Related to fulminic acid, is fulminuric acid ($(HONC)_3$ or $NO_2 \cdot CH(CN) \cdot CONH_2$). (R.K.S.)

CYANIDING. Carburizing.

CYANITE. Kyanite.

CYANOGEN. Cyanogen ($(CN)_2$) is a colorless gas of marked characteristic odor, very poisonous, density 1.8 (air equal to 1 0), melting point —28° C., boiling point —20° C., soluble, when passed into water at 0° C., cyanogen forms **hydrocyanic acid** plus **cyanic acid**, but at ordinary temperatures the reaction is complex. With **sodium** hydroxide solution, there is formed with cyanogen sodium cyanide plus sodium cyanate, with dilute sulfuric acid oxamic acid ($COOH \cdot CONH_2$), oxalic acid ($COOH \cdot COOH$). By reaction with tin and hydrochloric acid, cyanogen is reduced to ethylene diamine ($CH_2 \cdot NH_2 \cdot CH_2 \cdot NH_2$). Cyanogen reacts with hydrogen to form hydrocyanic acid, and with metals, e.g., zinc, copper, lead, mercury, silver, to form cyanides. Cyanogen, (1) when burned in air produces a violet flame forming **carbon dioxide** and **nitrogen** in the outer part and carbon monoxide and nitrogen in the inner part, (2) when exploded with **oxygen** produces carbon dioxide or carbon monoxide and nitrogen depending upon the ratio of oxygen to cyanogen (2 volumes oxygen plus 1 volume cyanogen yields 2 volumes carbon dioxide plus 1 volume nitrogen; 1 volume oxygen plus 1 volume cyanogen yields 2 volumes carbon monoxide plus 1 volume nitrogen). The flame spectrum contains characteristic bands in the blue and violet. By means of the electric spark, the electric **arc** or a red

hot tube, cyanogen is decomposed into carbon plus nitrogen. When heated at ordinary pressure at about 300° C., or under 300 atmospheres pressure at about 225° cyanogen is converted into paracyanogen, a brown powder, also formed when mercuric cyanide is heated. Cyanogen is prepared (1) by reaction of **sodium** cyanide and copper sulfate solutions, whereby one half the cyanogen is evolved as cyanogen gas and one half remains as cuprous cyanide. From the filtered cuprous cyanide, by treatment with ferric chloride solution, cyanogen is evolved with accompanying formation of ferrous chloride, (2) by heating mercuric cyanide solid, or a mixture of mercuric chloride and sodium cyanide solutions, mercury and mercurous, respectively, being formed, (3) by heating ammonium oxalate ($COONH_4 \cdot COONH_4$) with phophorus pentoxide, water being abstracted. Small amounts of cyanogen are present in blast furnace **gas** and raw coal gas. (R.K.S.)

CYANOSIS. A blue color of the skin and mucous membranes, most marked in the lips, nose, cheeks, ears, hands, and feet. It is due to the presence of abnormally large amounts of reduced haemoglobin (i.e., haemoglobin which has given up its oxygen to the tissues) in the blood. This occurs when there is a failure of aeration of the blood as it passes through the lungs so that insufficient oxygen is picked up by the red cells, or in circulatory failure and stosis of venous blood in peripheral vascular beds. It also occurs when there is abnormal communication between the venous and arterial sides of the circulation as in certain congenital malformations of the heart. Cyanosis is commonly seen in severe heart disease, particularly the congenital type, pneumonia, severe infections, asthma, and emphysema. It is also seen as a result of poisoning with gases, or drugs which interfere with repiration or the rate of absorption of oxygen by the blood. (D.M.H.)

CYANURIC ACID. **Cyanic Acid and Cyanates.**

CYBOTAXIS. A condition in which certain liquids, under **x-ray** examination, give evidence of structure resembling that of crystals. By passing a beam of x-rays through various alcohols and other organic liquids, G. W. Stewart and his collaborators have obtained one, two, or even three diffraction maxima or halos, somewhat like the diffraction rings produced by powdered crystals. (See **Crystal Structure.**) These suggest that molecules are temporarily arranged in rows, layers, or stacks like bricks in a pile and that they have one, two, or even three different dimensions or spacings, corresponding, in accordance with **Bragg's law,** to the different angles of diffraction observed.

A closely related property is exhibited by certain substances known as "liquid crystals," which appear to be intermediate between merely cybotactic liquids and true crystals. In these there appear to be large groups of molecules which, though able to move and turn about, retain their structural arrangement. Such mesomorphic substances manifest even some of the optical properties of crystals, which the former type do not. (L.D.W.)

CYCADLES. **Paleobotany.**

CYCADOFILICALES. **Paleobotany.**

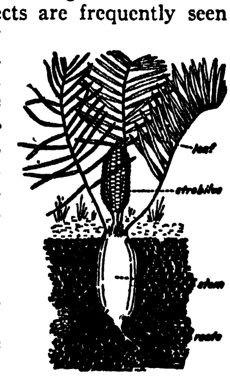
CYCADS. A group of **Gymnosperms** containing 9 genera and less than 100 species. They first appeared in late **Paleozoic** times, became a dominant group almost cosmopolitan in distribution in the **Mesozoic** period. Cycads are now limited to tropical or subtropical regions, often with a very restricted range. Sóme of the genera are found only in the New World, in Mexico and the West Indies; others occur only in the Old World, in Australia, Africa and various Islands of the Pacific Ocean. Bescause of their decorative habit they are frequently grown in cultivation in places outside their natural range. Many are grown as greenhouse plants in temperate regions.

The appearance of the plants is uniform in all genera. The stem is either columnar and rarely branched or

A cycad, *Dioon edule.* (*After Chamberlain.*)

underground, and much enlarged. Columnar stems are usually from 6–10′ tall, but some species grow much higher. These stems are generally thickly clothed in the persistent leaf-bases, which sometimes give an indication of the age of the plants. As determined by the number of leaf bases many are several hundred years old. Internally the stem contains a very large pith and a thick **cortex** with a narrow cylinder of wood between them. The leaves form a large crown at the top of the stem. They are pinnate except in one Australian genus, *Bowenia,* which has bipinnate leaves which are thick and leathery. The primary root is large and extends deep into the ground.

All Cycads are **dioecious** plants. The ovulate cones are usually very large. The different genera have cones which show a very distinct series, ranging from those of *Cycas revoluta* with loosely arranged leaf-like **sporophylls** to the compact cones of Zamia. The large **ovules,** or megasporangia, are covered by a single thick integument. The male cones are much smaller and always formed of compactly massed sporophylls, each of which bears many sporangia, or pollen sacs. The pollen grains are very numerous and light. Pollination is effected by wind, though insects are frequently seen on the male cones, and may play some part in the pollen transfer.



A cycad. Mature sporophyte of *Zamia* bearing a carpellate strobilus. (*Smith, Overton, Gilbert, Denniston, Bryan and Allen, Textbook of General Botany. Macmillan Co.*)

The pollen grains are caught in a sticky fluid, which covers the micropyle of the ovule. As this sticky substance dries, it shrinks, drawing the pollen grains down through the micropyle. Each pollen grain then puts out a pollen tube which digests its way through the mass of nucellar tissue which surrounds the **female gametophyte,** and reaches a small chamber which is formed at the micropylar end of the gametophyte and the **nucellus.** Meanwhile two sperm cells have been forming in the pollen tube. Each is very large and has a spiral band of cilia wound about its anterior end. Freed from the pollen tube, these sperm pass to the gametophyte, where union of one sperm with the egg occurs. Sperm and egg nucleus presently unite, and the egg is fertilized. The fertilized egg divides to form a mass of cells which is known as the proembryo. At the

base of this proembyro is a group of cells which becomes the true **embryo.** The embryo is pushed down into the tissue of the gametophyte by the elongation of a group of cells known as the suspensor. The mature seed of a Cycad has an outer fleshy coat which is variously colored. Inside this there is a hard stony layer which in turn surrounds another layer which is fleshy at first but soon becomes thin and dry. Within is the gametophyte which contains the embryo. Cycad seeds germinate as soon as they are mature.

Apart from their value as decorative plants or as curiosities, few products of importance are obtained from the Cycads. Their leathery leaves remain green for some time after removal from the plant. They are therefore often used on Palm Sunday and for funeral purposes. The seeds of many of them are edible, as is also the central portion of the stem of *Cycas* species. Cycads are sometimes confused with palms.

Cycads probably originated in very early times from some primitive ferns. Even today certain cycads closely resemble ferns. Cycads are "living fossils" which continue to exist in a very restricted range. (See **Paleobotany.**) (R.M.W.)

CYCLE. A series of changes executed in orderly sequence, by means of which a mechanism, a working substance, or a system is caused periodically to return to the same initial condition, constitutes a cycle. Many complicated machines or assemblages of machines work in definite cycles. An important form of cycle is the heat engine cycle, in which a series of thermodynamic changes in a working medium periodically return the system to the same thermodynamic level. This working medium may be a gas, as in the **Otto** and **Diesel** cycles, or a vapor, as in the steam cycle. See also **Carnot cycle,** for an example of a general ideal cycle. A vapor cycle is so named from the fact that it is conceived as using the same vapor over and over, passing it around what might be thought of as a closed loop of equipment, and subjecting it to various thermodynamic changes by means of which useful mechanical energy is produced from heat. The distinction between vapor and engine cycle should be recognized. An engine cycle considers only the changes occurring within an engine, but a vapor cycle involves, in addition, all changes in the vapor state from the point of leaving the engine until it is again ready to enter it. (See **Rankine Cycle, Regenerative Cycle, Reheat Cycle.**) (F.T.M.)

CYCLE OF EROSION. The work of rivers and streams is erosional, transportational and depositional. The erosional work of rivers and streams sculptures the surface of the earth into a variety of forms. So

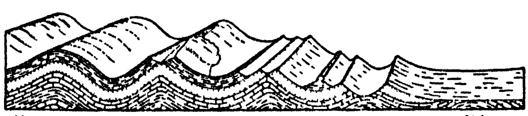


Diagram to illustrate successive stages in the normal cycle of erosion in a region of folded rocks. (*After G. H. Ashley.*)

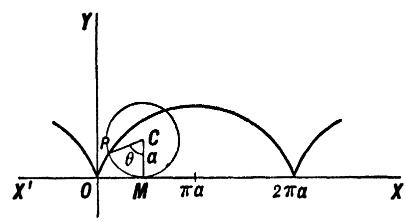
long as the land surface remains above sea level it is subject to such agents of denudation as wind, rivers and glaciers. The principal agent of denudation is running water (rivers and streams). The river **erosion** pattern of any region will depend upon (1) climate, (2) relative hardness and solubility of the formations, (3) structure, (4) the degree to which the erosive process has completed its work, with or without interruptions caused by **diastrophism.** The stream pattern of a region is not only indicative of the structural control, but also of the stage in its erosional history. The ideal complete cycle of erosion begins with uplift of a region with low altitude and ends with reduction of the uplifted region to a **peneplain.** (R.M.F.)

CYCLE OF STRESS. The **stress** variation on a particular plane through a specific point in a body which is subjected to a **repeated load** is called a cycle of stress. If the stress varies alternately between **tension and compression,** the variation is known as reversal of stress. The reversal is complete when the alternate stresses are equal in magnitude.

The algebraic difference between the maximum and minimum stresses of a cycle is the range of stress. The **endurance limit** depends on the range of stress. (C.W.C.)

CYCLOHEXANE. Cyclohexane, hexahydrobenzene, hexamethylene (C_6H_{12}) is a colorless liquid, boiling point 81° C. Cyclohexane is formed by reaction of **benzene and hydrogen** in the presence of a **catalyzer,** finely divided nickel, heated. Intermediate products of the hydrogenation are cyclohexadiene, dihydrobenzene, (C_6H_8) and cyclohexene, tetrahydrobenzene (C_6H_{10}). By regulated oxidation of cyclohexane, cyclohexene, or cyclohexadiene, benzene is formed. (R.K.S.)

CYCLOID. If a **circle** moving in a plane rolls along a straight line, a point on the circumference describes a curve called the cycloid.



Cycloid.

If the given line is the X-axis, and the origin is a point on this line at which the fixed point on the circle touches the X-axis, the **parametric equations** of the cycloid are

$$x = a(\theta - \sin\theta), \quad y = a(1 - \cos\theta),$$

where θ is the angle turned through by the radius of the circle and a is the radius of the circle. The rectangular equation of the cycloid is

$$x = a\cos^{-1}\left(1 - \frac{y}{a}\right) \pm \sqrt{2ay - y^2}$$

which is not ordinarily convenient for use.

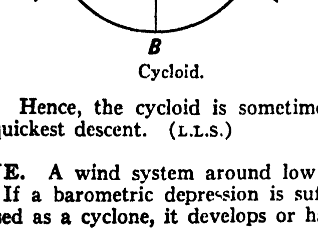
The area of one arch of the cycloid is $3\pi a^2$ and the length of one arch of the cycloid is $8a$, where a is the radius of the rolling circle.

The teeth of gears are often cut with faces which are arcs of cycloids, so that there is rolling contact when the gears are in mesh.

The inverted arch of a cycloid has the following two mechanical properties:

1. If two particles sliding without friction start from any two points of the curve at the same time, they will reach the lowest point at the same instant.

2. A particle sliding without friction will travel from O to B in less time than along any other curve connecting



Cycloid.

O and B. Hence, the cycloid is sometimes called the curve of quickest descent. (L.L.S.)

CYCLONE. A wind system around low atmospheric pressure. If a barometric depression is sufficiently low to be classed as a cyclone, it develops or has associated

with it winds which flow around its center counterclockwise in the northern hemisphere and clockwise in the southern hemisphere. The intensity of a cyclone depends on the pressure gradient between the system's center and periphery, and on the characteristics of the air masses involved. Cyclones are divided into two groups.

1. Tropical cyclones are vortices with indefinite or short-lived frontal structures which occur over the tropical and subtropical regions, particularly over the western half of the Atlantic and Pacific and over the Indian Ocean. They are known as hurricanes, typhoons, and baguios.

2. Extra-tropical, or wave cyclones are composed during development, youth and maturity of definite parts including warm and cold sectors and warm and cold fronts, but beyond maturity approach vortex structure. Nearly all the storms of the temperate zone are wave cyclones. (See **Wave Cyclones; Fronts; Winds.**) (P.E.K.)

CYCLOPROPANE. **Anaesthesia; Hydrocarbons.**

CYCLOSTOMATA. The round-mouthed **eels, hag fishes** and **lampreys.** A class of the phylum **Chordata** made up of marine and fresh-water species resembling slender fishes in form but without hinged jaws.

The principal characters of the class are: 1. The **notochord** is persistent. 2. Cartilaginous neural arches indicate the development of a vertebral column. 3. There are no paired fins. 4. The mouth is a funnel-shaped depression with chitinous (see **Chitin**) teeth. 5. External gill openings are separate.

The two principal subdivisions of the class are listed both as subclasses and as orders in modern classifications.

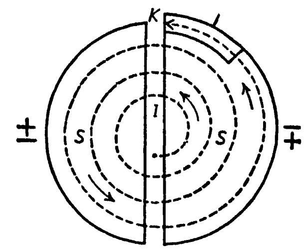
Subclass Myxinoidea (Hyperotreta). The **hag fishes.** Marine species with a poorly developed oral depression. Gill openings far behind head.

Subclass Petromyzontia (Hyperoartia). **Lampreys.** Marine and fresh-water species with a well-developed oral funnel. Gill openings immediately behind head. (A.W.L.)

CYCLOSTROPHIC WIND. Winds which blow as a result of a pressure gradient and centrifugal force, but in the absence of Coriolis Force. They are, of necessity, cyclonic and restricted to equatorial zones which is the only place Coriolis Force is zero, or nearly zero. The cyclostrophic component of a wind is the difference between the gradient and the geostrophic winds. Hurricanes are largely cyclostrophic winds until they travel north or south sufficiently to be affected by Coriolis Force. (P.E.K.)

CYCLOTRON. This name has been given to the magnetic resonance accelerator, a device developed in 1931 by Lawrence and Livingston for imparting very great velocities to heavier **nuclear particles** without the necessity of excessive voltages. The electrified particles (such as protons or helium nuclei) are released in the region between two large, flat, hollow, semicircular segments S, S, of thin metal placed with their diametric edges closely parallel, as if one had cut a pill-box in two along a diameter and slightly separated the halves. (See figure.) These segments, called "dees," are given a high-frequency alternating potential difference, producing a rapidly oscillating field in the space *I* between, them, and thus causing a free particle to be pulled first one way and then the other. A strong, uniform magnetic field is applied perpendicular to the plane of the segments. The result is that, as a particle darts into one of the segments, it follows a semicircular path of radius proportional to the speed (as in a **mass spectrograph**) and re-enters the interspace *I* on the other side of the center. The time required for this semicircular journey depends only upon the intensity of the magnetic field, and does not change with the velocity of the particle and the radius of its path. Now if the field is adjusted so that this time equals ½ the electric oscillation period, the particle will always emerge into an electric field so directed as to pull it in the direction it is already going, and in this way its speed increases at each crossing of the interspace. Thus, starting near the center, the particle spirals outward and speed increasing each half-turn, until it finally escapes into a receptacle *K* near the outer edge. The apparatus must, of course, be in a vacuum.

The first cyclotron imparted over 1,200,000 **electron volts** of energy to protons with an applied voltage of only 4000 volts; more recent installations have produced



Diagrammatic plan of cyclotron. Ions released in interspace. *I*, traverse hollow sectors S in semi-circles, and are finally utilized or allowed to escape at *K*.

5,000,000 electron volts. Such fast-moving particles are of great value in nuclear research, being used to bombard the atoms of substances placed in the receptacle *K*. An apparatus which serves a similar purpose with electrons (to which the cyclotron is not well adapted) has been developed by Kerst and Serber (1941) and given the name "betatron." (L.D.W.)

CYDIPPIDA. An order of **Ctenophora.**

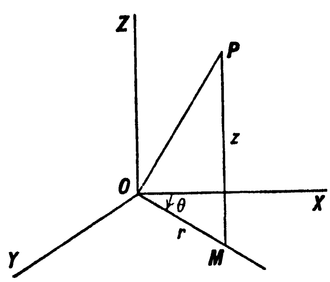
CYGNUS. (The swan.) (Map, page 380.) Cygnus is one of the most striking and interesting **constellations** of the northern sky. It represents a swan flying with outstretched wings and legs trailing out behind. It is also frequently referred to as the northern cross. Lying, as it does, in one of the most impressive portions of the northern **milky way,** the constellation contains many interesting objects. The brightest star (alpha Cygni) known as Deneb, is one of the most distant of all of the bright stars; its intrinsic brightness being about 1000 times that of the sun. Beta Cygni is one of the most striking of all of the **double stars,** both components being bright, one blue and the other orange, and easily separated by a small telescope. No physical connection has been determined between the components and it probably is not a true **binary.** Another interesting member of this constellation is the relatively faint star, marked 61 on large star maps. This is the first star whose distance was measured in 1838 by the astronomer Bessel. Bessel's determination of the **stellar parallax** of this object opened a field of astronomic research which has done much to solve many of the problems of general cosmogony. (W.K.G.)

CYLINDER. A cylindrical surface is a **surface** generated by a straight line which moves parallel to itself and intersects a given **curve.** A cylinder is a solid bounded by a cylindrical surface and two parallel planes which cut all the elements of the surface. The volume of a cylinder is equal to the area of its base times its altitude; for a right circular cylinder of altitude h and radius of base r, the volume is $V = \pi r^2 h$. The lateral area of a cylinder is equal to the perimeter of a right section times its lateral edge; for a right circular cylinder of altitude h and radius of base r, the lateral area is $A = 2\pi rh$. The **locus of an equation in rectangular coordinates** of higher degree than the first in which one variable is lack-

ing is a cylindrical surface whose elements are parallel to the axis along which that variable is measured.

Because it is comparatively easy to form, by usual means of manufacture, and because its shape is very well adapted to the resisting of internal bursting pressure, the cylinder is a very common engineering shape. While, of course, anything of cylindrical shape might truly be called a cylinder, it is customary to apply the term to that part which, in conjunction with a closely fitting internal **piston** will provide an enclosed space the volume of which may be varied by motion of the piston. Expansion of volume of a working medium is the basis of all commercially employed power cycles, and the cylinder and piston have an important place in this field. Engine-type prime movers have cylinders and pistons, and the widespread employment of the **internal combustion engine** for personal transportation in the United States has made of the cylinder a part familiar to many persons. The cylinder of an internal combustion engine or an air compressor needs to be cooled while the machine is in operation in order to keep the interior wall temperature low enough so that a lubricating oil film may be maintained between the piston and the cylinder. Air cooling and water cooling are resorted to for this purpose, the former for finned, the latter for jacketed, cylinders. Water **pumps** and steam **engines**, by the nature and temperature of the working substance enclosed in their cylinders, do not need to be cooled. The cylinder should be made of some hard metal having good wearing characteristics and be machined and honed to a bright finish and exact size. Nickel, cast iron, and steel have been extensively used for internal combustion engine cylinders. Cylinders may be made of brass, bronze, or other special materials when the working medium is corrosive to iron or steel. (L.L.S., F.T.M.)

CYLINDRICAL COORDINATES. The cylindrical coordinates of a point in space are three numbers which determine the position of the point; they are useful in mathematical problems dealing with cylinders and cones.



Cylindrical coordinates.

Let P be any point in space, and referred to a system of **rectangular coordinate** axes. Let M be the projection of P on the XY-plane; let $r = OM$, $\theta = \angle XOM$ be **polar coordinates** of point M in the XY-plane, and let $z = MP$ be the third rectangular coordinate of P.

The cylindrical coordinates of point P are the three numbers r, θ, z.

The relation between rectangular and cylindrical coordinates of a point in space are given by

$$x = r\cos\theta, \quad y = r\sin\theta, \quad z = z.$$

(L.L.S.)

CYLINDRICAL HARMONICS. Bessel Functions.

CYME. Flower.

CYMOPHANE. Chrysoberyl.

CYPRESS. Conifers.

CYST. 1. A capsule containing semi-solid or fluid material which may be under pressure. The contents of a cyst may be retained normal secretions, e.g., the sebaceous cyst which contains the products of a plugged sebaceous gland; or they may represent a fluid collection associated with a parasitic infection, e.g., echinococcus cysts of the brain, liver or other organs. Many tumors undergo cystic degeneration, especially carcinomas of the ovary, breast and uterus. Benign cysts occur in the ovary, spleen, lungs, kidney and liver where they are often congenital. Other congenital cysts result from fetal malformations and failures of development, such as the several cysts which occur in the neck. 2. The resting form of an organism in a protective covering. Significant examples in medicine are the cysts of *Endamoeba histolytica* which are found in the stools of patients with **amoebic dysentery**, and the encysted larva of **Trichinella spiralis** which can be demonstrated in the muscles of individuals who have had **trichiniasis.** 3. The vesicular portion of the bladder-worm stage of a **tapeworm.** (D.M.H., A.W.L.)

CYSTICERCOID. A small **bladder worm** in which the scolex fills the interior. (A.W.L.)

CYSTICERCUS. Bladder Worm.

CYSTINE. Aldehydes, Ketones, and Related Compounds.

CYSTITIS. Infection of the urinary bladder. This may be acute or chronic, and may be caused by a variety of bacteria, the most common ones being *B. coli* and allied organisms. **Streptococci** and **staphylococci** are next in frequency; specific infections with the tubercle bacillus and the gonococcus also occur.

Cystitis may be an ascending infection through the **urethra,** or it may be secondary to infection higher in the urinary tract in the **ureters** or **kidneys.** Obstructive and traumatic factors may play a role.

The symptoms of cystitis are frequency and urgency of urination with burning and pain. Treatment of *B. coli* and coccal infections with **sulfonamides** usually results in prompt cure. (D.M.H.)

CYSTOIDS (Cystids). Invertebrate Paleontology.

CYSTOSCOPY. Examination of the inner surface of the urinary bladder by means of a cystoscope, an instrument which is passed through the **urethra** into the bladder, where, by use of lights and lenses, a view of the inner bladder wall may be obtained. (D.M.H.)

CYTOGENIC GLAND. An organ which produces and discharges **cells,** such as the reproductive glands. (A.W.L.)

CYTOPLASM. Cell.

CYTOSOME. Cell.

D

DAB. Pices, Teleostei. *Limanda.* British and American flat fishes (**Pisces**) of several species. Edible. (A.W.L.)

DABCHICK. Aves, Colymbiformes. The little **grebe**, *Podicipes fluviatilis,* an aquatic bird of the Old World, and the pied-billed grebe, *Podilymbus podiceps,* of the New World. (A.W.L.)

DACE. Pisces, Teleostei. Various fishes (**Pisces**) of the family Cyprinidae, which contains also the **minnows** and **carps.** Among the North American species are a minnow called the red-bellied dace, *Chrosomus erythrogaster,* the common **shiner, redfin,** or dace, *Luxilus cornutus,* and two other small fishes, the long-nosed dace, *Rhinichthys cataractae,* and the black-nosed dace, *R. atronasus.* (A.W.L.)

DACITE. The name of a somewhat variable group of extrusive **igneous** rocks similar to the **rhyolites** but richer in **plagioclase feldspar.** Typical dacites are **felsitic** to **porphyritic** in texture. Dacites are the extrusive equivalents of the quartz-rich varieties of diorites and are sometimes classified as quartz-bearing **andesites.** The porphyritic types usually occur toward the center of the thicker dacite flows, **dikes** and **sills,** as well as the marginal zones of **laccoliths.** Dacites are common in the Cordilleran province of North, Central and South America. The term, dacite, was proposed by G. Stache of Austria for lavas in the old Roman province of Dacia. (R.M.F.)

DACTYLOPODITE. **Biramous Appendage.**

DACTYLOZOOID. A form of **polyp** found in colonial **Hydrozoa** which captures prey and brings it to the mouth. (A.W.L.)

DADO. A groove of rectangular cross-section, used in woodworking, cut across the grain. A plough cut is similar to a dado cut, but is cut with the grain. A rabbet is a dado cut at the edge of a piece of work. Mortise and tenon joints consist of two pieces—one piece has a slot or hole, called the mortise, cut in it, in which a corresponding piece, called the tenon, fits. A blind mortise and tenon joint is one in which the mortise hole is not cut through. Mortise and tenon joints may be of square, rectangular, or circular section. Other varieties of wood joints include crosslap joints, dovetails, etc. (H.C.H.)

DADDY LONGLEGS. **Arachnida.**

DAGUERREOTYPE. The first practical process of photography was invented by Louis J. M. Daguerre of Paris in 1837, although the details of the process were not published until 1839. The process was used chiefly for portraiture and became obsolete within a few years after the introduction of the wet collodion process in 1851. Although the first commercially successful process, modern photography is based on the negative-positive methods introduced the same year by William H. Fox-Talbot of England. In the daguerreotype process a light-sensitive layer of silver iodide is formed on a silver plate by contact with iodine. After exposure in the camera, a positive image is produced when the image is exposed to mercury and heated. The mercury, by attaching itself to the unexposed portions, forms a positive image. The silver iodide remaining was removed at first with a solution of sodium chloride (salt) which was soon replaced, however, with sodium thiosulfate (hypo), the properties of which had been discovered by Herschel in 1819. The daguerreotype image so produced is very weak. In 1840 Fizeau described a process of toning with gold which greatly increased the strength of the image and was generally adopted.

At first, from 5 to 10 minutes' exposure was required on open landscapes and street scenes. The invention of a fast, large-aperture portrait lens by Petzval in 1841 and the discovery by Goddard in London (1840) of the superior sensitivity of silver bromide reduced the time of exposure to a few seconds. (C.B.N.)

DAKIN'S SOLUTION. An antiseptic aqueous solution of **sodium** hypochlorite, modified with **sodium** bicarbonate, used in the irrigation of infected wounds. The solution was introduced during World War I by Henry Dakin, a New York chemist. (R.S.M.)

D'ALEMBERT'S PRINCIPLE. The principle, first pointed out by d'Alembert in 1742, that **Newton's** third law (see **Newton's Laws of Dynamics**) holds for forces acting upon bodies entirely free to move as well as upon fixed bodies in stationary equilibrium. In the former case the "reactions" concerned are due solely to inertia. Thus, in the act of throwing a ball, one pushes upon the ball with a certain force, and the inertia of the ball causes it to push back on the hand with an equal force. The condition of the system during such a process is said to be one of kinetic equilibrium. From this point of view, obviously, any system of bodies must always be in equilibrium, either kinetic or static. (L.D.W.)

DALTON'S LAW. The well-known law of partial pressures in mixed gases and vapors. If several gases not reacting chemically upon each other are introduced into the same container, the pressure of the resulting mixture is equal to the sum of the pressures which would be observed if each gas were separately enclosed in that container. We may, for example, regard the **atmospheric** pressure as the sum of a nitrogen pressure, an oxygen pressure, an argon pressure, a carbon dioxide pressure, a water-vapor pressure, etc. The same principle holds for mixtures of the saturated vapors of two or more liquids evaporating in the same closed space, provided one liquid does not dissolve the vapor from the other (as water dissolves ammonia). Like other gas laws, this law is approximately valid only within limits. (L.D.W.)

DAM. The primary function of the dam is to fill the gap in the natural reservoir line left by the stream channel. The most desirable sites are usually those where this gap becomes a minimum for the required storage capacity. Topographical and geological conditions at the site may be expected, in most cases, to dictate the choice of the type of dam. The best economic arrangement is often a composite structure such as a masonry dam flanked by earth embankments. The dam further serves to divert the water to the intake works.

Dams may be classified as follows:

1. Timber dams.
2. Rock-fill dams.

3. Earth dams.
   Plain.
   Core wall.
   Hydraulic fill.
4. Masonry dams.
   Gravity, solid and hollow.
   Arch, single and multiple.

Timber Dams.—The timber dam is rarely used because of its short life and the limitation in height to which it may be carried. It is conceivable that in a location where timber is plentiful and cement costly and difficult to transport, and where only a submerged diversion dam is contemplated, the timber dam would be the most economical to construct, even taking due account of its lack of permanence.

Rock-Fill Dams.—The rock-fill dam is an embankment of loose rock with either a water-tight upstream face of concrete slabs or timber, or a water-tight core. Where suitable rock is at hand in plentiful amount, a minimum of transportation of materials can be realized with this type of dam. Like the earth embankment, it resists damage from earthquake shock very effectively.

Earth Dams.—The earth dam is constructed as (1) a simple homogeneous embankment of well-compacted earth, (2) the same, but with a water-tight core or an upstream face pavement, (3) a **hydraulic fill** in which hydraulic segregation is relied upon to produce a water-tight core.

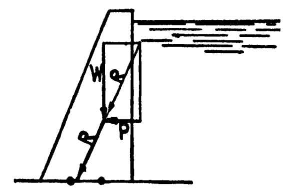
Earth dams.

Masonry Dams.—Masonry dams are of either the gravity or arch type. Stability is secured in the gravity dam by making it of such a shape and size that it will resist overturning, sliding and crushing at the toe. In the arch dam stability is obtained by a combination of arch and gravity action. If the upstream face is vertical the entire weight of the dam must be carried to the foundation by gravity while the distribution of the normal **hydrostatic** pressure between vertical cantilever and arch action will depend upon the stiffness of the dam in a vertical and horizontal direction. When the upstream face is sloped the distribution is more complicated. The normal component of the weight of the arch ring may be taken by arch action while the normal hydrostatic pressure will be distributed as explained above. Hence, for the gravity type, good impervious foundations are essential, but, for the arch type, firm, reliable support at the abutments (either buttress or canyon side wall) is more important. The most desirable site for an arch dam is a narrow canyon with steep side walls of sound rock. When situated on a suitable site, the gravity dam inspires more confidence in the layman than any other type. It has mass that lends an atmosphere of permanence, stability, and safety. When built upon a carefully explored foundation with stresses calculated from completely evaluated loads, the gravity dam probably represents the art of dam building at its highest point of development. This is an attribute of no mean significance because, due to flood disasters and their tremendous potentialities, fear of flood is a keenly developed human instinct. This factor has led to the adoption of the gravity section in some instances where an arch dam would have been the more economical construction.

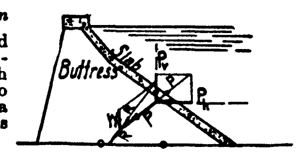
(a) *The Solid Gravity Dam*

W is large enough, with respect to P, to incline R sufficiently to fall within the middle third.



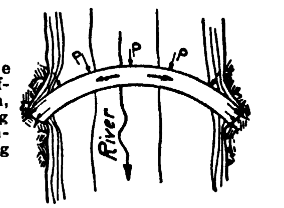
(b) *The Hollow Gravity Dam*

The slab is inclined enough to produce a vertical water pressure P_v which inclines P sufficiently to overcome the effect of a small W, so that R falls within the middle third.



(c) *The Arch Dam*

Water pressure on the upstream face has the effect of shortening the dam, thereby creating resisting compressive stresses within the dam and tightening it against the abutments



Comparison of stabilizing forces in dams.

Gravity dams are classified as *solid* or *hollow*. The solid type is the more widely used of the two, although the hollow dam is frequently the more economical to construct. Most forms of hollow dams have been patented by Ambursen and others. The gravity dams can also be classified as *overflow* and *non-overflow*. If the dam is to serve as a spillway section, its downstream face is ordinariiy made an ogee curve with the curvature such that there will be no tendency of the water to leave the surface of the concrete, even with maximum water elevation at the crest.

Two types of single-arch dams are in use; namely, the constant angle and the constant radius dam. The constant radius type employs the same face radius at all elevations of the dam, which means that as the channel grows narrower, as at the bottom, the central angle subtended by the face of the dam becomes smaller. In a constant angle type of dam, this subtended angle is kept a constant and the variation in distance from abutment to abutment at various levels taken care of by varying the radii. The safety of an arch dam is dependent on the strength of the side wall abutments, hence the arch should not only be well seated on the side walls, but the character of the rock in bearing be carefully inspected to determine its ability to take the enormous thrust that will be set up as the water rises. The multiple-arch dam consists of a number of single-arch dams with concrete buttresses as the supporting abutments. The multiple-arch dam does not require as many buttresses as the hollow gravity type, so is very economically constructed. It requires good rock foundation because the buttress loads are heavy. (F.T.M.)

DAMMAR. **Resins.**

DAMPED WAVES. This is ordinarily used to designate electric waves which decrease in amplitude with time. In any oscillatory circuit which contains resistance (and all practical ones will) the oscillations will be dissipated in resistance losses and the amplitude of the oscillations will gradually decrease unless energy is continually added to the circuit. When energy is added to overcome this dissipation and maintain the amplitude constant, continuous waves result. A **condenser** discharging through an **inductance** will give rise to damped waves and this was the basis of the old spark radio transmitters where the spark gap initiated the discharge and the oscillations continued until all the energy had been dissipated. Since these waves are not as effective for radio transmission as the **continuous waves** and since they give rise to spurious frequencies they are no longer used for this purpose. (L.R.Q.)

DAMPER WINDINGS. These are windings, also called amortisseur windings, placed in the pole faces of synchronous **motors** and generators to counteract the tendency these machines have to hunt or oscillate about the equilibrium position. When the synchronous machine is rotating at synchronous speed and is not oscillating about this speed as a mean value, the a-c field set up by the armature is fixed with respect to the rotating pole faces. (See **Motors.**) There is, then, no change of magnetic flux across the windings in the pole face. However, if the machine hunts it oscillates about the synchronous speed so the windings in the pole faces are swept back and forth across the armature flux. These windings are actually bars placed in the pole faces and shorted by an end connection so the changing flux induces a voltage, resulting in a circulating current which reacts to damp out the hunting. In synchronous motors and condensers this winding is used as a squirrel-cage winding to start the machine as an induction motor. (L.R.Q.)

DAMPING. This term usually refers to the checking of a motion due to friction or similar cause. It is of especial significance in connection with the diminishing amplitude of an oscillation, as that of a pendulum swinging in the air or that of the electricity vibrating in an oscillating circuit. Unless energy is supplied during each cycle, the amplitude of such a vibrator falls off at each successive oscillation by an amount commonly expressed in terms of the decrement or damping factor, which is the ratio of any one amplitude to that next succeeding it in the same sense or direction. In so-called logarithmic damping, this decrement is constant; in an oscillating electric circuit, its value is an exponential e^{δ}, in which δ, the logarithmic decrement, is a constant depending upon the effective resistance, inductance, and capacitance of the circuit. (See **Electric Oscillations and Waves.**)

An important instance of damping is found in the reading of an oscillating index, like a balance pointer, on a scale. If one may assume that the amplitude falls off by equal amounts at each swing ("linear" damping), in order to find the equilibrium position one has only to average an even number of readings at one extreme and an odd number at the other, and then find the mean of the two averages.

When metals are stressed repeatedly within the elastic range they dissipate energy into heat because of "internal friction" or the "mechanical hysteresis effect." This characteristic is also known as "damping capacity" and may be expressed as the amount of work dissipated into heat by a unit volume of the material during a completely reversed cycle of stress. (See **Hysteresis.**)

The damping capacity of metals and alloys can be determined by the torsion pendulum method and by other methods in which the metal specimen is vibrated and the rate of damping-out of the vibrations observed. **Cast iron** has been found to have a high damping capacity, a characteristic which is considered desirable in lathe beds and castings for other machine tools where rigidity is required. Materials with high damping capacity are also believed to be less sensitive to fracture at notches and other surface irregularities when subjected to cyclic or repeated stresses. For a given material, increase in hardness by **heat treatment** or **cold working** would normally be expected to reduce the damping capacity, however many exceptions have been noted. (L.D.W., R.H.H.)

DAMPING-OFF. This is a disease of plants, especially young seedlings, caused by several species of **fungi**, one of which is *Pythium*. This fungus has a slender, branching, non-septate **mycelium** containing many minute nuclei. At the apex of a branch of this mycelium an **oögonium** is formed. This is a spherical body containing many nuclei. One of these nuclei stays at the center of the oögonium; the others migrate to the periphery. From the tip of another branch of the mycelium a multinucleate **antheridium** is formed. The antheridium grows to the surface of the oögonium, and develops a slender conjugation tube which penetrates the oögonial wall. Through this tube a nucleus enters the oögonium and fuses with the central nucleus of that body. The latter now becomes an **oöspore**, a thick-walled object which may remain for a long time without change. Eventually it puts out a germ tube, at the tip of which a **zoösporangium** forms. The protoplasm within the zoösporangium becomes multinucleate. This protoplasm then escapes from the zoösporangium, but is retained for some time within a thin membrane. In this membrane the protoplasm breaks up into minute kidney-shaped zoöspores, each of which has two laterally attached **cilia**. The zoöspores escape from the sporangium and swim about actively for a time. Each then encysts, that is, secretes about itself a thick wall. After a time the encysted zoöspore forms a short germ tube from which a single zoöspore escapes and swims about. This process of encysting and emerging as a zoöspore may be repeated several times.

In those species which can parasitize plants, a zoöspore comes in contact with a root hair. It passes into the **protoplast** of this root hair and then enters the cortical tissues of the root. There it grows through the tissues, completely destroying them and quickly causing the death of the plant. Because of the extremely rapid growth of the parasite, once it enters the tissues of the host, the latter dies very suddenly, the top dropping over and collapsing. Often whole flats of seedlings succumb in a very few hours after the fungus appears. Adequate moisture is necessary for the fungus to grow, abundant moisture favors it greatly, and insufficient moisture retards it. Control of this pest is therefore largely a matter of reducing the moisture available as much as possible. The danger of losing valuable seedlings by damping-off may be prevented by steam sterilization of the soil and chemical sterilization of the surfaces of seeds. (R.M.W., B.S.M.)

DAMSEL FLY. Odonata.

DANBURITE. The mineral danburite, $CaB_2(SiO_4)_2$, **calcium-boron silicate**, crystallizes in the **orthorhombic** system in prismatic forms somewhat resembling the mineral topaz. Its fracture is subconchoidal; brittle; hardness, 7–7?; specific gravity, 2.97–3.02; color, colorless, yellowish-white, yellow, dark wine yellow and brownish-yellow; luster, vitreous to greasy; translucent to transparent. It is found at Danbury, Connecticut, from whence its name was derived, Saint Lawrence County, New York, Switzerland, Japan and Madagascar. (E.S.C.S.)

DANDELION. *Taraxacum.* **Composite Family.**

DANDRUFF. Seborrhea.

DARLINGTONIA. Insectivorous Plants.

D'ARSONVAL. Instruments, Electrical.

DART SAC. A structure associated with the female genital duct of **snails.** It secretes a calcareous dart which is shot by muscular contraction into the body of another snail when the two approach each other prior to mating. (A.W.L.)

DARTER. 1. Pisces, Teleostei. Small fishes (**Pisces**) constituting the family Etheostomidae. They have a small swim bladder or none, hence they rest on the bottom when not in active motion. 2. Aves, Pelecaniformes. *Anhinga.* Long-necked diving birds (**Aves**) with long sharp beaks, found in all continents. Also known as snake birds, anhingas and snake necks, and certain species as the wryneck and water turkey. They resemble the cormorants. (A.W.L.)

DASH-POT. The dash-pot is a device for effecting a quick, jerking, mechanical motion. In its usual form it consists of a **cylinder** with a closely fitting **piston.** As there are no inlet ports on the cylinder, motion of the piston increasing the volume creates a **vacuum** in the cylinder. This vacuum, amounting to 10–13 lbs. pull on every sq. in. on the piston, will, in the case of a large piston, produce a pull on the piston rod sufficient to overcome considerable resistance, and literally dash the piston back to the point from which the vacuum was started. Although a spring could be considered potentially capable of performing the same service as a dash-pot, it is inferior for some jobs. There is always a certain amount of resilience or springiness not possessed by the dash-pot, a tendency for fatigue of the metal, and of stiffness when used for large forces. (F.T.M)

DASYURE. Mammalia, Marsupialia. *Dasyurus.* Arboreal pouched animals (**Marsupialia**) of the Australian region. They are long-tailed forms with short legs resembling the civets and are carnivorous. The dasyure family includes also the thylacine or Tasmanian wolf, the Tasmanian devil, the phascologales, the pouched mouse, and the banded anteater. All are carnivorous or insect-eating. (A.W.L.)

DATE. *Phoenix dactylifera.* **Palm.**

DATE LINE. International Date Line.

DATOLITE. Datolite, **calcium boroxy silicate,** $Ca(BOH)SiO_4$, occurs in **monoclinic** crystals of varied habit, mostly short stout prisms, but often in highly modified forms. Datolite reveals no cleavage, its fracture is conchoidal to uneven; brittle; hardness, 5–5.5; specific gravity, 2.9–3.0; luster, vitreous to dull; color, white to gray or may be greenish, yellowish, or brownish. It has a white streak and is transparent to translucent usually, but has been observed opaque. Datolite is a secondary mineral being found in veins and cavities associated with **zeolites** and **calcite,** particularly in the **basic igneous** rocks. It has been found in the Harz Mountains, Germany; in the Trentino district, Italy; in Norway and Tasmania. In the United States it has been found in the Triassic **traps** of the Connecticut River Valley in Massachusetts and Connecticut, and from similar rocks in New Jersey. In Michigan Datolite has been found associated with the copper-bearing rocks of Keweenaw County. This mineral derives its name from the Greek word meaning to divide, in reference to the granular structures of some of the massive varieties. (E.S.C.S.)

DATUM. Earthwork.

DAVISSON-GERMER EXPERIMENT. In 1927, Davisson and Germer conducted a research, the results of which furnished a remarkable confirmation of the basic postulate of **wave mechanics.** De Broglie had suggested about 1925 that **electrons** have in some respects the characteristics of waves, and deduced, for the wavelength equivalent to a moving electron, the expression $\lambda = h/mv$, in which m and v are the mass and speed of the electron and h is Planck's constant. If the electron is moving, for example, with a speed corresponding to 65 **electron volts** of energy, the corresponding "de Broglie wavelength" is 1.52 angstroms, which is in the x-ray range. This led Davisson and Germer to see whether electrons might be reflected from crystals after the manner of x-rays. They used a single crystal of nickel cut parallel to the (111) planes, and upon varying the electron speed at a fixed angle of incidence, they found not only a distinct "regular" reflection but also a series of diffraction maxima strikingly similar to those obtained with the same crystal for x-rays of varying wavelength. The differences observed were satisfactorily explained as due to the refraction of the nickel for the electron waves. (L.D.W.)

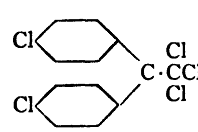
DAW. Jackdaw.

DAY. Time.

DB. Decibel.

D.C. Direct Current.

DDT. An insecticide that has attracted widespread attention. It is currently made by reaction of 1 mol chloral ($CCl_3 \cdot CHO$) and 2 mols chlorobenzene ($Cl \cdot C_6H_5$) in the presence of concentrated sulfuric acid. The principal product of this reaction is DDT but accompanied by other isomers and by-products. DDT is 2,2-bis-(4-chlorophenyl)-1,1,1-trichloroethane, of formula



of melting point 103° C. minimum for "purified," of setting point 88° C. minimum for "technical." The technical grade is that specified by and produced for the U. S. Government, and the specifications for both purified and technical grades were adopted July 10, 1945, by the Manufacturing Chemists' Association of the U. S. "Freon 12" (dichlorodifluoromethane) liquid under pressure, forms a mist with DDT present, when released to the atmosphere, sufficient to kill the insects in the surrounding area—this is the principle of the "insect bomb." The U. S. Department of Agriculture terms it the most potent single insecticide ever discovered.

Dusted into clothing, it protects against the body louse, which carries epidemic typhus. (See **Rickettsial Diseases.**) In contrast to World War I, in which typhus accounted for many thousands of deaths among troops, the disease has been under complete control in World War II. Mosquito control with DDT is also highly effective; walls sprayed with the material will remain lethal to mosquitoes and flies for several months. The toxic effects of DDT on man, and its effect on wild plant and animal life, have not been completely worked out. As far as experimental work has proceeded, it appears that the agent is extremely potent and relatively safe. (R.K.S., D.M.H.)

DEAD CENTER. In machine tools, the term applies to the stationary center on which work rotates while be-

ing machined. In a **lathe**, the dead center is mounted in the tailstock. In heavy-duty lathes, the pressure on the pivot bearing effected by the center holes and the dead center is often so great that the dead center, or the center hole in the work, may wear excessively, and a rotating dead center, consisting of a center mounted in ball bearings carried in the shank which fits the tailstock sleeve, is often used. In grinding machines both centers are frequently stationary.

A steam engine is said to be on dead center when the piston is at one end of its stroke and the crank, connecting rod, and piston rod are in alignment. In this position, the steam pressure does not exert a rotative force on the crank, since it is transmitted directly to the shaft and bearings. (H.C.H.)

DEAD LOAD. **Load.**

DEAD MEN'S FINGERS. Porifera. A branching **sponge**, *Chalina arbuscula*, found off the Atlantic coast of the United States. Its branches are rounded finger-like projections of white or light gray color. (A.W.L.)

DEAD RECKONING. The meaning of this **navigation** term can be best understood from a consideration of its probable origin. Early navigators deduced their positions at any time by using the distances and directions of motion of their ship since leaving some previously known position. Such positions were determined at frequent intervals and early **log** books contained a column for entering them and this column was headed by the abbreviation "ded. pos." The calculating, or "reckoning" necessary to obtain the entries for this column, was known as "ded reckoning" and is now written as dead reckoning.

Dead reckoning is fundamental for the methods of modern navigation and should be clearly understood **Pilotage, radio navigation, celestial navigation** and other methods for determining positions of a ship or plane, all involve the use of dead-reckoning methods. This is particularly true in the case where two **lines of position** are not observed simultaneously, and the fix must be found by moving one or both of the lines by dead reckoning.

There is a conflict of opinion among modern sea navigators as to just how much material should be included in the dead-reckoning (DR) position. It is certainly true that originally only the **heading** of the ship and the distance run on that heading were included. Some modern sea navigators cling to the original meaning of the term. The effects of **current** and **leeway** may be computed independently and the DR position corrected to an estimated position (EP). Some sea navigators include all known or suspected motions of the ship in their dead reckoning and call the resulting position either DR or EP.

It is an established procedure in air navigation to include the movement of the plane through the air (heading and air distance), and the movement due the motion of the air itself (wind direction and speed), in determining a DR position. In air navigation the term estimated position (EP) is used in connection with **celestial navigation** and is discussed in the article on that subject.

Before entering upon a discussion of actual methods of dead reckoning, it should be clearly understood that certain errors are bound to appear in the data employed in the calculations. These may be listed under five groups: **compass corrections**, steering, **patent logs** or **air-speed meters**, leeway of a seaborne ship, and predicted current or **wind**. Under the most favorable conditions, the dead-reckoning position is somewhere within a circle whose center is the DR position and whose radius is between 1 and 2% of the distance run. In conditions of rough sea, or turbulent air, the radius may increase to more than 5% of the distance run.

The graphical method of solution is used by practically all air navigators, and by a majority of those on the sea. This is essentially the graphical addition of **vectors**. In the determination of the old-fashioned DR position, the vectors used are total motions within given periods of time. These vectors are drawn to proper scale of distance on a **mercator chart**, mercator plotting sheet, or **small-area plotting sheet**, with the tail of the first vector resting on the last-known position, known as the point of departure, and the head of the final vector at the DR or EP position. All vectors must be properly labelled; the direction of each being the heading and the length proportional to the distance run.

The graphical method of solution is illustrated in the following case: At 1200 a ship is in latitude 43° 35′ N and longitude 34° 38′ W. At 1200 the ship is on heading 150°, speed 12 knots, at 1430 heading altered to 125°, speed 12 knots, at 2000 heading altered to 030°, speed 12 knots, at 2400 heading altered to 320°, speed 12 knots. The vector diagram is drawn on a small-area plotting sheet and properly labelled as shown in Fig. 1. The

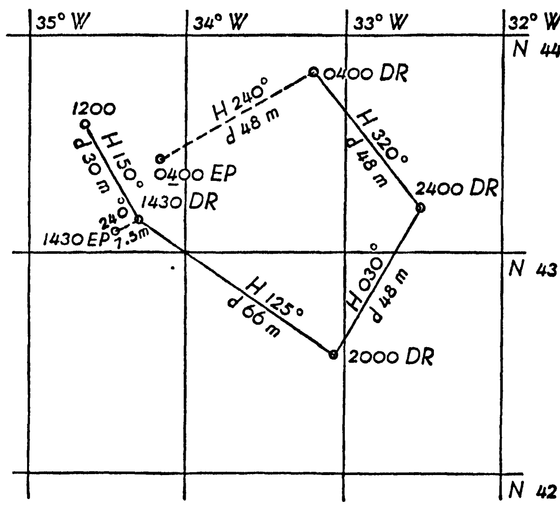


Fig. 1.

various distances are obtained for the vectors by simply multiplying the speed by the time. From this diagram the DR positions for any desired times can be read off directly. For example, the position at 1430 L = 43° 09′.0 N & Lo = 34° 17′.7 W and at 0400 L = 43° 49′.5 N & Lo = 33° 12′.0 W.

In case a current is predicted for this region, an additional vector may be added to any DR position to obtain the estimated position. For example, if in the above situation we assume a current to set 240° with drift 3 knots, vectors (shown dotted in the figure) in direction 240° and lengths 7.5 and 48 miles are added at the 1430 and 0400 DR positions respectively. This yields a 1430 EP L = 43° 05.3 N & Lo = 34° 26.6 W and 0400 EP L = 43° 25.5 N & Lo = 34° 09.4 W. If leeway is present it should be treated as an additional compass correction to each heading, as explained in the article on **leeway**.

The graphical method of solution for dead-reckoning problems requires a considerable amount of paraphernalia, e.g., plotting sheet, parallel rulers or protractor, scale, either pad and pencil or a **dead-reckoning calculator** for arithmetic computing, and most important of all, a flat surface for doing the drawing. On large ships or planes the navigator has the needed space, and the chart table is frequently equipped with a drafting machine which simplifies the plotting. On small boats or planes sufficient space for plotting is difficult to find. Computational methods are just as rapid as those involving plotting and they certainly yield more accurate re-

sults. However, it should be emphasized that the advantage of computational methods is only that of convenience in space, for the plotting methods are fully as accurate as the data warrants.

In the computational method the first step is to solve the right triangle in which the heading vector is the hypothenuse, with the difference of latitude (DL), and the departure (dep) the two legs. The DL is added algebraically to the latitude (L_1) of the point of departure, calling DL + when north, and − when south. The DR latitude (L_2) is then $L_2 = L_1 + DL$. The departure must be converted from nautical miles to difference in longitude (DLo) in minutes of arc by the method of **middle-latitude sailing,** using for the mid-latitude $L_m = \frac{L_1 + L_2}{2}$. The DLo is added algebraically to the longitude (Lo_1) of the point of departure, calling DLo + when west, and − when east. The DR longitude (Lo_2) is then $Lo_2 = Lo_1 + DLo$. Three-place computing, using slide rule or traverse tables is sufficient to attain all accuracy warranted by the data. To illustrate the computational method: At 0815 a ship is in latitude 41° 42′ N & Lo = 35° 25′ W. The ship proceeds along heading 243° at 14 knots, and the DR position at 1200 is desired.

L_1 41° 42.0 N	H 243°	Lo_1 35° 25′.0 W
DL 23.8 S	d 52.5 m	DLo 1 02′.5
L_2 41 18.2 N	dep 46.8 W	Lo_2 36 27′.5 W
	L_m 41°.5	
	DLo 62.5 W	

The actual numbers were read directly from traverse tables and the total time required for solution was 2 minutes. The equipment used was a pencil, scratch pad, and traverse tables.

In more complicated cases where a number of different headings and distances are used, and in a region where a current is predicted, we set up what is known as a traverse form in which the columns N, S, E, and W refer to the direction of the individual DL's and departures. At 0400 a ship is on heading 200°, speed 15 knots, and is in latitude 40° 21′.3 N and longitude 124° 34′.6 W. At 0723 the heading is altered to 300°, speed 15 knots, at 1136 heading altered to 030° speed 15 knots, at 1314 heading altered to 340° speed 15 knots. In this region there is a current setting 140° 2 knots. The traverse form used in determining the DR position at 1600 is given below:

TRAVERSE FORM

H	Time	d	N	S	E	W
200°	3 h 23 m	50.8 m		47.7		17.4
300	4 13	63.3	31.8			54 9
030	1 38	24.5	21.2		12.2	
340	2 46	41.5	39.0			14.2
		Sums	92.0	47.7	12.2	86.5
		Total	44.3			74.3

L_1 40° 21′.3 N	dep 74.3 m W	Lo_1 124° 34′.6 W
DL 44.3 N	L_m 40°.7	DLo 1 37.9 W
L_2 41 05.6 N	DLo 97.9 W	Lo_2 126 12.5 W

To this DR position the current motion must be added to attain the estimated position. The current motion in 12 hours is 24 miles along 140°, for which DL = 18.4 S, dep = 15.4 m E, and in mid-latitude 40°.7 DLo = 20.4 E. Applying these to the DR position we have EP L = 40° 47′.2 N & Lo = 125° 52 1 W.

Whenever a fix is obtained, a DR position is also obtained. The difference between the two positions is always attributed to "current" by sea navigators, never to errors in their data or obtaining the DR position. Here the difference in opinion as to whether or not leeway and current should be included in obtaining the DR position introduces confusion. If an old-fashioned DR position (i.e., without current or leeway included) is used, then the difference between fix and DR may be the actual current. If an EP is used, the difference between this position and the fix is a residual current, supplemental to that already used in the determination of the EP. In either case the difference is called current with set equal to the direction from the DR position to the fix, and drift the distance between the two positions divided by the number of hours elapsed from the point of departure for the dead reckoning. These so-called currents are entered in the ship's log book and later forwarded to the Coast and Geodetic Survey or the Hydrographic Office where statistical discussions yield improvements to previously predicted values.

In air navigation a slightly different procedure for finding DR position is employed. In the first place, the work is always done by constructing the vector diagram. Before plotting the total distances from the point of departure, a velocity-vector diagram is used to determine the **course** and ground speed made good along this course. The heading and air speed of the plane are drawn as one vector, and to this is added the vector representing the direction toward which the wind is blowing and the wind speed. The vector sum is a vector giving course and predicted ground speed. Unfortunately, the first man who erected a weather vane so balanced it that the arrow pointed into the wind instead of with it. Still more unfortunately, the weather bureaus have retained this archaic method of publishing wind directions, and air navigators must be particularly careful in constructing their diagram. After the course and ground speed along the course have been obtained, then a DR position can be obtained by plotting these in the same manner that the sea navigator plots heading and ship's speed. At 0916 a plane is known to be in latitude 41° 52′ N & longitude 56° 34′ W. The plane is heading 243° with true air speed 110 knots and the predicted wind is from 305°, speed 35 knots. The pilot wishes to determine the course and ground speed of the plane and the DR position at 1045. The vector-velocity diagram is shown in Fig. 2(a). The wind vector, *ew*, must be

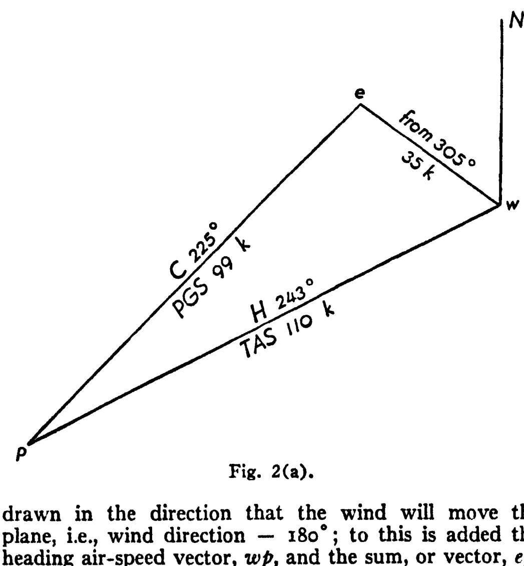

Fig. 2(a).

drawn in the direction that the wind will move the plane, i.e., wind direction − 180°; to this is added the heading air-speed vector, *wp*, and the sum, or vector, *ep*, is the course and speed made good. In this case the course is found to be 225° and the ground speed 99 knots. With these quantities determined, the DR position is found by plotting the distance-vector diagram shown in Fig. 2(b). The course 225° is laid off from the 0916 position on a Mercator plotting sheet or a small-area plotting sheet, and the distance 99 × 1 h 20 m = 146 m is measured off on the proper scale, giving the 1045 DR position. If the heading is altered, a new velocity-vector diagram must be constructed and a new course and ground speed obtained. Then a distance

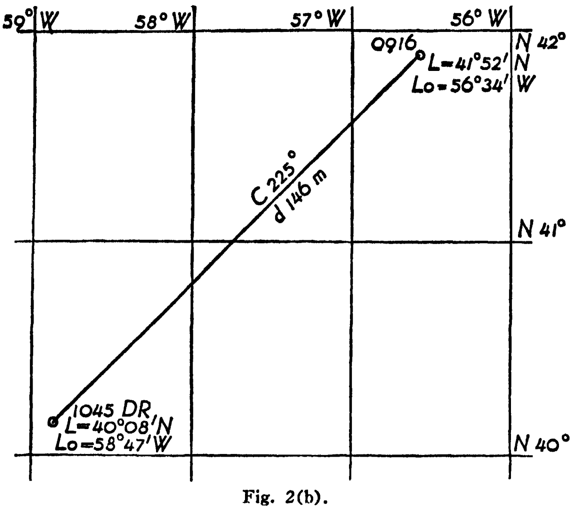

Fig. 2(b).

vector would be added to that already found, and the DR position found at any desired time.

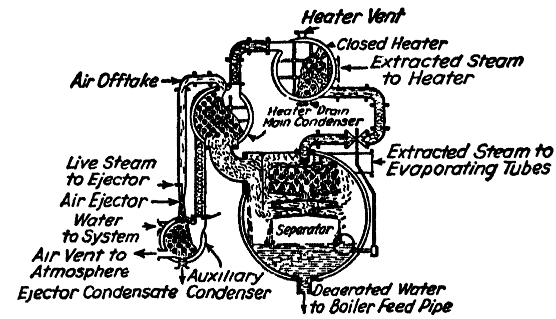
The solution of the velocity-vector diagram is facilitated by the use of any one of a number of **dead-reckoning computers.**

In case a reliable fix is obtained at the same time a DR position is found, and the two do not coincide, the air navigator always assumes that the difference is due to an error in the predicted wind. The line between the point of departure and the fix is known as the track if but one heading is used, or the track made good if the plane has changed heading since leaving the point of departure. A discussion of this problem will be found in the article on **Air Plot.** (W.K.G.)

DEAD-RECKONING COMPUTER. A mechanical device for rapidly setting up the complete velocity-vector diagram required for the solution of **dead-reckoning** problems in air **navigation** is known as a dead-reckoning computer. Nearly all of the many types of computers which have been developed within the past 10 years may be adapted to the solution of all triangles necessary during flight. A **navigational computer** is usually incorporated with the dead-reckoning computer, and the one instrument will suffice for all computing necessary during a flight.

Before attempting to use any computer, the navigator should thoroughly understand the actual drawing of all triangles required for the solution of the various problems met with in flight. With that understood, and after a careful study of the directions supplied with each computer, the instrument will save considerable time and give results accurate enough for most practical purposes. (W.K.G.)

DEAERATION. As water dissolves, to a greater or less extent, many common gases, in the natural state it will contain a certain amount of dissolved gases, such as oxygen and carbon dioxide. Deaeration is the removal of this dissolved gas. Deaeration at the present is practiced where the gas that water contains would have undesirable effects. Often dissolved oxygen is objectionable because of its corrosive action. This is true in the case of the high-pressure steam boiler, where a small amount of oxygen dissolved in the feed water may become quite active in attacking the boiler metal under the high pressure and temperature conditions there experienced. Steam boiler operators often treat their boiler feed water in deaerators to remove this oxygen. These deaerators are either of the deactivating or the heating type. Deactivating types employ chemical means of deaeration. A representative deactivating deaerator consists essentially of a tank containing large surfaces of scrap iron. When water containing dissolved oxygen is brought into contact with this iron, most of the **oxygen** combines with the **iron,** and is thereby removed from the water. Deaerating action in a heating-type deaerator is obtained by first reducing the solubility of the gas through heating the water (under pressure); second, reducing the pressure and producing explosive boiling; and third, controlling the agitation of the water subsequent to the second action in a partially evacuated region. The figure shows a heating-type deaerator. Water



Elliott type "J" deaerator.

drawn from a supply line circulates through the tubes of the auxiliary and main condensers. It then flows under the heater where it is heated to the desired temperature. The heated water flows down into the separator, where it boils violently, giving off the dissolved gases. Vapor and gases are carried off through the condenser, in which the vapor is condensed for return to the deaerator. The gases are removed by an air pump. (F.T.M.)

DEATH. The termination of vital processes in the organism. The physiology of death has been studied extensively and various explanations have been offered of its causes without furnishing true understanding. It often occurs through accident, but under entirely normal conditions also it takes place after a lapse of a period characteristic of the species. Following maturity the metabolic processes of the individual become slower through senility until at last some vital part fails completely. Only animals that reproduce by binary fission, notably the 1-celled species, are immune from normal death. In these forms the identity of the parent is merged with that of its offspring and death is always accidental. (A.W.L.)

DEATH WATCH. Insecta, Coleoptera. A small **beetle** of the family Anobiidae which burrows in solid wood in buildings. By striking its head against the walls of the burrow it produces a sharp sound which can be heard in quiet places. It has been supposed, superstitiously, to foretell death. (A.W.L.)

DEATH'S HEAD MOTH. Insecta, Lepidoptera. A large European **sphinx moth** whose **thorax** bears a light mark shaped like a skull. (A.W.L.)

DEBRIDEMENT. The treatment of wounds, especially traumatic, dirty, crushing wounds, by means of excising all injured, contaminated, or devitalized tissue. (R.S.M.)

deBROGLIE WAVE. Davisson-Germer Experiment; Wave Mechanics.

DECADE BRIDGE. Bridge.

DECALAGE. The wings of a biplane are usually set parallel to each other. This is not absolutely necessary, and some designers have preferred characteristics ob-

tained when the wings are set at a slight angle to each other. Decalage is the angle between the **chords** of the two wings of the biplane. It is rare for decalage to amount to more than 2 or 3°. (F.T.M.)

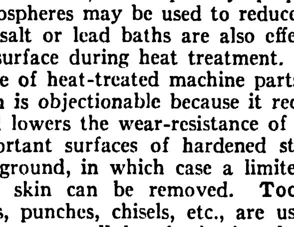
DECAPODA. 1. The **shrimps** and **prawns, lobsters, crayfishes,** and **crabs,** constituting a large and important order of **crustaceans.** The **thorax** is covered by a **carapace** and bears five pairs of appendages, the first pair chelate grasping structures and the remaining four formed for walking. 2. The **cuttlefish, squids** and related forms, constituting an order of **cephalopods.** They possess ten arms, with stalked suckers provided with horny rims, and have a well-developed internal shell. (A.W.L.)

DECARBURIZATION. Reduction in carbon content at the surface of **steel** or **cast iron** by heating in air or other oxidizing or reducing gases. In heating for hot rolling, **forging,** or **heat treatment,** decarburization is usually objectionable, and specially prepared neutral furnace atmospheres may be used to reduce or eliminate it. Molten salt or lead baths are also effective in protecting the surface during heat treatment.

In the case of heat-treated machine parts, surface decarburization is objectionable because it reduces **fatigue** strength and lowers the wear-resistance of **bearing** surfaces. Important surfaces of hardened steel parts are often finish-ground, in which case a limited amount of decarburized skin can be removed. **Tool steels** for cutting tools, punches, chisels, etc., are usually ground sufficiently to remove all decarburization; however, many tools and dies are machined to finish dimensions before hardening and extreme care must be taken to protect the surface.

Decarburization is intentional in the processing of low-carbon sheet steels for electrical applications. In the production of **malleable cast iron** by annealing white cast iron decarburization is beneficial. (R.H.H.)

DECAY COEFFICIENT. Certain processes studied in physics progress at a rate diminishing in accordance with an **exponential** function of the time; such, for example, as phosphorescence and **radioactive** emission. The falling off or "decay" of such a process may be represented by an equation giving the intensity at time t as $I = I_0e^{-Ct}$, in which I_0 is the intensity at the beginning of the time t and C is the "decay coefficient."



Typical exponential decay curves. The decay coefficient in B is greater than in A.

Closely related to C is the half-value period, which is the time required for I to fall to ½ its original value I_0; it is equal to $0.69315/C$. Thus, if the half-value period of radium B is 1608 sec., its decay coefficient C is

$$\frac{0.69315}{1608 \text{ sec.}} = 0.000431/\text{sec.}$$

This means that approximately 0.000431 of the substance existing at any instant disintegrates during the ensuing second. The reciprocal of C, called the "decay modulus," represents the time required for I to diminish to $1/e$ or 0.3697 of its original value I_0. It is equal to 1.4427 times the half-value period; for the decay of radium B its value is therefore 2320 sec. (L.D.W.)

DECCA NAVIGATION. Decca navigation is a system of **hyperbolic navigation** which employs low-frequency continuous-wave radiation. The system has been under experimentation for a number of years, but has not as yet proved to be entirely satisfactory in practice. It does have certain definite possibilities, and is worthy of consideration.

The master and any slave station radiate continuous waves whose frequencies are related by a simple fraction, say one fourth. The radiations from the two will be in phase when the distances from the stations differ by even multiples of a specified unit. This unit is a function of the wavelengths radiated.

In practice a master and two slave stations are used. The receiving set reduces all three to a common frequency and phase meters indicate the relative phase of each slave to the master. The accuracy of the setting of the phase meter is such that differences in distance may be determined with an accuracy of the order of magnitude of 100 feet, and this is independent of distance from the base line. However, there is complete ambiguity of position since there is no positive method of determining the number of complete phase changes between the observer and either station. Attempts are being made to overcome this difficulty by modulating envelopes on the carrier wave.

In spite of the ambiguity mentioned above, the system is of great accuracy and value when used in proceeding to some specified objective. A **line of position,** involving the master and one of the slave stations, is selected which passes through the desired objective. The pilot must get his ship onto this line and then set his phase meter. If he then proceeds so that the phase meter setting remains constant he must be following the hyperbola directly to his objective. The hyperbolic lines from the master and the other slave will intersect the hyperbolic track along which the ship is proceeding The pilot computes the number of complete phase changes that are to be expected, between the point of departure and the objective, along the line that he is following. When this number, plus any remaining fractional phase change, has been completed the pilot must be directly over the objective. (W.K.G.)

DECIBEL. A commonly used unit of relative power, especially in expressing acoustic or electric power outputs in terms of some arbitrarily specified standard. The decibel is one tenth of a **bel.** Devices emitting sound energy, such as **loud-speakers,** or those which transform sound energy into electrical energy, such as **microphones,** are commonly rated in decibels above or below some reference device of similar type.

The decibel is a power ratio, equal to the tenth root of ten or about 1.259. Thus if a radio receiver, playing at a certain "volume" level, is turned up until the acoustic power output has increased by 25.9%, its new level is said to be one decibel above the original level. To raise the level 2 decibels would require a power step-up of $1.259 \times 1.259 = 1.585$; that is, of $\sqrt[10]{10} \times \sqrt[10]{10} = \sqrt[5]{10}$. An increase of 10 decibels would require a 10-fold output of power, since $(\sqrt[10]{10})^{10} = 10$. This last increase is called a **bel,** a term derived from the name of Alexander Graham Bell, inventor of the telephone. Twenty decibels or 2 bels corresponds to a 100-fold increase of power; and so on. To be quite accurate one should say, not that 3 decibels equals 3 times 1 decibel, but rather that it is the cube of 1 decibel.

If two power outputs to be compared are denoted by p_1, p_2 and their difference of level, in decibels, is denoted by d, then from the above definition,

$$\frac{p_2}{p_1} = (\sqrt[10]{10})^d = 10^{\frac{d}{10}}.$$

The relation is more conveniently applied in the logarithmic form,

$$\log\frac{p_2}{p_1} = \frac{d}{10},$$

or

$$d = 10 \log\frac{p_2}{p_1}.$$

For example, the electric power output of a certain microphone is 18 decibels higher for a musical tone of 1500 cycles per sec. than for a 500-cycle tone of the same intensity. This means that, for the same acoustic power input, the electric power output of the microphone at 1500 cycles exceeds that at 500 cycles in the ratio $\log^{-1} 18/10$, or about 63 to 1.

Generators of voltage are also often expressed in decibel measure, especially if the voltage has an acoustic origin. But since the power of a generator in a given circuit is proportional to the square of the voltage, $p_2/p_1 = (E_2/E_1)^2$, or $\log p_2/p_1 = 2 \log E_2/E_1$. Therefore, for such cases,

$$d = 20 \log\frac{E_2}{E_1}.$$

It is an interesting circumstance that the smallest change of sound intensity that the normal human ear can detect is approximately 1 decibel, whatever the original intensity. It may have been this fact that first suggested such a unit. (L.D.W.)

DECIDUOUS PLANTS. Plants which drop their leaves at the end of the growing season are called deciduous plants. (R.M.W.)

DECILE. A decile is a measure of position. The nine deciles $D_1, D_2, \cdots, D_9$ are the values of the **variates** which divide a distribution into ten equal parts. They are found by observation in a **serial distribution** after the items are arranged in order of magnitude, and in a **frequency distribution** by interpolation in the **cumulative frequency distribution.** (L.A.A.)

DECK BRIDGE. Bridge.

DECKEN STRUCTURE. Used by structural geologists to designate a series of great overthrust folds with nearly parallel and horizontal axial planes. (R.M.F.)

DECLINATION. The declination of a celestial object is the coordinate in the **equatorial** system of **spherical coordinates** measured in the plane of the **hour circle** through the object from the equator to the object. In case the object is between the equator and the north celestial pole the declination is said to be north or positive (+), otherwise the declination is south or negative (−). Declination is ordinarily measured either with a **meridian circle** or an **altazimuth** instrument.

The term declination is used by surveyors, and a few others, in place of **variation** to describe the angle between true and magnetic **north.** Navigators, both air and sea, always use the term variation for this angle. (See **Compass Corrections.**) (W.K.G.)

DECOMPOSITION OF VECTORS INTO COMPONENTS. Vector Addition.

DECOUPLING FILTER. In most multistage **amplifiers** there are certain circuits, such as voltage supplies, etc., common to more than one stage. Since these common circuits provide a path through which energy may be fed from the output back into the input of some stages, serious feed-back problems would result if something were not done to prevent them. The usual remedy is to insert a decoupling filter in those plate and grid leads which connect to points common to other plate or grid leads. These filters are frequently resistances in series with the lead and a **by-pass** condenser from the plate or grid side of the resistor to ground. The resistance used must be low enough not to cause a serious loss of voltage and the condenser should have a reactance which is low compared with the resistance at the lowest frequency for which the circuit is designed. Where the resistance would produce too much d-c voltage drop or where it does not give enough filtering action an inductance is sometimes used. For still more effective filtering a second resistance and condenser in cascade may be used. (L.R.Q.)

DEDENDUM. In a gear tooth, the distance from the pitch circle to the root circle or bottom of the tooth space. (H.C.H.)

DEDIFFERENTIATION. A process of change from a more specialized to a less specialized condition. (A.W.L.)

DEER. Mammalia, Artiodactyla. Hoofed animals which have solid bone antlers in the male or in both sexes. These antlers are shed each spring. The deer constitute the family Cervidae.

The typical deer are represented by the red deer of Europe, *Cervus elephas,* and the **elk** or wapiti, *C. canadensis,* and Virginia or white-tailed deer of North America, *Odocoileus virginianus.* The group also includes Asiatic species known as the shou and maral. Asia is the home of many species of deer which fall into several groups known as the sambar group, the fallow deer group (*Dama*), the muntjacs (*Cervulus*), and the tufted deer (*Elephodus*). Several species not associated with these groups are also found in Asia, among them the chital or Indian spotted deer, *Axis axis,* the **reindeer,** *Rangifer,* and the Chinese water deer, *Hydropotes.*

The North American fauna includes the **caribou,** *Rangifer,* related to the reindeer, and the **moose,** *Alces americana,* which is related to the elk of Europe, in addition to the mule deer, *Odocoileus hemionus,* of the west and the Virginia deer, *O. virginianus.* Mexico and Central and South America are the home of the brockets and guemals and of several other kinds of deer.

Many species of deer are among the finest of game animals They have been hunted to extinction in some areas and have retreated readily before the advance of man, but through proper protection and management they are being maintained in many sections of the United States in satisfactory numbers. The flesh is excellent. (A.W.L.)

DEER FLY. Insecta, Diptera. Small **horse flies** with banded wings which are abundant in the eastern woods. In the west the name is applied to **snipe flies.** All species are annoying to man. (A.W.L.)

DEFICIENCY DISEASE. Any disease due primarily to lack of certain essential substances such as **vitamins,** or minerals like iron, calcium, etc. The deficiency is usually on the basis of poor diet. The common deficiency diseases are **beri-beri, scurvy, pellagra,** alcoholic **neuritis,** and **rickets.** (D.M.H.)

DEFINITE INTEGRAL. Let $f(x)$ be a **continuous function** in an interval (a, b). Suppose this interval to be divided and redivided into parts in any manner such that as the process is continued the lengths of the parts all approach zero as a limit. At any stage of the process let $\Delta x_1, \Delta x_2, \cdots, \Delta x_n$ denote the parts, and let z_1 denote any point in Δx_1, z_2 any point in $\Delta x_2, \cdots, z_n$ any point in Δx_n. Then form the sum of the products:

$$\sum_{i=1}^{n} f(z_i)\Delta x_i = f(z_1)\Delta x_1 + f(z_2)\Delta x_2 + \cdots + f(z_n)\Delta x_n.$$

As $n \to \infty$ and each $\Delta x_i \to 0$, this sum approaches a **limit,** which is independent of the mode of division of the interval (a, b) into parts Δx_i and the choice of the z_i in the subintervals Δx_i. This limit is denoted by the symbol

$$\int_a^b f(x)dx,$$

and is called the definite integral of $f(x)$ between the **limits** a and b; a is called the lower limit and b the upper limit of the integral.

The definite integral $\int_a^b f(x)dx$ has the properties:

$$(1) \quad \int_a^b f(x)dx = -\int_b^a f(x)dx,$$

$$(2) \quad \int_a^b f(x)dx = \int_a^c f(x)dx + \int_c^b f(x)dx.$$

If $\int_a^x f(x)dx = F(x)$, then $\frac{d}{dx}F(x) = f(x)$, so that $F(x)$ is an integral of $f(x)$.

If $F(x)$ is any known integral (**indefinite integral**) of $f(x)$, then

$$\int_a^b f(x)dx = F(b) - F(a).$$

This is the fundamental formula for the evaluation of a definite integral in terms of the indefinite integral found by inverse **differentiation.**

If the substitution $x = \phi(t)$ is made in the definite integral $\int_a^b f(x)dx$, we obtain

$$\int_a^b f(x)dx = \int_{t_1}^{t_2} f[\phi(t)]\phi'(t)dt,$$

where t_1 and t_2 are values of t such that $a = \phi(t_1)$, $b = \phi(t_2)$, and $\phi'(t)$ is the derivative of $\phi(t)$ with respect to t. (L.L.S.)

DEFINITE PROPORTIONS, LAW OF. The proportions by weight of the different elements which make up a chemical compound are the same in every sample of this compound. (See **Chemical Composition.**) (R.K.S.)

DEFLATION. In geology, deflation is the action of the wind in removing unconsolidated fine-grained **sediments** from a land surface. In 1895 dust fell in Missouri which must have come entirely from western Kansas and Nebraska, since the intervening country was covered with ice and snow. Dust from the Sahara has been blown over Germany and England (transported by air 2000 miles). (R.M.F.)

DEFLECTION. In engineering there are two common uses of the term deflection—deflection under load and deflection angle in surveying.

In general loads acting on an elastic structure cause a linear displacement of the several parts of the body, relative to their original position. This is known as deflection. Deflection is characteristic of all structures since all materials are elastic to a certain extent. Fig. 1 represents a beam which has been bent by the

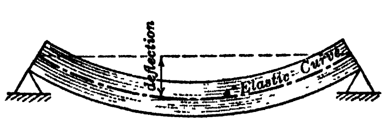


Fig. 1. Deflection of a bent beam.

action of an external load. The deflections are the ordinates between the original and final positions of the **elastic curve.** The amount of deflection depends upon the load, stiffness of the material and the dimensions of the beam. The stresses cause the top fibers to compress and the bottom fibers to elongate. Since Hooke's Law states that **stress** is proportional to **strain** (deformation) as long as the stress is below the **proportional limit,** the stress in the beam due to bending will be proportional to the deformation of the fibers. The beam will come to rest or be in a state of equilibrium after the application of a load, when at every section the **moment** of the internal stresses equals the moment due to the external load.

Deflection is an important element in the design of a load-carrying structure. If strength is the limiting condition for which a beam is designed, the design should be tested for deflection to make certain that the displacements are within allowable limits. Deflection rather than strength often governs the design. This is especially true in the design of beams for buildings, where small deflections, only, are permissible, because of the tendency of the deflection of the beams to crack terrazzo floors, plastered ceilings, etc. Solid rib and trussed bridges are also subject to deflection. Large steel bridges and building trusses are always cambered (see **Camber**) to counteract the effect of deflections.

The numerical value of the deflections of beams may be obtained by such methods as Double Integration, Conjugate Beam, Moment Areas and Work. The deflections in rib and framed structures may be computed by methods of Work, Elastic Weights, etc. The Williot-Mohr Diagram furnishes a graphical means for obtaining the deflection of trussed frames. These methods are given in any standard structural textbook.

Maxwell's Law of Reciprocal Deflections is very useful in the analysis of **indeterminate structures.** This theorem, which may be applied to any loaded structure, states that the deflection of a point A in an arbitrary direction AC due to any **load** P applied at B in a direction BD is equal to the deflection of B in the direction BD when the load P is applied at A in the direction AC. (See Fig. 2.)

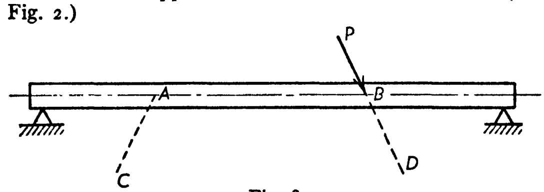

Fig. 2.

In surveying, the angle between a line and the extension of the preceding line is called a deflection angle. See Fig. 3. When the survey is a closed **traverse**

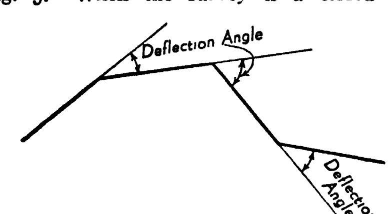

Fig. 3. Deflection angle.

the sum of the deflection angles must equal 360 **degrees. Circular curves** are frequently laid out by the method of deflection angles which is illustrated in Fig. 4.

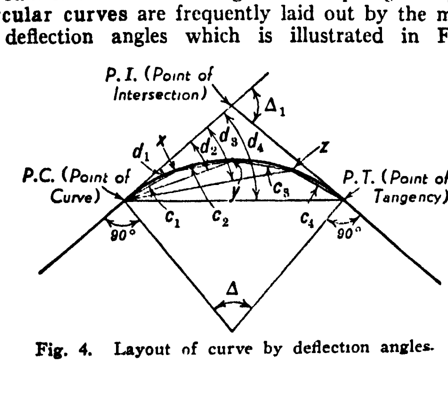

Fig. 4. Layout of curve by deflection angles.

Before it is possible to lay out points on the curve it is necessary to locate the P.C., P.I., and P.T. and obtain the central angle Δ which is numerically equal to the deflection angle Δ_1. Having the value of Δ_1, the deflection angles d_1, d_2, etc., may be calculated from the assumed **chord** lengths c_1, c_2, etc. The **transit** is first set up over the P.C. and sighted on the P.I. The deflection angle d_1, which gives the direction of the line from P.C. to x, is then turned off by means of the transit. The chord length c_1 is next measured on the ground by a steel tape (see **Chain**), which definitely fixes the positions of point x. Point y may be located by turning off the deflection angle d_2, and measuring the chord c_2 from the point x. Other points on the curve may be set in a similar manner. From the geometry of the figure it can be seen that the deflection angle (d_4) to the P.T. is equal to one-half of the central angle. (C.W.C., F.T.M.)

DEFLECTIVE FORCE. **Wind Equations.**

DEFORMATION. The change in the shape of a body which accompanies a stressed condition is called deformation or strain. The total amount of deformation in one direction is the total deformation. Unit deformation is the deformation per unit of length. Permanent deformation is known as set. If an axial load is applied to a body, the length and lateral (cross-sectional dimensions, are changed. **Poisson's** ratio is the ratio of lateral unit deformation to longitudinal unit deformation.

Deformation which is the result of a flexural stress (see **Flexure**) is called bending deformation. Shearing or shear deformation is caused by **shearing stress.** (C.W.C.)

DEGRADATION OF ENERGY. **Available Energy.**

DEGREE. The electrical degree is $\frac{1}{360}$ of a cycle of alternating current representing an electrical revolution.

The geometric degree most commonly used is the unit measured by the central **angle** subtended by $\frac{1}{360}$ of the arc of a great circle. This unit of angular measurement has been extended to a great many practical uses, as, for example, the reading of compass **bearings** in degrees. A right angle contains 90°; a minute is $\frac{1}{60}$ of a degree, and a second is $\frac{1}{60}$ of a minute.

The thermal degree represents molecular activity, in that **temperature** depends upon molecular velocity. Temperature is ordinarily measured by the expansibility of a gas or liquid. The unit of measurement is the degree of temperature. The two most commonly used scales are the Fahrenheit and Centigrade. In each, the difference in the positions indicated by the thermometer index, when subjected, first, to the temperature of melting ice, then to the temperature of boiling water, both under atmospheric pressure, is divided into a number of equal degrees. In the case of the Fahrenheit scale there are 180 equal degrees, but for the Centigrade there are only 100. Thus a Centigrade degree is a larger unit than the Fahrenheit, the ratio being as 9 to 5. The melting temperature of ice is called zero on the Centigrade, and 32° on the Fahrenheit scale, and the boiling point of water at standard atmospheric pressure is 100° on the Centigrade and 212° on the Fahrenheit scale. (F.T.M., L.R.Q.)

DEGREE DAY. This is a unit employed in the heating and air conditioning field for specifying the nominal heating load in winter. In any one day there are as many degree days as there are degrees Fahrenheit difference in temperature between the mean temperature for the day and 65° F. For example, in a month during which the outside temperature averaged 20° F. for 10 days and 35° F. for 20 days, there are 1050 degree days. This number is found thus: Degree days = $10(65 - 20) + 20(65 - 35) = 1050$.

Some years ago a statistical study determined that the fuel consumption for heating residences varied directly as the difference between some datum temperature and the outside temperature. A suitable datum was found to be 65° F. If the degree days are totaled for a heating period, the fuel consumption during that period, as compared with some other heating period, will be in the same proportion as the number of degree days in the two periods.

This is also a convenient unit for expressing the fuel consumption of a heating plant, since it eliminates weather as a variable. Operators sometimes compute fuel burned per degree day by the heating plant in order to make a comparison with previous operation of the plant. If the fuel quantity is divided by the degree days and by the amount of radiation, building volume, or some other unit of heating load, the result is comparable with similar figures from other heating plants without considering weather conditions. (F.T.M.)

DEGREE OF INDETERMINACY. **Redundancy.**

DEGREE OF REDUNDANCY. **Redundancy.**

DEGREES OF FREEDOM. This term has reference to the various ways in which a system may alter in respect to the configuration of its parts. For example, a system composed of three dimensionless particles has 9 degrees of freedom; for it takes nine independent coordinates to specify the positions of the particles in space, and their arrangement may therefore be changed in nine different ways. A single rigid body, on the other hand, has 6 degrees of freedom, since it may have motions of translation in three coordinate directions and it may also rotate about any one of the three coordinate axes through its center of mass. Any actual motion of the body is in general made up of all six, its linear motion being the resultant of three linear components and its rotation the resultant of three angular components. Each molecule of a diatomic gas has 7 degrees of freedom; viz., the six just mentioned for the molecule as a whole (regarded as a rigid body), and, in addition, one corresponding to the possible vibration of the two atoms toward and from each other. If the body is not rigid, the number of degrees of freedom may be virtually infinite. It should however be added that, because of restrictions imposed by the **quantum theory,** not all of the possible degrees of freedom can in general be expected to participate in changes of molecular energy. (See **Equipartition of Energy.**)

In statistics, the concept of the degrees of freedom, an extremely difficult one to explain mathematically, but very easy to understand intuitionally, was introduced by R. A. Fisher in the **analysis of variance,** the χ^2 test of significance, **tests of independence in contingency tables,** and in **Student's *t* test** for the difference of two means. In the **χ^2 test for goodness of fit** the degrees of freedom n is found by the formula n = number of classes in which the theoretical frequencies are 5 or more, less the number of **statistics** calculated from the **sample,** less one. It is evident that the last one must be subtracted since, when all the first class frequencies are inserted, the last one is uniquely determined in order to give the proper total frequency. We are subtracting the number of linear restraints when we subtract the number of statistics used from the sample in forming the theoretical frequencies. In an $r \times s$ contingency table the degrees of freedom will ordinarily be $(r - 1)(s - 1)$. In Student's t test for the difference of 2 means the degrees of freedom will be $N_1 + N_2 - 2$, where N_1 = number of **variates** in one sample, and N_2 the number of variates in the second sample, if the variates are not paired. In estimating a population **variance** σ^2, we use $\frac{N\sigma^2_s}{N - 1}$, where σ^2_s is the sample

variance, N is the size of the sample, and $N - 1$ the degrees of freedom. In a **randomized block** experiment of r blocks and s varieties in each block, the degrees of freedom for the total sum of squares will be $rs - 1$, for the sum of squares among variety means $s - 1$, among block means $r - 1$, and for error $(r - 1)(s - 1)$. The degrees of freedom are important in all analysis of variance problems. Essentially the degrees of freedom represent the number of independent classes or conditions in certain statistical problems. (L.D.W., L.A.A.)

DEGU. Mammalia, Rodentia. A small animal of Chile and Peru. It resembles the rat but has moderately long ears and a tufted tail. (A.W.L.)

DEHUMIDIFICATION. Removal of saturated vapor from a gas is known as dehumidification. Most dehumidification is concerned with the removal of water vapor from air. This may be done chemically by the exposure of air to a dehydrating chemical such as calcium chloride. This method is rarely practical unless small quantities of air are to be treated.

As air can contain only a definite amount of moisture when completely saturated at some particular temperature, and since the amount of this vapor held at saturation decreases with the temperature, air that is nearly saturated with water vapor may have its water content greatly reduced if its temperature can be reduced. Reduction of temperature may be accomplished through surface cooling by passing the air over cold surfaces or through condensers, or cold water and air may be mixed together, as in the spray-type dehumidifier. (F.T.M.)

DEHYDROGENATION. Dehydrogenation is a chemical reaction involving removal of **hydrogen** from a compound. (See **Reactions Involving Oxidation-Reduction.**) (R.K.S.)

DE-ICERS, AIRCRAFT. Under certain atmospheric conditions ice may form on various parts of aircraft in flight. (See **Icing, Aircraft.**) When this happens to airplanes, flight may be difficult, if not impossible, to maintain, and tragic consequences are a possibility. Fortunately, there have been developed acceptable methods of ridding airplanes of ice accumulations which would interfere with flying characteristics. De-icing equipment might be classified as mechanical, thermal, or chemical. Wings, struts, empennage, and other parts tending to accumulate ice on a leading edge may be protected with mechanical de-icers consisting of rubber tubes that can be inflated and deflated for the purpose of cracking loose accumulations of ice. Propellers and windshields are better treated by heating or with liquid antifreeze solutions. A great amount of developmental work has been done in special refrigerated wind tunnels. Equipment was developed which, after extensive flight testing, has been applied as standard equipment on commercial and military airplanes.

Rubber de-icers contain a series of parallel tubes that can be inflated with compressed air. In operation, tubes of each de-icer are inflated and deflated rapidly, with a rest period between inflations. When not in operation, the tubes collapse against the surface of the airfoil section. While the tubes are flat on the surface, a coating of ice is permitted to form. After a coating is formed, the center tube is inflated, cracking the ice along the leading edge. As the center tube deflates, the outer tubes inflate, loosening and raising the cracked ice from the surface, so that the air stream can get under it and blow it away. Thus the aerodynamic lift of the wing is restored. The air is supplied from air pumps driven from the airplane's engines, with motor-driven distributor valves and pilot control valve inserted in the circuit. The de-icing equipment, consisting of the rubber tubes and the air supply, may add between .1 and .3% to the weight of an airplane. When deflated, the de-icer tubes lie snugly on the leading edge, and do not greatly increase the drag. Only about 35% of the drag of an airplane is profile drag of the airfoils,

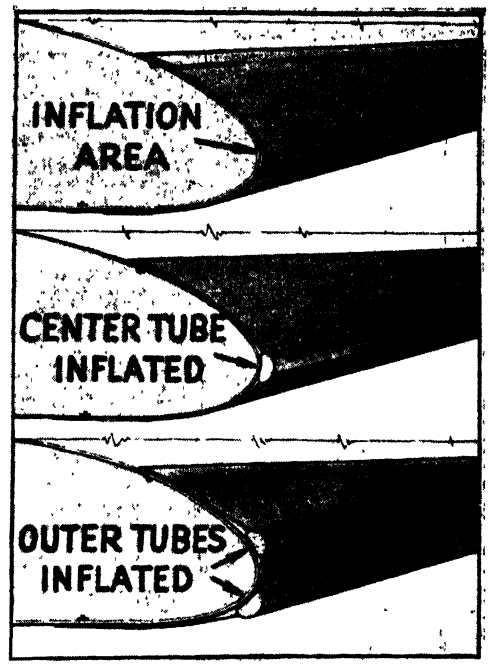

Fig. 1. Rubber de-icer tubes for the wing leading edge (*B. F. Goodrich Co.*).

and the effect of de-icer equipment is to increase the profile drag about 10%. Hence, drag may be increased 3½%, and speed reduced by the square root of 3½%. When the de-icers are in operation, the drag varies; however, because of the nature of the inflation cycle and

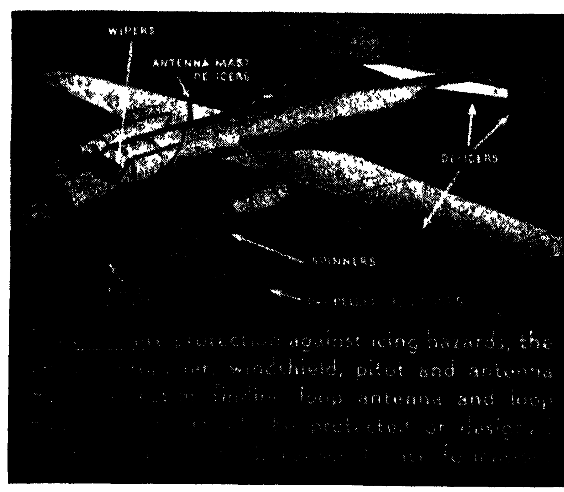

Fig. 2. Points of application of localized de-icing. (*B. F. Goodrich Co*)

the airplane's momentum, the speed is not greatly affected, and experience shows that during operation of the de-icers, the speed is reduced only about 1½%.

In spite of a considerable standardization on mechanical wing de-icers, experimentation with thermal de-icing has continued. This system appears to become more

attractive as flight speeds increase and the slight protuberance of the inflation tubes more severely penalizes aerodynamic performance. Hot air, ducted to the interior of metal skin wings, can rid the wing of ice and not affect the airfoil profile in the least. Some extra drag must be accepted for this system uses an air scoop in the propeller stream to obtain the requisite ram for circulating hot air. When combined with cabin air heating (a necessity on airliners) the thermal de-icing equipment is estimated to increase airplane weight from ½% to 1½%. The air ducts add another item to the lengthy list of equipment the wing designer is struggling to incorporate inside the wing of the modern multi-engined airplane, and still find room for his primary structure.

Removal of ice from the wings and empennage is not enough. Other serious problems are those of propeller, carburetor, and windshield icing. Were one to list the icing up problems in order of the importance of their solution to safe scheduled airline operation, the order would probably be: (1) induction system (air scoop, duct, carburetor); (2) propeller; (3) wings and empennage; (4) windshield; (5) airspeed head (pitot-static tube).

Induction systems are commonly protected from ice plugging by carburetor air heaters which transfer from the exhaust gases to the incoming air enough heat to prevent the adiabatic expansion, and cooling by gasoline evaporation, from lowering the air temperature to the point where ice would begin to deposit on carburetor venturi, jets, throttle, or other protuberances in the air stream. For the protection of propellers, feed shoes distribute anti-icing fluid from a slinger-ring along the propeller leading edges. Ice is thrown off in small bits before it can cause unbalance or consolidate in large enough pieces to damage the fuselage.

It is doubtful if this method will prove to be adequate for the larger diameter propellers of the future (say 15 ft. diameter). Electric heating of propellers is possible and may be the solution to problems of preventing ice accumulations on the large-diameter, slow-speed propeller.

Powerful windshield wipers, when assisted by liberation of antifreeze, have been successful in keeping the forward windows in the pilot's compartment sufficiently free of ice to allow the pilot clear vision forward. This method, however, has not been an unqualified success. In the search for improvements, hot air heating applied to the interior of a double-glazed windshield has been used with satisfactory results. However, this is complicated, and the search continues for a better system of insuring clear forward pilot vision. Airspeed head openings if plugged with ice render the instrument inoperative. What is more hazardous is a partial blockage, or a build-up of ice on the air speed strut. These will cause a false airspeed reading, of which the pilot may be unaware. Airspeed heads are usually electrically heated where their accurate functioning is of prime importance, as in airliner piloting. This method is entirely successful. (F.T.M.)

DEIONIZATION TIME. **Thyratron.**

DELIQUESCENCE AND WATER ABSORPTION. When a substance absorbs moisture upon exposure to the **atmosphere**, the substance is said to be deliquescent, and the phenomenon is known as deliquescence. At ordinary temperatures the vapor pressure of water varies as shown in the following tabulation.

Temperature, °C.	Water Vapor Pressure, in mm. of Mercury	
	At Saturation	At 50% Humidity
0	4.6	2.3
10	9.2	4.6
20	17.5	8.8
30	31.8	15.9
40	55.3	27.7

If the solution in water of a substance has a lower water vapor pressure than corresponds to that of the atmosphere at the given temperature, water vapor condenses in the solution from the atmosphere until the water vapor pressure of the solution equals the water vapor pressure of the surrounding atmosphere.

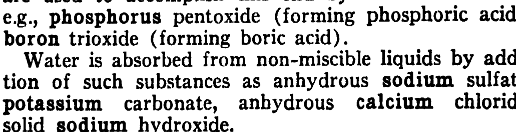
Substances that are ordinarily deliquescent are **sulfuric acid** concentrated, **glycerol**, **calcium** chloride crystals, **sodium** hydroxide solid, **ethyl alcohol** 100%. In an enclosed space these substances deplete the water vapor present to a definite degree. Other substances are used to accomplish this end by chemical reaction, e.g., **phosphorus** pentoxide (forming phosphoric acid), **boron** trioxide (forming boric acid).

Water is absorbed from non-miscible liquids by addition of such substances as anhydrous **sodium** sulfate, **potassium** carbonate, anhydrous **calcium** chloride, solid **sodium** hydroxide.

See **Efflorescence** for the converse phenomenon. (R.K.S.)

DELIRIUM. A mental disturbance characterized by disorientation, **hallucinations**, incoherent rambling speech, excitement and usually extreme restlessness. It occurs with high fever, especially in children, or with the **toxemia** of any severe illness. It is often present in various forms of mental disease and also may result from drugs or abuse of alcohol. Delirium tremens occurs in alcoholics; its chief features are hallucinations, agitation, and tremors of the extremities. It may occur in the chronic alcoholic following a temporary excess or sudden withdrawal of alcohol. It is particularly liable to develop in the alcoholic with **pneumonia**, in **erysipelas**, or following trauma. In uncomplicated delirium tremens the mortality is about 5–15%, pneumonia being the usual immediate cause of death. (R.S.M.)

DELTA. The terminal deposit of river-borne sediment in a lake or bay. So called because of its triangular

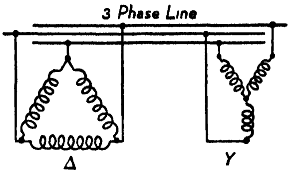


Ideal structure section of a delta T, top-set beds; B, bottom-set beds; F, fore-set beds. (*Modified after G. K. Gilbert.*)

or delta-like ground plan. The cross-section or structure of a typical delta is shown in the accompanying sketch. Except in the case of small deltas only the top-set beds can be observed. In the case of **Paleozoic**, **Mesozoic**, and **Cenozoic** deltas it is extremely difficult to distinguish between the top-set, fore-set, and bottom-set beds, and the ultimate determination that a **sedimentary** formation is of delta origin depends largely on tracing the original source and areal distribution of the sediments, and the presence or absence of marine and terrestrial fossils. (R.M.F.)

DELTA CONNECTION. The Delta connection is one of the two most frequently used ways of connecting a three-phase **alternating-current circuit**. The other is the Y connection. A three-phase machine has three coils. These coils have six ends which must, in some way, be connected to the three wires of a three-phase circuit. The Delta connection, as illustrated in the accompanying figure, has the coils connected at three points corresponding to the three-phase circuit. When

this is compared with the Y connection, it will become apparent that the line voltage in Delta connection equals the coil voltage, and that the line current in Y connec-



Δ-connection and Y-connection compared.

tions equals coil **current.** For a balanced Delta load the line current is $\sqrt{3}$ times the phase (or coil) current. (F.T.M., L.R.Q.)

DELTA RAYS. When various substances are bombarded with **alpha rays,** they are found to give off **electrons,** which sometimes move with great speed, and to which Sir J. J. Thomson has given the name delta rays. The delta electrons are thought to originate in a type of **ionization** of the bombarded substance, though by some it has been held that they are really thermions given off as the result of the very brief and very intense local heating of the body when the alpha particle strikes it. The rays appear to be emitted mostly in directions at right angles to that of the alpha-ray beam. Delta particles are themselves capable of causing ionization, as shown by the cloud tracks produced when alpha particles traverse a gas in a **cloud chamber.** (L.D.W.)

DELUSION. **Hallucination.**

DEMAND. In the nomenclature of economics, demand is the number of units of a commodity which will be purchased at a given price. It is the correlation of desire for the article, and ability to purchase it.

In a narrower technical sense, demand is that number of commodity units a source of supply is caused to produce, manufacture, or otherwise create. The maximum demand is an important index, especially in an industry unable to warehouse its product, and which, therefore, is required to have manufacturing capacity at least equal to the maximum demand. (F.T.M.)

DEMAND FACTOR. With reference to the electric service industry, demand factor is the ratio of a customer's maximum demand to his connected load, i.e., to the sum of the full-load ratings of all the electrical equipment he has connected to the supply line. (F.T.M.)

DEMODULATION. **Detection.**

DE MOIVRE'S THEOREM. De Moivre's theorem is a rather remarkable mathematical result discovered by the French mathematician Abraham De Moivre (1667–1754).

De Moivre's theorem gives any **power** of a **complex number** in polar form:

$$[r(\cos\theta + i\sin\theta)]^n = r^n(\cos n\theta + i\sin n\theta).$$

This formula holds when n is a positive or a negative integer. It also holds when n is fractional, but may then be written in the more general form:

$$[r(\cos\theta + i\sin\theta)]^{1/n} = r^{1/n}\left[\cos\frac{\theta + k\cdot 360^\circ}{n} + i\sin\frac{\theta + k\cdot 360^\circ}{n}\right],$$

where k takes the values of 0, 1, 2, $\cdots$, $n-1$ and where $r^{1/n}$ denotes the principal n^{th} root of r. This formula gives the n, n^{th} roots of any number. (L.L.S.)

DE MOIVRE-LAPLACE THEOREM. Let us consider a **Bernoulli probability function,** p = **probability** of success, $q = 1 - p$ = the probability of failure in a single trial, s = the number of trials, P_x = probability of x successes in s trials, $P_x = {}_sC_x p^x q^{s-x}$. When s is large it is difficult to evaluate P_x directly or to solve such problems as

$$\sum_{x=a}^{x=b} P_x, \quad 0 \leqq a \leqq x \leqq b \leqq s.$$

De Moivre overcame this difficulty by showing that as $s \to \infty$, the **probability function** P_x approaches a **normal** curve with **mean** sp and **variance** spq. Hence

$$P_x \approx \frac{1}{\sqrt{spq}\sqrt{2\pi}} e^{-\frac{(x-sp)^2}{2spq}}$$

or by areas

$$P_x \approx \int_{t_1}^{t_2} \phi(t)dt, \quad t_1 = \frac{x - \frac{1}{2} - sp}{\sqrt{spq}}, \quad t_2 = \frac{x + \frac{1}{2} - sp}{\sqrt{spq}},$$

$$\phi(t) = \frac{e^{-t^2/2}}{\sqrt{2\pi}},$$

the **normal probability function** in **standard units.** Similarly

$$\sum_{x=a}^{x=b} P_x \approx \int_{t_1}^{t_2} \phi(t)dt,$$

$$t_1 = \frac{a - \frac{1}{2} - sp}{\sqrt{spq}}, \quad t_2 = \frac{b + \frac{1}{2} - sp}{\sqrt{spq}}.$$

These approximations improve as s increases, when p and q are nearly equal and are better in the neighborhood of the mean than in the two tails. De Moivre gave additional terms and for greater accuracy the **Gram-Charlier** Type A gives generally as much accuracy as desired. Of course $\sum_{x=a}^{x=b} P_x$ may be found by means of the **incomplete Beta function** which is exact. However, generally the tables do not extend far enough if s is large. In some cases continued fractions possess definite advantages but at the expense of somewhat longer computations. (L.A.A.)

DEMOSPONGIAE. A class of **sponges** (Porifera) of complex structure, including the sponges of commerce and the fresh-water sponges.

The members of this class have siliceous spicules which are never 6-rayed, a spongin skeleton, or a combination of spongin and siliceous matter. Some species have no skeleton. The body plan is of the **rhagon** type.

Three orders are recognized:

Order Myxospongida. Simple sponges without skeletal structures.

Order Tetraxonida. Skeleton siliceous (see **Silicon**), sometimes with spongin. Fresh-water sponges are included in this order with many marine forms

Order Keratosa. Skeleton of spongin fibers. **Spicules** absent. Commercial sponges belong here. (A.W.L.)

DENDRITE. A tree-like crystal formed during solidification of metals or alloys. Dendrites generally grow inward from the surface of the mold, extending branches from a central trunk in a manner resembling a fir tree In alloys, the central portions of a dendritic crystal are richer in higher melting point constituents, while the outer portions consist of lower melting point material

Dendrites in a brass casting (67% copper, 33% zinc) at 25 times magnification. Etched with a solution of $NH_4OH—H_2O_2$. (See *Metallography.*)

which is last to solidify. This form of segregation can usually be eliminated by diffusion during subsequent mechanical working and heat treatment. (See **Neuron.**) (R.H.H.)

DENDROCHIROTA. Holothuroidea.

DENEBOLA. Denebola (β **Leonis**) received its name because of its position in the **constellation** of Leo, the name Denebola being derived from an abbreviation of an Arabic phrase meaning "tail of the lion." In astrology, Denebola is one of the unfortunate stars, portending misfortune and disgrace. (W.K.G.)

DENGUE. "Breakbone Fever" or "Dandy Fever." An acute fever due to a filterable **virus** which is present throughout the circulation for one day preceding and 2 or 3 days following the onset of the disease. It is common in many tropical countries, and sudden outbreaks or epidemics occur in subtropical or even temperate climates. Several years ago there was a serious outbreak in the southern states, particularly in Florida. In 1928 there were widespread outbreaks in Greece and Egypt. In World War II, cases have occurred in Hawaii and New Guinea.

Dengue is transmitted by mosquitoes of the species *Aedes Aegypti,* which have become infected by biting a dengue patient during the first 48 hours of his fever. Twelve days are required for the mosquito to be able to transmit the disease to another human, who in turn becomes ill 4–10 days later. **Yellow fever** is transmitted by the same mosquito, and since both diseases are often prevalent in the same locality, some have speculated that similar organisms are responsible for the two diseases. However, in certain regions of the eastern hemisphere, dengue is common where yellow fever is unknown.

The disease lasts 7–8 days. It is characterized by the sudden onset of an acute fever with chill, severe headache, marked pain in the muscles and joints and profuse sweating. A skin eruption usually appears on the third day; the symptoms rapidly disappear and the patient seems well on the road to recovery. However, 48 hours later the symptoms reappear and last for 36 or more hours. Convalescence is protracted and mental depression is marked. Complications are rare, and the disease seldom causes death. One attack confers immunity for 6 months to several years. There is no specific treatment. The disease can, however, be prevented by anti-mosquito measures. (R.S.M., D.M.H.)

DENSITY AND DENSITOMETERS. The term *density* was introduced into photographic terminology by Hurter and Driffield who were the first to express quantitatively the relationship between the mass of silver in a photographic deposit and its light-absorbing and light-transmitting properties.

An instrument for determining the blackening, or photographic density, of a developed photographic plate or film is known as a densitometer. There is a great variety of types of densitometers, but the underlying principle of all of them is the same. The intensity of the radiant energy from a source which is maintained as nearly constant as is possible, is compared by any of the methods of **photometry** with the intensity of the same radiation after it has passed through the portion of the photographic plate whose density is required.

For the determination of the density of a very small area on a photographic plate, such as the image of a spectral line or a star, the instrument employed is usually referred to as a "microdensitometer." In such instruments the physical type of photometer, e.g., one employing a **photoelectric cell** or a **thermopile,** is frequently employed. (C.B.N., W.K.G.)

DENSITY AND SPECIFIC GRAVITY. The density of a substance is its mass per unit volume, usually expressed in grams per cubic centimeter. The specific gravity of the substance is the ratio of its density to that of water, usually at 4° C., or 20° C., or 60° F., in the same units, and is therefore an abstract number independent of units.

To determine the density of a given substance, it is necessary only to ascertain the volume of a specimen whose mass is known by weighing. This may be obtained from measurements on the dimensions of the specimen, or, in the case of a liquid, by the use of a **pycnometer** or specific gravity bottle For solids a more precise method is to measure the buoyant force, upon the specimen, of a liquid of known density in which it is immersed, or by enclosing it in a specific gravity bottle and determining the volume by displacement. The Mohr-Westphal balance is especially designed to give densities of liquids by the buoyant force on a solid sinker of known volume. The **hydrometer** may also be used for quick determinations of liquid densities. The density of a gas is best obtained by weighing a specimen of it in a large, light bulb of known capacity, concurrently observing the temperature and pressure to which the gas is subjected, much as the pycnometer is used for liquids.

A brief table of densities, all in grams per cubic centimeter, is appended. For gases the densities are at standard temperature and pressure.

Substance	Density	Substance	Density
Air	0.001293	Gold	19.3
Alcohol	0.704	Hydrogen	0.0000899
Aluminum	2.70	Iron	7.86
Carbon dioxide	0.001977	Lead	11.3
Chlorine	0.003214	Mercury	13.55
Copper	8.90	Nitrogen	0.001251
Cork	0.24	Oxygen	0.001429
Gasoline	0.67	Platinum	21.45
Glass	2.4–2.8	Silver	10.5
Glycerine	1.27	Water (4° C.)	0.999973

The term density is also applied to the blackness of the image on a photographic plate or film. (See **Density and Densitometer.**) (L.D.W.)

DENSITY OF AIR. Total mass of air per cc. is the density of air. It is given by the relation

$$\text{density} = \frac{0.0012930}{1 + 0.00367t}\left[\frac{B - 0.378e}{760}\right]$$

where t = Temperature, °C.
B = Barometric pressure expressed in mm. of mercury.
e = The partial pressure of water vapor in the air.

Air density at standard conditions of 0° C. and 760 mm. of Hg is 0.0012930 grams per cc. of air free from water vapor. (P.E.K.)

DENSITY RANGE. A term commonly used in color photography to denote the range of densities found in a given negative or positive. Measures of density to obtain the range are generally, although not always, made on achromatic areas. The difference between the maximum and minimum densities in a particular negative or positive is its density range. Under special conditions a measure of the density range gives the same information as **gamma** but this correlation must not be assumed to hold unless complete sensitometric data in any individual case show it to be true. (H.C.C.)

DENTARY APPARATUS. Aristotle's Lantern; Tooth.

DENTINE. Tooth.

DENTITION. The form and arrangement of the teeth in **vertebrates.** Teeth are so intimately related to the food that they are involved in the fundamental adaptations of the animal. In connection with the study of the many adaptations of teeth, terms have been coined which apply in some cases either to the **tooth** itself or to the entire dentition, while others apply to the dentition in general.

The primitive form of tooth is apparently that of the **sharks,** which has a principal sharp flattened point and in some cases fairly prominent lateral points. These teeth are arranged in several rows and are renewed as needed. In other fishes and in the amphibians teeth are also developed in large numbers and in some forms occur elsewhere in the mouth than on the jaws. They are named for the part of the skull with which they are associated, as the vomerine teeth.

In the **reptiles** and **mammals** the simpler condition of a row of teeth along each jaw prevails. The teeth may be entirely conical as in the reptiles or of various types, as in the mammals, and may be indefinitely renewable or limited to one or two sets. Where teeth are of more than one kind the dentition is said to be heterodont. The forms of teeth include the sharply conical canines, the sharp-edged cutting incisors, and the broad grinders, which include premolars and molars. Renewal is unlimited in the reptiles but in the more highly specialized mammals only one or two sets appear normally. Monophyodont dentition consists of one set and diphyodont includes a temporary set of milk teeth which is replaced by a set of permanent teeth, as in man.

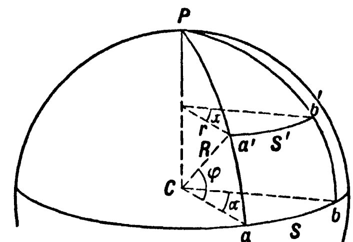
The numbers of teeth of different kinds are expressed in a dental formula as a distinctive characteristic of mammals. In this formula the teeth of one-half of each jaw are listed in this order: incisors, canines, premolars and molars, and those of the upper jaw are placed above those of the lower jaw. Thus the dental formula of man is 2123/2123 and that of the woodchuck is 1023/1013. The zeros in the latter formula indicate the absence of canines.

The position of the teeth in the jaw is also sometimes indicated by a special term. When placed along the edge of the jawbone the dentition is said to be acrodont, and when placed along the inner margin, pleurodont. (A.W.L.)

DENUDATION. Cycle of Erosion.

DEPARTURE. Any **course** and distance covered by a ship may be resolved into two components at right angles to each other. One of these components will be parallel to a **meridian** while the other will be along a parallel of **latitude** and is known by the term departure. If the lengths of these components are expressed in **nautical miles** the component along the meridian may be immediately converted into difference of latitude because a minute of arc of latitude is practically equal to one nautical mile. The component along the parallel of latitude, expressed in **nautical miles** and referred to as easting or westing, is known as the departure.

For the solution of various problems in **dead reckoning** and the **sailings** it becomes necessary to convert departure into difference of **longitude.** The accompanying figure illustrates the problem. In the figure



Departure.

we have S' a departure measured along the parallel of latitude ϕ between the meridians $Pa'a$ and $Pb'b$. The arc, S, of the **equator** represents the difference of longitude corresponding to the departure S'. Planes are passed through S' and S perpendicular to the axis of the earth, PC, and radii are drawn in these planes to include the angles subtended by S' and S. Call R the radius of the earth and r the radius of the arc S'. The angles subtended by S and S' must be equal and we have at once $S/R = S'/r$. By the definition of latitude (assuming the earth as spherical) we have the plane angle $aCa' = \phi$ and, from the definition of the trigonometric functions, $R/r = \sec\phi$. Therefore we have $S/S' = R/r = \sec\phi$; or $S = S'\sec\phi$. Since S' is expressed in nautical miles, which are practically equivalent to a minute of arc on the equator, we have at once $S = S'\sec\phi$ as the difference in longitude corresponding to the departure S'; the difference in longitude being thus expressed in minutes of arc. (W.K.G.)

DEPENDENT SYSTEMS OF LINEAR ALGEBRAIC EQUATIONS. Linear Algebraic Equations, Systems of.

DEPENDENT VARIABLE. Functions.

DEPHLEGMATOR. A partial condenser used in distillation. It also acts as a partial theoretical plate. (See **Distillation.**) (D.E.M.)

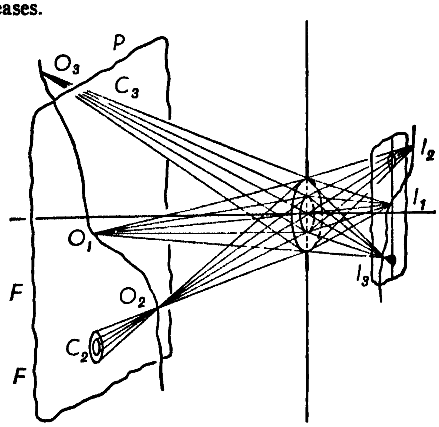
DEPRESSED EQUATION. Polynomial Equations.

DEPRESSION. A region over which atmospheric pressure is lower than surrounding regions. A depression, of necessity, has cyclonic winds. (See **Cyclone.**) (P.E.K.)

DEPTH OF FIELD. In photography the term depth of field refers to the distance over which satisfactory definition is obtained when the lens is in focus for a certain distance. If, for example, a lens is in focus for an object at a distance of 25′ and the definition is satisfactory on objects from 20–40′, the depth of field extends from 20–40′. Depth of field is frequently but incorrectly termed depth of focus, which is the range

of image distances corresponding to the range of object distances covered by the depth of field.

The depth of field depends upon: 1. The standard adopted for "satisfactory" definition. 2. The distance of the plane on which the lens is in focus. 3. The focal length of the lens. 4. The relative aperture (f/number). So far as the last three are concerned we may note (1) that the depth of field increases with the distance of the plane on which the lens is in focus and (2) that it becomes less as the focal length or (3) as the aperture increases.



Let O_3, O_2, O_1 represent an object, parts of which are at different distances from the lens L. Suppose the lens to be focused on O_1, a point image I_1 will be formed on the focusing screen, or sensitive plate. With the focusing screen, or the sensitive plate, at this point it is clear that the image of O_2 is formed at I_2 *behind* the screen and that of O_3 at I_3 in *front* of the screen. In other words, the position of the image point varies with the distance of the object point and the lens cannot produce a point for point image upon a plane surface, such as the sensitive film, unless the subject itself is a plane. When this is not the case, the image of points nearer or further from the lens is a circular disk rather than a point.

Any disk, however, will appear to the eye as a point if the viewing distance is sufficiently great. At a distance of 10″, for example, a circle with a diameter of 1/100″ appears as a point to the average eye. On an angular basis this corresponds to about 2 minutes of an arc.

Since any unsharpness in any part of the negative is increased when an enlargement is made, the disk, or circle of confusion, in an enlargement is equal to the diameter of the disk in the negative multiplied by the degree (times) of enlargement. Thus, if the largest circle allowable for sharp definition is assumed to be 1/100″ and the print is a 5× enlargement, the maximum diameter of the circle of confusion in the negative is 1/100 × 5 or 1/500″ and the depth of field should be calculated accordingly.

If it is assumed that the viewing distance is the distance at which the proper perspective is obtained, i.e., a distance equal to the focal length of the lens, then the circle of confusion can be expressed as a fraction of the focal length of the lens. The value generally used is 0.00058 or 1/1720 of the local length.

If u = distance focused on,
θ = angular size of circle of confusion (1/1750 of the focal length),
r = effective diameter of lens or the focal length divided by the f/number,

then the nearest point sharply defined in front of the plane in focus is

$$\frac{u^2 \tan\theta}{r + u\tan\theta}$$

and the greatest distance beyond the plane in focus is

$$\frac{u^2 \tan\theta}{r - u\tan\theta}$$

Tables of depth of field are included in most camera manuals and in reference books. (C.B.N.)

DERIVATIVE OF A FUNCTION OF ONE VARIABLE. The rate of change of a function is expressed by the derivative of the function.

Let $y = f(x)$ be a given **function** of one **variable** and let x_1 be a chosen value of x, and let Δx be an increment of x to be added to x_1, then Δy will denote the corresponding increment of y:

$$\Delta y = f(x_1 + \Delta x) - f(x_1).$$

Form the increment ratio $\Delta y/\Delta x$:

$$\frac{\Delta y}{\Delta x} = \frac{f(x_1 + \Delta x) - f(x_1)}{\Delta x}.$$

Let $\Delta x \to 0$, then $\Delta y/\Delta x$ will usually approach a **limit** which is called the derivative of y with respect to x at the value $x = x_1$. Hence:

The derivative of a function $f(x)$ is the limit approached by the ratio of the increment of $f(x)$ to the increment of x when the increment of x approaches the limit 0.

The process of finding the derivative of a function $y = f(x)$ is called differentiation.

The derivative of $y = f(x)$ with respect to x is denoted by various symbols; sometimes $D_x y$ is used, sometimes $\dfrac{dy}{dx}$, or $f'(x)$, or y'.

If $\lim\limits_{\Delta x \to 0} (\Delta y/\Delta x)$ is formed at the point $x = x_1$, it is called the derivative at $x = x_1$; but if the limit is taken for the general point x, the result is sometimes called the derived function of $f(x)$.

The rate of change of any function $f(x)$ with respect to the independent variable x is defined as the derivative $D_x y$ or dy/dx.

Special interpretations of the derivative are:

1. As the **slope** of a curve: If x and y represent rectangular coordinates of a variable point, and if a function $y = f(x)$ represents a curve, then the slope of the tangent to the curve at a point $x = x_1$ is represented by the value of the derivative of $f(x)$ at $x = x_1$.

2. As the speed of a moving particle: If s denotes the distance traversed by a particle moving in a straight line in time t, then a function $s = f(t)$ represents the law of motion, and the derivative of $f(t)$ at $t = t_1$ represents the speed of the particle at the instant t_1.

For a function $y = f(x)$, the ratio $\dfrac{dy}{dx}/y$ is called the relative rate of increase of y with respect to x; the product of this by 100 is sometimes called the percentage rate of increase

If $f'(x)$ is positive throughout an interval (a, b), then $f(x)$ continually increases as x increases from a to b. If $f'(x)$ is negative throughout (a, b), then $f(x)$ continually decreases as x increases from a to b. (L.L.S.)

DERIVED CURVES. Higher Derivatives.

DERIVED FUNCTION. Derivative.

DERMAPTERA. The earwigs. An order of **insects** made up of species whose forewings, when present, are short leathery wing covers, and whose abdomen bears a pair of appendages like the jaws of a forceps at the tip. The common name is based on the supposition that they enter the ears of human beings. They are plant-eating, insect-eating, and probably in some species scavengers. (A.W.L.)

DERMATITIS. An irritation or inflammation of the skin due to infection, allergic reactions to a variety of agents, **drugs**, heat, cold, **x-rays**, or radium. Derma-

titis may also be seen in metabolic and deficiency states. (D.M.H.)

DERMATOLOGY. The study, diagnosis, and treatment of the skin and its diseases. (D.M.H.)

DERMESTID. Insecta, Coleoptera. Any of the small **beetles** of the family Dermestidae, including the **buffalo carpet moth.** They damage clothing, woolen articles, and museum specimens. (A.W.L.)

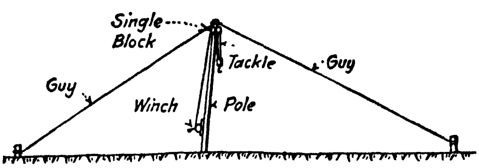
DERMIS. 1. The corium or inner layer of the **skin** of vertebrates. 2. The inner layer of the **cuticula** of insects. (A.W.L.)

DERMOLITH. A term proposed by T. A. Jaggar in 1917 for ropy, wrinkled or **pahoehoe** type of basic lava, such as occurs in the volcanic islands of Hawaii. (R.M.F.)

DERMOPTERA. An order of mammals containing only the **flying lemurs** of the Malayan region. They differ from other mammals in dentition. Like the flying squirrels, they have folds of skin along the sides which support them in the air. Also called cobego, kaguan, and other names. (A.W.L.)

DERRICK. A derrick is a device for lifting heavy objects. It is used in all types of construction work when heavy material must be raised into position. Derricks are used extensively in structural steel erection.

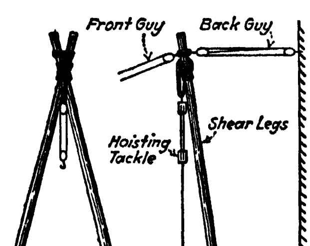
The simplest form of derrick is the gin pole which consists of a vertical or nearly vertical mast held in



Gin pole. (*Underwood, Standard Construction Methods, McGraw-Hill Co.*)

position by at least four twisted wire cables or ropes known as guys. A pulley or some other form of hoisting tackle attached to the top of the mast completes the equipment. The gin pole is frequently used in the erection of steel frames for small buildings when all of the members can be placed in position without moving the derrick, as a whole, vertically, to some point on the frame.

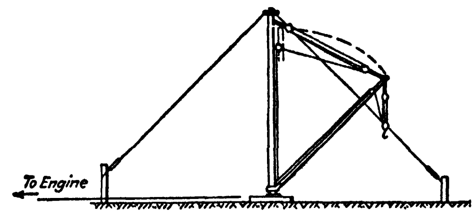
The shears derrick is essentially a gin pole derrick which is constructed in such a manner that only two



Shears. (*Underwood, Standard Construction Methods, McGraw-Hill Co.*)

guys are necessary. The "mast" is a V-shaped frame made of two poles which may, in some cases, be connected by transverse bracing. Since this form gives it lateral stability only two guys are required. This derrick is often used for the erection of heavy machinery which is lifted by means of hoisting tackles connected to the "mast" at the point of intersection of the poles.

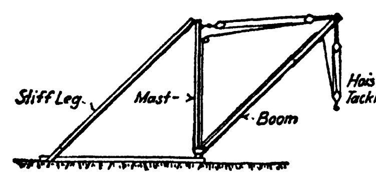
The guy derrick is made up of a **boom** and a mast that are connected at the top by a **cable** which allows



Engine-operated guy derrick. (*Underwood, Standard Construction Methods, McGraw-Hill Co.*)

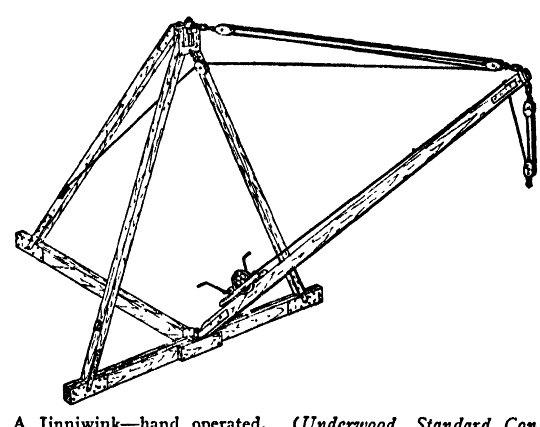
the boom to be raised or lowered. The mast, which is longer than the boom, is held firmly in a vertical position by guys although the derrick, as a whole, may rotate through a horizontal angle of 360°. The load is applied to the boom by means of another cable which may be used to raise or lower the load without moving the boom in a vertical plane. This type is used in the erection of large steel building frames since it can be readily set up at any floor level and has a large range of movement.

The stiff-leg derrick is similar to the guy derrick except that it does not require guy wires or ropes to



Engine-operated stiff-leg derrick. (*Underwood, Standard Construction Methods, McGraw-Hill Co.*)

support the mast and the boom has a horizontal swing of only about 240°. The mast is supported by struts set at right angles to each other. The lifting action is the same as that for the guy derrick.



A Jinniwink—hand operated. (*Underwood, Standard Construction Methods McGraw-Hill Co.*)

The A-derrick or Jinniwink is a modification of the stiff-leg derrick. It is used for lifting comparatively light loads. (C.W.C.)

DESCARTES' RULE OF SIGNS. If in passing from one coefficient of a **polynomial equation** to the next, there is a change of sign from plus to minus or from minus to plus, this is called a variation of sign; a succession of two like signs, either both plus or both minus, is called a permanence of sign.

Descartes' rule is: The number of positive **roots of a** polynomial equation $P(x) = 0$ with real coefficients **is**

not greater than the number of variations of sign in the polynomial $P(x)$, and the number of negative roots is not greater than the number of variations of sign in the polynomial $P(-x)$. (L.L.S.)

DESCRIPTIVE GEOMETRY. The theory of graphic representation, invented and developed by Gaspard Monge, 1795. Descriptive geometry deals with the exact representation of objects composed of geometrical forms and of the graphical solution of problems involving the space relationship of these forms. (H.C.H.)

DESCRIPTIVE STATISTICS. Descriptive statistics is mainly concerned with the techniques of tabulation, collection, summarizing of data, and also the calculation of measures which adequately describe a **sample.** It is not concerned with the theory of statistical inference. (L.A.A.)

DESENSITIZING. In 1920 Dr. Luppo-Cramer discovered that bathing an exposed film or plate in phenosafranine reduced its sensitiveness to light to such an extent that even high-speed orthochromatic materials may be developed without danger of fog in a bright yellow or orange light. With panchromatic materials phenosafranine was less effective but other desensitizers for use with panchromatic materials were soon found.

The number of desensitizing substances is fairly large. In addition to phenosafranine the list includes picric acid, aurantia, chrysoidine, methylene blue, the oxidation products of several developers and mercuric cyanide. Many of these are unsatisfactory in practice. Some stain the gelatin, others produce fog and still others partially destroy the latent image. The best known desensitizers are phenosafranine, pinakryptol green and pinakryptol yellow, the two last being products of the I.G. Farbenindustrie.

Desensitizers are used either as a preliminary bath prior to development or as an addition to the developer. Usually the desensitizer is more effective when added to the developer. Some, however, cannot be used in the developer; either the desensitizer is precipitated or it is destroyed by the sulfite contained in the developer.

Little is known of the chemical reactions involved in desensitizing. Luppo-Cramer pointed out that most desensitizers are oxidizers and suggested that the oxidizing power of a desensitizer is sufficient to prevent the formation of a latent image, except upon greatly increased exposure to light, but is not strong enough to attack the latent image already formed. The evidence available, in general, supports this hypothesis. (C.B.N.)

DESMINE. Stilbite.

DESQUAMATION. The shedding of the superficial cells of the skin in scales or large pieces, a phenomenon which occurs in certain diseases, notably **scarlet fever.** (R.S.M.)

DESTRUCTIVE DISTILLATION PRODUCTS. **Coal, wood,** bone, **petroleum** are the industrial raw materials most commonly subjected to the process of destructive distillation. In this process the materials are heated to various degrees of temperature without access of air (pyrolysis) but with provision for recovery and collection of the products desired. The reactions are complex due in large part to the complexity of composition of the material treated. For the treatment of petroleum see **Hydrocarbons.** The destructive distillation of coal, wood, bone and carboniferous shale will be discussed under the topics (1) Raw material, (2) Conditions of temperature and time of treatment, (3) Products.

Coal, Destructive Distillation. 1. Destructive distillation of coal is conducted primarily to produce coke or **coal gas,** and secondarily for coal tar, **benzene** and **toluene** from the coal gas and coal tar, and **ammonia** from the coal gas and water condensate. Bituminous coals are found to be most suitable for this purpose. These coals have a fuel value of 12,000 to 15,000 B.T.U. per lb., that is 24 to 30 million B.T.U. per short ton (2000 lbs.). Reports of analyses made by the United States Bureau of Mines on samples of coking coal as received from 23 coal fields of the United States show:

Moisture	1–10%
Volatile matter	25–38
Fixed carbon	71–47
Ash	2.5–9
Nitrogen	1.4–2
Sulfur	0.5–1.5

From such coals there would be obtainable:

Furnace coke	60–80%	of the weight of coal
Coal gas	2700–3500	B.T.U. per lb. of coal
Surplus after heating retorts	1600–2100	B.T.U. per lb. of coal
Coal tar	6–12	gals. per ton of coal
Benzol	1.5–4	gals. per ton of coal
Nitrogen		
As ammonium sulfate	17–25	lbs. per ton of coal
As sodium cyanide	1.8 (appr.)	lbs. per ton of coal

2. Conditions. Since coal and coke are poor conductors of heat, it is necessary that the thickness of the layer heated be such that the coking temperature, at the places in the charge that are most distant from the source of heat, shall be attained in an economical period of time. In the history of the industry the horizontal width of retort has been gradually diminished from 24 to 22″ to 12 to 14″. Since both of the vertical side walls are heated to the desired high temperature, the heat must traverse from 12 to 11″ (older types) to 6 to 7″ (newer types). The thinner retorts result in a much shorter time—as short as 10 hours—for coking a charge. A further result is that the coke near the heated walls is subjected to a high temperature for a shorter period of time than formerly. The length of retort has been extended from 20′ (older types) to 40′ (newer types). The length is determined by mechanical considerations of removing the charge economically. The height has been increased from 6′ (older types) to 13′ (newer types). The retorts are charged from the top, and discharged by pushing the coke out of one end by a pusher entering the other end.

The heat is supplied by burning gas in flues between each retort, and batteries containing up to 90 retorts are in use. In 1919 the United States Bureau of Standards reported tests made in Koppers retorts. Temperature of 1225° C. maximum to 1200° C. minimum were observed in the heating flues and the operating temperature is close to these temperatures; in the center of the charge, and at distances of about 2′ from the bottom and the top of the retort 1010° C. and 980° C., respectively, in 10.5 hours—the coking time in retorts about 14″ thick.

The changes in composition of gas with time of heating of a given coal are reported by Bacon and Hamor (1922) from which the following is selected or calculated:

Hours Coal Carbonized	Methane	Hydrogen	Ethylene	Carbon Monoxide	Carbon Dioxide	Benzene	B.T.U. per cu. ft.
2	36.7	42.5	4.0	0.9	3.3	1 8	605
4	34 5	48 8	3.1	2 9	2.3	1 1	570
6	33 6	50 1	2 8	3.0	2.2	1.0	560
8	33 7	53 8	2.5	3 4	1.4	0 6	560
10	31 2	47.1	1.8	2 8	2.3	0 4	480
12	33.4	50 7	1.9	4 2	1.5	0.4	525
15	33 2	53 4	1.8	3 9	1 9	0.3	525
19	26 1	55 8	1.2	4 7	1.1	0.0	450

(24 hours time of carbonization. The amount of gas evolved at each stage of heating is not reported.)

The recent types of retorts use **silica** brick for the walls. These have been found most satisfactory on the basis of thermal, mechanical and economic considerations. Two-thirds of the heat consumed passes through the walls of the retort to the charge, and one-third is lost from the flues, the total actually required being about 1225 (1100–1400) B.T.U. per lb. of coal carbonized. Beehive ovens, in which coal was coked with loss of other products, and the small retorts used specially in making coal gas have been largely displaced by by-product recovery retorts as described.

3. Products. *a.* Coke. The quality of coke depends upon the kind of coal used, the amount of moisture present in the coal, the fineness of the coal (the coal is pulverized to a fineness approximately 85% passing through ⅛" mesh), the width of the retort, and the temperature of the walls of the oven. The time of coking is in practice determined by the above factors. The ash present in the coal remains in the coke, and the percentage of ash is therefore higher in the coke than in the coal in proportion to the loss of volatilized matter. For metallurgical purposes the **sulfur** and **phosphorus** contents of the coke are considerations. As to the sulfur, this is present in three forms in the coal, namely, as organic sulfur compounds (from 0.5 to 2% of the coal), **iron** disulfide (pyrite) (from 0.1 to 8%), and **sulfates.** About two-thirds of the total sulfur is retained in the coke, and one-third removed in the volatilized matter. Data regarding **phosphorus** is regularly examined by some operators. **Nitrogen** exists in coal in two forms, namely, **amino** nitrogen (group $—NH_2$) and nitrogen-ring compounds (for example, **pyridine** ). The total nitrogen in coal is 1.4 to 2%, of which 40 to 50% remains in the coke (possibly as a nitride of **carbon**), 18% is recovered from the volatilized matter as **ammonia,** 3% as pyridine and 1% as **cyanide,** while 25–30% escapes as free nitrogen in the gas. The supporting or crushing strength of coke is an important consideration for metallurgical purposes. *b.* Coal gas. The composition at various stages of heating, and the surplus amount after heating the retorts have been noted. **Ammonia** is recovered by passing the gas through water and then distilling the solution, and the **benzene** and **toluene** by passing the gas through a non-volatile absorbing oil and then distilling the solution. The benzene-toluene distillate makes up 90–95% of light oil, so called, the remaining 10 to 5% coming from the coal tar by distilling up to 170° C. **Sulfur** compounds are removed by passing the gas through layers of hydrated **ferric** oxide spread over a large surface such as wood shavings, or by passing the gas through a solution of **sodium** carbonate. *c.* Light oil. The light oil above mentioned, furnishes when distilled approximately the following materials and amounts:

	Gallons per Ton of Coal Carbonized
Pure benzene..................	1.6 to 2.0
Pure toluene..................	0.4 to 0.6
Xylenes and light solvent naphtha.	0.4
Unsaturated hydrocarbons........	0.3
Heavy hydrocarbons and naphthalene..................	0.25
Wash oil, for benzene absorption from coal gas................	0.35

d. Coal tar. Upon distillation, coal tar furnishes, in addition to the above-mentioned light oil, up to 170° C. (0.2% of coal tar), approximately 10% of its weight distilling between 170 and 230° C. (one-third **phenol,** two-thirds **cresylic acid**), 10% between 230 and 270° C. (**anthracene** oil), and 55% pitch at 350° C. When the distillation is conducted to 1200° C. about 17% coke or retort carbon remains. (See **Coal Tar Products and Intermediates.**)

Wood, Destructive Distillation. 1. Destructive distillation of wood is conducted primarily to produce charcoal, **acetic acid** or **methyl alcohol** and secondarily for wood tar. Certain deciduous or hard woods have been found most suitable for this purpose. Freshly cut or green wood usually contains about 60% water calculated on the weight of dry wood but this may reach as high as 100%. Dry wood is mainly lignocellulose with little ash.

ANALYSES OF SAMPLES OF WOOD DRIED IN OVEN AT 105° C.

Kind of Wood	Cellulose	Lignin	Ash
Redwood...........	48 5%	34.2%	0.2 %
Western yellow pine..	57.4	26.7	0.45
Longleaf pine.......	58 5	..	0.4
Western white pine..	59 7	26.4	0.2
Sugar maple........	60 8	....	0.4
Douglas fir.........	61.5	....	0.4
White spruce......	61 9	..	0.3

The United States Forest Products Laboratory, Madison, Wisconsin, has conducted extensive researches in connection with wood, its treatment, and its uses. Carbonization of wood in piles partially covered with earth or in kilns where by-products are not recovered has been largely displaced by by-product recovery retorts. The production of acetic acid from **acetylene,** of **acetone** from acetic acid and from starch, and of methyl alcohol from **carbon monoxide** and **hydrogen** has been instrumental in furnishing severe competition for the wood distillation industry.

2. Conditions. Klason (1908–10) reported very little decomposition of wood by heating rapidly to temperatures below about 250° C. But chemical changes having notable effects on the strength of wood occur even below 100° C. when wood is thus exposed over a long period of time. Destructive distillation begins at 250° C., is exothermic (i.e., evolves heat) at 280° C., and is finished at about 350° C., when practically all of the acetic acid, wood alcohol and wood tar have been evolved. Above 350° C. the charcoal decomposes into gas and tar, leaving about 30% charcoal residue. It is interesting to note that **cellulose** forms no methyl alcohol upon destructive distillation. High vacuum rapid distillation of wood yields 44% wood tar, transparent, of light color and 20% charcoal; in contrast the yield when heated 14 days at atmospheric pressure is 2% wood tar, dark, and 40% charcoal.

The yield of materials upon the destructive distillation of certain hard woods is as follows:

Kind of Wood	Acetic Acid	Methyl Alcohol	Wood-tar	Char-coal
Beech............	6.0%	2%	10%	41%
Maple...........	5.5	2	11	40
Ash..............	5 0	2	10	41
White oak........	4.5	1.5	7	47

Coniferous or soft woods, upon destructive distillation, yield characteristic wood oils and wood tars; the recovery is complete from the contained volatile oils, about 75% complete from the contained rosin and slight from the fiber of the wood.

About 50% of wood ash is **potassium carbonate.**

3. Products. *a.* Charcoal is used as **fuel** and a reducing agent in metallurgy, where its low ash content and the absence of sulfur and phosphorus are important considerations. Its porosity is great, and crushing strength low. *b.* Wood gas. The composition of the gas evolved when wood is subjected to destructive distillation is of no commercial value. It consists of about 60% **carbon dioxide,** 30% **carbon monoxide,** 3% each **hydrogen** and **methane,** and about 8000 cu. ft. are obtained per cord (128 cu. ft.) of wood, that is, about 240 cu. ft. per 100 lbs. of wood. The gas (about 135 B.T.U. per cu. ft.) is burned to furnish heat to the retorts. *c.* Water condensate. In this is contained the **acetic acid,** wood **alcohol** (methyl alcohol to acetone in the ratio of about 100 to 8 parts by weight), other **ketones,** some **acetaldehyde** and ill-smelling oils. The amount of crude pyroligenous acid, so called, is from 200 to 250 gals. per cord of wood. Crude wood alcohol is obtained by fractional distillation, either with or without previous neutralization of pyroligneous acid, and the acetic acid then recovered by direct fractional distillation or by evaporation of the calcium acetate liquor. *d.* Wood tar. From hard woods 7 to 10% of the weight of the wood, and from pine about 14%. The tar is steam distilled to recover the acid contained. The residue from this treatment is either burned as fuel for the retorts or distilled for various fractions of wood oils, wood tar, creosote (boiling point 200 to 220° C.), and wood tar pitch 50 to 65%.

Bone, Destructive Distillation. 1. Bones, after removal of fat, consist of the two-thirds inorganic bone material, mainly **calcium** phosphate (56% calcium phosphate, 8% calcium carbonate, 1% each calcium fluoride and **magnesium** phosphate), and one-third organic bone material (osseine, **nitrogen**-containing). 2. Conditions. When subjected to destructive distillation there is formed, gas, water condensate, bone oil, and bone charcoal (bone black) residue. 3. Products. *a.* Gas contains **ammonia.** *b.* Water condensate contains **ammonium** carbonate, sulfide, thiocyanate and cyanide. An impure grade of ammonium sulfate may be obtained. *c.* Bone oil, 3 to 5% of the weight of bone, is dark brown to black, of offensive odor, and begins to distil when heated to 80° C. **Pyridine** (C_5H_5N, boiling point 115° C.) is present in the fraction collected below 120° C. and **pyrrole** (C_4H_5N, boiling point 131° C.) in the fraction below 150° C. Pyridine is recovered by separation as the picrate. **Quinoline** (C_9H_7N, boiling point 238° C.) is also obtainable. *d.* Bone charcoal (bone black) consists of the **calcium** phosphate ash of bone impregnated with the residual carbon (10% carbon and 1% nitrogen). This material is used in decolorizing solutions, especially of raw sugar, on account of its adsorptive power for such colored materials, and as a black paint pigment.

Carboniferous Shale, Destructive Distillation. 1. Carboniferous shale, representing one of the greatest reserve supplies of fuel material, occurs in certain regions, for example, Colorado, in vast quantities. 2. Conditions. These have been extensively investigated and yields of 64 gals. (slightly more than 1 5 barrels) per ton of shale are reported. Some 1500 tests were made by R. D. George (1921) of the Colorado Geological Survey. S. D. Kirkpatrick has contributed a series of articles on the subject (Chemical and Metallurgical Engineering, 1924). J. H. Ginet (1923) reported cost of 87 cents per ton of shale, ⅔ of which is cost of mining. The refined products obtainable from Colorado crude shale oil are stated to be as follows: 3. Products. *a.* Gasoline, 15–17% of the crude shale oil, *b.* Kerosene, 30–32%, *c.* Gas oil, 18–26%, *d.* Light lubricating oils, 15–18%, *e.* Heavy lubricating oils, 10–12%, including paraffin wax. Valuable contributions have been made by the Colorado School of Mines and the United States Bureau of Mines. (R.K.S.)

DETECTION. This is the process of separating the intelligence from the **carrier** upon which it was modulated for transmission by radio or wired **carrier.** (See **Modulation.**) For the detection of amplitude modulated signals some sort of rectification must be used since the rapid alternations back and forth of the radio signal are too fast for the loud **speaker** to follow, and even if it did follow them the ear could not respond. Among the earliest radio detectors were various **crystals** such as galena, silicon and silicon carbide. These materials, when properly mounted, will pass current in one direction and not in the other, so by impressing on them the modulated signal they may be made to serve as detectors. The resulting current is a pulsating d.c. which varies in magnitude with the amplitude of the modulation on the original carrier. Crystals are no longer used for ordinary radio reception but are widely used for ultra high frequency detection where the capacitance of the vacuum tube is too high. For radio reception the most common detectors are vacuum **tubes** and at present only two types of detectors are used to any extent. These are the bias detector which uses a grid-controlled vacuum tube and the diode detector which uses a simple diode. Of these the diode is preferable since it is more linear, can handle higher signals without distortion and is suitable for **avc.** On the other hand the bias detector is more sensitive. Figure 1 shows a typical diode detector circuit. The modulated signal is impressed through the coupling **transformer** from a preceding circuit. Current flows through the diode only when its plate is more positive than its cathode, hence it rectifies the signal. This current charges up the **condenser,** which in turn discharges through the resistor when the diode is not passing current. The condenser does not completely discharge but has a voltage across it similar to that shown in Fig. 1*b*, while Fig. 1*a* shows the impressed modulated carrier. It is seen that the voltage across the condenser follows the modulation closely, and by adding additional condenser-resistance units even the slight ripples shown on it may be removed. This voltage may be coupled to the **grid** of an audio amplifier tube and further amplified before being impressed on the **speaker.** The bias detector uses a grid-controlled tube and is biased to or nearly to **cut-off.** Fig. 2 shows a circuit. A signal impressed upon the grid causes plate current to flow only when the signal is positive and hence the plate current flows in pulses. By means of the filter shown in the plate circuit this is smoothed out until it is a reproduction of the original audio wave.

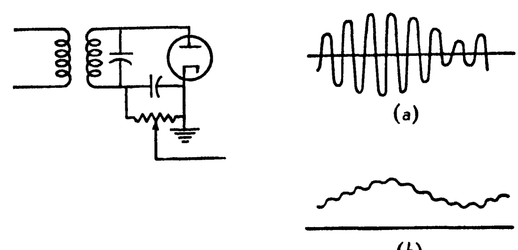


Fig. 1. Diode detection.

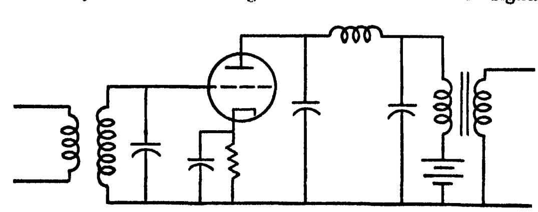

Fig. 2. Bias detector.

Carrier transmission in telephone practice, while using the conventional vacuum tube detectors in several types, uses a copper oxide rectifier in the more modern systems. These rectifiers convert the modulated carrier into a varying d.c. which follows the modulation and which may be separated easily by a transformer into the d-c and audio-frequency components. These oxide units are not sufficiently free from distortion to be suitable for radio work, but are highly satisfactory for telephone service.

In the reception of continuous wave radio signals a heterodyne detector is often used. For such signals to be audible they must be beat with another signal to produce an audible frequency since they have no modulation and hence, even if detected by the usual means, cannot produce a varying output signal. When the continuous-wave radio signal is mixed in a vacuum-tube circuit with a locally generated signal which differs in frequency by some audio amount from it, the resultant output of the tube contains various component frequencies. Among these is one equal to the difference between the two frequencies mixed in the input. By proper adjustment of the frequency of the local signal this difference can be made any value desired and is usually from 500 to 1000 cycles. This gives a pleasing tone for the output. Such reception is called heterodyne detection. A somewhat similar process is used in the first detector of the **superheterodyne** receiver where the difference is made fairly high (this is the intermediate frequency and is always well above the audible range). When the heterodyning signal is generated by the detector serving as an **oscillator** at the same time it is often called autodyne detection.

For frequency modulation detection see **Discriminator.**
(L.R.Q.)

DETECTOR. Detection.

DETERGENTS. Surface-Active Compounds.

DETERMINANTS. A determinant is a certain type of mathematical expression which plays an important part in the study of systems of linear equations and related topics. Determinants were first introduced by the German mathematician and philosopher G. Leibnitz (1646–1716).

A determinant of the second order is denoted by a symbol as

$$\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix},$$

and is defined as representing the expression $a_1b_2 - a_2b_1$.

A determinant of the third order is denoted by a symbol as

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix},$$

and is defined by the expression

$$a_1b_2c_3 + a_2b_3c_1 + a_3b_1c_2 - a_1b_3c_2 - a_2b_1c_3 - a_3b_2c_1.$$

A determinant of the n^{th} order is defined as follows:

Take a set of n^2 numbers, called elements, and arrange them in the form of a square array, with n columns and n rows, thus:

$$\begin{matrix} a_1 & a_2 & a_3 \cdots a_n \\ b_1 & b_2 & b_3 \cdots b_n \\ c_1 & c_2 & c_3 \cdots c_n \\ \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots \\ l_1 & l_2 & l_3 \cdots l_n, \end{matrix}$$

where the letter indicates the row and the subscript the column in which any particular element occurs.

(1) With the elements of such an array form all products that can be formed by taking as factors one element and only one from each row and from each column of the array.

(2) In each product arrange the factors so that the letters are in the same order as in the alphabet and then count the inversions of the subscripts. If their number is even (or zero), give the product the plus sign; if odd, the minus sign.

(3) Take the algebraic sum of all these plus and minus products, and represent it by the array itself with vertical bars at either side of it, thus:

$$\text{(a)} \qquad \begin{vmatrix} a_1 & a_2 \cdots a_n \\ b_1 & b_2 \cdots b_n \\ \cdots & \cdots \\ l_1 & l_2 \cdots l_n \end{vmatrix}$$

The expression determined by (3) is called the determinant of the array, and it is denoted by the symbol (a). When there are n rows and n columns, the determinant is said to be of the n^{th} order.

By an inversion in the preceding definition, we mean any case in which a larger subscript precedes a smaller one when the letters are arranged in their natural order.

This definition includes those given in the preceding for the determinants of the second and third orders.

The diagonal of elements $a_1, b_2, c_3, \cdots, l_n$ is called the principal diagonal of the determinant.

The number of terms in the expression which defines the determinant of the n^{th} order is $n!$

The product of all the elements $a_1, b_2, \cdots, l_n$ lying in the principal diagonal is called the principal term. All the other terms can be formed in order from the principal term by permuting the subscripts in all possible ways.

Some of the principal properties of determinants are the following:

1. The value of a determinant is not changed if its corresponding rows and columns are interchanged.
2. If two rows (or columns) of a determinant are interchanged, the sign of the determinant is changed, but its absolute value remains unchanged.
3. If all the elements of a row (or column) of a determinant are zero, the value of the determinant is zero.
4. If two rows (or columns) of a determinant are identical, its value is zero.
5. If all the elements of a row (or column) of a determinant are multiplied by the same number, the determinant is multiplied by this number.
6. If each element of a row (or column) is expressed as the sum of two or more numbers, the determinant can be expressed as the sum of two or more determinants; thus, for a determinant of the third order:

$$\begin{vmatrix} a_1 + a'_1 & a_2 & a_3 \\ b_1 + b'_1 & b_2 & b_3 \\ c_1 + c'_1 & c_2 & c_3 \end{vmatrix} = \begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix} + \begin{vmatrix} a'_1 & a_2 & a_3 \\ b'_1 & b_2 & b_3 \\ c'_1 & c_2 & c_3 \end{vmatrix}.$$

7. The value of a determinant is not changed if to each element of any row (or column) there be added the corresponding elements of any other row (or column) each multiplied by the same number.

If in any determinant we strike out both the row and column in which any particular element lies, and then form the determinant of the remaining elements without changing their relative positions, the new determinant so formed is called the minor of that element.

The evaluation of determinants is generally based on an expansion of the determinant in terms of minors by use of the following rule: a determinant may be expressed as the sum of the products of each of the elements of any one of its rows (or columns) by their corresponding minors, each product having a positive or negative sign according as the sum of the row-number and column-number for the particular element considered is even or odd.

If H_k is the minor of an element h_k of a determinant, where the element lies in the h^{th} column and k^{th} row, then $\overline{H}_k = (-1)^{h+k}H_k$ is called the co-factor of h_k.

The expansion of the determinant may then be written in any of the forms:

$$\begin{aligned} D &= a_1\overline{A}_1 + a_2\overline{A}_2 + a_3\overline{A}_3 + \cdots + a_n\overline{A}_n \\ &= b_1\overline{B}_1 + b_2\overline{B}_2 + b_3\overline{B}_3 + \cdots + b_n\overline{B}_n \\ &\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots \\ &= l_1\overline{L}_1 + l_2\overline{L}_2 + l_3\overline{L}_3 + \cdots + l_n\overline{L}_n \end{aligned}$$

Any sum, such as $b_1\overline{A}_1 + b_2\overline{A}_2 + \cdots + b_n\overline{A}_n$, obtained by adding the products of the elements of any row (or column) with the co-factors of the corresponding elements of any other row (or column), is zero.

The evaluation of determinants is based on the use of the preceding properties of determinants, particularly 7, and the expansion by minors, reducing the given determinant in order successively by one until its order is 3 or 2, when it can be directly evaluated by the definition of the second or third order determinant.

The product D' of two determinants D_1 and D_2 of the same order is obtained thus: multiply the elements of the i^{th} row of D_1 by the corresponding elements of the k^{th} column of D_2; the sum of the products thus obtained is the element in the i^{th} row and k^{th} column of the product determinant D'.

One of the chief uses of determinants is in the solution and study of the properties of **systems of linear equations.** (L.L.S.)

DETERMINATE STRUCTURE. Any structure in which the reactions and stresses can be found by means of the equations of **statics** only is a determinant structure. If a sufficient number of such equations cannot be set up from known conditions, the structure is not statically determinate. (C.W.C.)

DETONATION. The term detonation in ordinary usage denotes any explosion. In the **explosives** industry, however, a detonator is an explosive or device used to initiate the explosion of another explosive, which can thus be less sensitive, and more safely handled and transported. Also, detonation is the term describing the knock or ping which, under certain circumstances, occurs in the cylinders of an internal combustion engine. Detonation is undesirable. It reduces power output, causes overheating, unduly stresses the cylinder head, and is generally objectionable from the noise and vibration standpoint. It decreases **thermal efficiency.**

In spark ignition engines, detonation appears to be due to spontaneous ignition of the explosive gasoline-air mixture in the cylinder head. Observers have noted that with no detonation, ignition of the charge starts at the spark plug and travels rapidly, but with a definite wave front, through the charge. However, when the engine is knocking, the inflammation proceeds normally only part way from the source of ignition, and then suddenly the remainder of the charge is ignited simultaneously at all points, accompanied by a sharp rise in pressure due to almost instantaneous expansion. The result is a heavy pressure wave striking the cylinder head hammer-like blows causing it to vibrate audibly. The explanation advanced for this sudden ignition of the entire charge is that the initial combustion increases the pressure of the rest of the charge, and its temperature, until it passes the point where ignition will take place spontaneously due to **adiabatic** compression.

Conditions affecting detonation might be discussed under three heads: viz., fuel characteristics, cycle characteristics, and engine characteristics. The rate at which a fuel burns when ignited is the first of the fuel characteristics. Since the ratio of air to fuel in the combustible mixture also affects the rate of burning, it has a bearing on detonation. The spontaneous ignition temperature of the fuel is another important characteristic. Turning next to the **cycle** upon which the **engine** is operating, we find the compression ratio and the time of ignition to be of great importance. The overcoming of detonation is of increasing importance, as compression ratios of engines are raised in the effort to increase thermal efficiency. The driver of an automobile with manually controlled ignition knows detonation may be offset by retarding the spark. But this is undesirable, since it is accompanied by loss of power and overheating. One of the more important engine characteristics affecting detonation is the material of the combustion chamber. The more rapidly heat is conveyed away from the cylinder head, the less will be the chance of the initial combustion raising the pressure above that for spontaneous ignition. Thus aluminum cylinder heads and improved cooling efficiency offset detonation in high compression engines. Manufacturers' provisions for thus conducting heat away rapidly will be nullified by a heavy layer of heat-insulating carbon deposit in the cylinder head. Other engine characteristics of importance are the location of the spark plug and the shape of the combustion chamber.

It is known that certain substances have the ability to suppress this kind of detonation. How they act is not fully known. Amounts of suppresser as small as one molecule to 100,000 molecules of explosive mixture are effective in eliminating detonation. The detonating quality of a gasoline is one of its comparable characteristics. A scale called octane rating has been devised to measure this quality. The octane rating is the percent by volume of isooctane in a heptane-isooctane mixture (see **Hydrocarbon**), which exactly matches in antidetonating property, an actual fuel under test in a standard test engine at standard conditions.

Lead tetraethyl in small quantities is effective as a knock suppresser. To prevent a lead deposit from forming in the cylinder head, ethylene dibromide is added to form a lead bromide which is powdery and is blown out through the exhaust ports. Gasoline so treated is called ethyl gasoline.

The compression ignition engine also experiences a knock from the combustion of improperly selected fuels. It is believed that combustion knock in a **Diesel engine** is caused by delay in **ignition** during the first part of fuel injection, causing accumulation of fuel which burns simultaneously with the fuel injected during the latter part of the injection. Detonation in these engines is aggravated by the slow-burning characteristic that is anti-knocking in spark ignition engines. Good ignition quality, as represented by high **Cetane Number,** minimizes the delay period and the tendency of a compression ignition engine to knock. (F.T.M.)

DETRITUS. General term for unconsolidated **sediments** derived from pre-existing rocks by natural agencies. Derived from the Latin word meaning worn. (R.M.F.)

DEUTERIC. Used by **petrologists** to describe those alterations in an **igneous rock** which occur during the later stages of its solidification. (R.M.F.)

DEUTERIUM. Symbol: D. Atomic number: 1. Atomic weight: 2, the second isotope of hydrogen, 0.02% of ordinary hydrogen. Discovery by Urey in 1932.

Oxide: Deuterium oxide (D_2O), heavy water.

(See **Hydrogen; Water.**) (R.K.S.)

DEUTEROCEREBRUM. The second region of the **brain** of an **arthropod,** derived from a pair of ganglia (see **Ganglion**) in the corresponding segment of the head. (A.W.L.)

DEUTERON. Nuclear Particles.

DEUTOPLASM. Inert material stored in **eggs. Yolk.** (A.W.L.)

DEVELOPERS. Developing Agents; Photography.

DEVELOPING AGENTS. Developing agents are selective inorganic or organic reducers which have the

ability to distinguish between exposed and unexposed silver halide grains in an emulsion and have only sufficient energy to reduce exposed silver halide grains to metallic silver, thereby converting the latent image into a visible one.

Certain chemical reducers are too energetic; they reduce all the silver halide particles in an emulsion, causing complete fog. These are unsuited for photographic use. The energy of any developing agent is subject to the variations in emulsions, in exposure, and in the composition of the developing solution in which it is incorporated. The developing agent that is satisfactory in one case may not be suitable in another.

Developing agents can be broadly divided into two general classes: (1) those in which a metal undergoes a change in valence, and (2) those which do not contain a metal or in which the valence of the metal does not change. Inorganic compounds and metallic salts of organic acids belong to the first class, while the organic developing agents and certain inorganic compounds, as peroxide, hydroxylamine and sodium-hydrosulfite, are members of the second.

Inorganic Developing Agents. Among the small number of inorganic substances that have been found to act as photographic developing agents are ferrous fluoride, ferrous oxalate, ferrous citrate, copper chloride, cuprous bromide, cuprous iodide, sodium hydrosulfite, hydrogen peroxide, hydroxylamine, and hydrazine. Most of these compounds are of academic interest only. Many of the agents listed produce by-products or gases which are harmful to emulsions. Ferrous oxalate, however, was used for many years in negative developers. Sodium hydrosulfite, although unstable, is about the only inorganic developer that is used today. Inorganic developing agents have given way to organic compounds because the latter have more desirable properties, keep longer in solution, and are easier to control.

Organic Developing Agents. Several hundred organic compounds have been described in photographic literature as possessing developing power. Of these, only about a dozen are of practical use in black and white photography. The number used for processing color materials probably does not exceed twice the number of black and white agents. In some instances the same agent can be employed for both black and white and color photography. The remaining agents are, therefore, of scientific and research interest.

Organic developing agents can be considered to be organic derivatives of hydrogen peroxide HO—OH, hydroxylamine H_2N—OH and hydrazine H_2N—NH_2. For consideration, these may be divided into three groups:

1. Derivatives in which one or both of the hydrogens of an amine group, —NH_2, are substituted.
2. Derivatives in which organic radicals are inserted between the hydroxy and amino groups.
3. Some aliphatic compounds containing the characteristic hydroxy or amino groups also act as developing agents.

Common Developing Agents. Because of the flexibility of developing agents, it is possible to obtain a great variety of results with a small number of compounds.

By far the greater number of developing solutions today make use of only two agents, metol and hydroquinone. In some instances a third agent, such as glycin, chlorhydroquinone or pyrogallol, is added. Some solutions, notably process developers, make use of only one agent—hydroquinone. By varying the type of alkali and amount of restrainer almost any control may be obtained.

Amidol (Acrol, Diamol). Chemically the agent is known as 2-4 diaminophenol. Amidol is capable of development without an alkali. With sulfite it forms a soft working developer adapted to the development of bromide papers. It deteriorates rapidly in solution becoming inactive in a day or two. The keeping qualities of the solution may be improved by additions of boric, glycollic or lactic acids. Best results are obtained by mixing the developer immediately before use. Combined with sulfite, metabisulfite and bromide, it has been a popular developer for lantern slides and opal plates. The agent is usually sold in the form of the dihydrochloride, 2-4 $(NH_2)\cdot C_6H_3OH\cdot 2HCl$, for stability.

Catechol (Pyrocatechin). Catechol, also known as ortho hydroquinone, is a 1-2 dihydoxy benzene, 1-2 $(OH)_2\cdot C_6H_4$. It is often substituted for hydroquinone in formulae. It is specified in developers which harden emulsions during development and has been used in the pinatype process for making imbibition prints.

Chlor Hydroquinone (Adurol, Chlorquinol), 3-Cl, 1-4 $(OH)_2\cdot C_6H_3$. In behavior chlor hydroquinone is similar to hydroquinone but is more energetic especially at low temperatures. It is less sensitive to the action of restrainers and does not show as great a tendency to fog or stain as hydroquinone. It is combined with metol for negative development. It is also a component in some fine-grain developers. In combination with hydroquinone in carbonate developers it produces warm tones on chloride and chlor bromide papers.

Glycin (Athenon, Monazol, Iconyl). Glycin, or para-hydroxyphenylamino-acetic-acid, has the formula $HO\cdot C_6H_4\cdot NH\cdot CH_2COOH$. The agent is insoluble in water but dissolves readily in sodium sulfite solutions. It is a slow acting but powerful developing agent, producing fine-grained silver images with a marked freedom from fog even in the absence of alkaline bromides. Glycin, unlike most developing agents, is not oxidized by air, nor does it produce a stain image. It keeps well in solution and is recommended for deep-tank developing. Glycin is usually used in combination with metol, with para-phenylene diamine for fine grain developing, or with hydroquinone for warm tones ranging from warm blacks to browns, depending on dilution. In combination with metol and hydroquinone it produces the rich jet blacks particularly desired in salon prints.

Hydroquinone (Quinol). Hydroquinone, 1-4 $(OH_2$ C_6H_4 1-4 dihydroxybenzene, is the second oldest developing agent discovered by Abney in 1881. Hydroquinone is used to a greater extent than any other agent. It has a low energy, is very sensitive to restrainers, and is practically inactive at temperatures below 59° F. Because hydroquinone produces density rather than detail in images, it is used as an agent for producing contrast. Unless the developers containing hydroquinone have sufficient sulfite and bromide, the images are heavily stained and fogged.

Hydroquinone, in strong alkaline solutions as carbonate or hydroxide, is an excellent developer for line copy work. Combined with paraformaldehyde it produces the extremely high densities and contrasts desired in graphic arts.

For general photographic purposes it is combined with metol to produce a great variety of results, ranging from fine grain to process negatives and as standard developer for prints.

In developers having low concentrations of sulfite, the oxidation products of hydroquinone harden the gelatin in contact with the silver image. Reliefs made in this manner can be dyed and used to transfer dye images in color photography.

Metol. (Common trade names are Elon, Veritol, Genol, Pictol, Photol, Rhodol, Errol, Scalol, Satrapol, and Mirol.) N-Monomethyl-para-amino-phenol-sulfate, $HO\cdot C_6H_4\cdot NH\cdot CH_3\cdot \frac{1}{2}H_2SO_4$, or metol, since its introduction by Hauff in 1891, has been one of the most popular developing agents. Practically every photographic manufacturer and photo supply-house packages the developing agent under their own trade name.

Metol is a rapid, soft working developer that develops detail. It is not very sensitive to bromide or restrainers. It has good keeping qualities and a long useful life. Used alone, it will develop a larger quantity of sensitive material than any other agent without becoming ex-

hausted. Although metol will develop images without an alkali it is usually incorporated in solutions containing carbonates, borax or borates. It is usually necessary to add some bromide to metol developers to prevent fog.

Since metol produces detail and hydroquinone builds contrast, the two agents can be combined in various proportions with different alkalies to produce almost any result desired, a fact which explains the wide popularity of the M-Q developers.

Other combinations as metol-pyro, metol-glycin and metol-hydroquinone-glycin are also popular.

Developers containing only metol and sulfite or metol, sulfite and bisulfite produce fine-grained images with excellent shadow detail and contrast.

Para-aminophenol. The free base $HO \cdot C_6H_4 \cdot NH_2$ is only slightly soluble in water; hence salts such as the hydrochloride, sulfate, oxalate or tartrate are employed. The compound is the parent substance from which all of the paraaminophenol developing agents are derived.

In solution with alkaline carbonates, paraaminophenol is a rapid, soft working developer. It produces images which are remarkably free from fog, even at temperatures above normal. For this reason it is recommended for both tropical and high-temperature development. Paraaminophenol developers can be prepared in highly concentrated solutions which have exceptional keeping properties.

Paraphenylenediamine (Diamine, Dianol, Paramine, P.P.D.). The free base $H_2N \cdot C_6H_4 \cdot NH_2$ is very slightly soluble in water. It is alkaline and may be used without an alkali. The hydrochloride $C_6H_4(NH_2)_2 \cdot 2HCl$ is more soluble in cold water than in hot. The salt is acid and must be made alkaline before it will develop. Both the base and the salt keep in the dry state if they are protected from air.

Both forms of the developer are toxic and produce painful skin eruptions on persons who are sensitive or allergic. Persons affected should wear rubber gloves when working with either the developer or its solutions.

The fine-grain properties of paraphenylenediamine developers were observed by Lumiere and Seyewetz in 1904. Fine-grain development is due to the low reduction potential of paraphenylenediamine and to its solvent action on silver halides; a condition that produces low effective emulsion speeds and necessitates increased exposures.

Silver images resulting from paraphenylenediamine developers are dichroic; they appear black by transmitted light and cream colored by reflected light. In reflected light the negatives often appear as positives. Because paraphenylenediamine produces stained images, negatives which appear quite thin produce prints with good quality and contrast.

To overcome the need for prolonged exposures, other developing agents having higher reduction potentials, as metol, glycin, hydroquinone, chlor hydroquinone and pyrogallol, are combined with paraphenylenediamine.

Paraphenylenediamine has also been used to produce warm-tone fine-grain images on lantern slides and motion-picture film.

Paraformaldehyde, a polymerized form of formaldehyde, is a solid. This agent, combined with hydroquinone in strongly alkaline developers, produces process or line developers with extreme contrast for graphic arts.

The energy of the solutions increases, after mixing, to a maximum in 4 or 5 days and then gradually decreases over a period of several weeks. It is necessary, therefore, to adjust the time of development according to the age of the developer.

Pyrogallol (Pyro, Piral). Pyrogallol, 1-2-3 $(OH)_3 C_6H_3$, is the oldest known organic developing agent. It was discovered independently by both V. Regnault and S. Archer in 1851.

Pyrogallol, in pure form, is a small, fine, white crystalline needle-like powder which is extremely light and floats through the air with the slightest movement. Pyrogallol is also obtained in heavy white flake crystals which are easier to handle and dissolve more rapidly during mixing. The crystal form is more stable and does not oxidize as rapidly as the powder.

Pyrogallol is a slow, soft working developing agent which forms both a stain and a silver image. The combination of the yellow stain and silver produces brown images that print more contrasty than they appear visually. While the stain formation may be inhibited by additions of sulfite and other preservatives, the developer is subject to oxidation by exposure to air and by oxidation at increased temperature and agitation.

The objections to using pyrogallol are the difficulties in controlling the stain formation and in obtaining negatives with a uniform stain deposit. The keeping qualities of the pyrogallol developers are poor. It is generally advisable to use a fresh bath with each batch of film. In order to obtain greater contrast and shorter times of development, pyrogallol is combined with metol, hydroquinone and an alkaline carbonate as an alkali. Metol-pyrogallol developers are popular for portraiture. Combinations of pyrogallol and paraphenylenediamine are used in fine-grain developers. (S.M.T.)

DEVELOPMENT. **Developing Agents; Photography; Sheet Metal Processes; Press Working.**

DEVIATION. The deviation of x from a is defined as $x - a$. If a is the **mean** we define $d = x - \bar{X}$. If a is any other point we define $d' = x - a$. If a is the **median** we have a deviation from the median. The absolute value of the deviation of x from a is defined as $|x - a|$. (See **Compass Correction.**) (L.A.A.)

DEVIATION RATIO. **Modulation.**

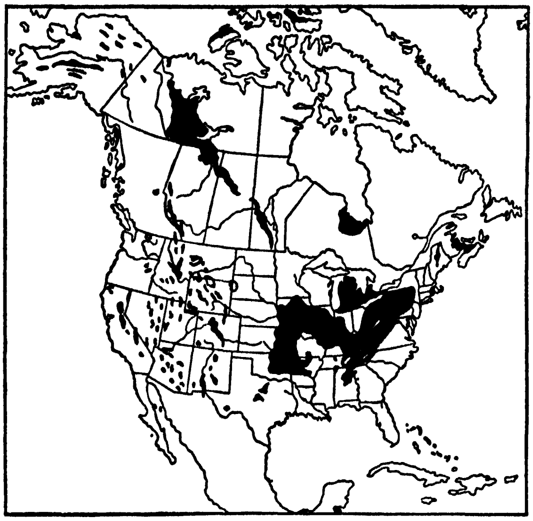
DEVIL FISH. 1. Mollusca, Cephalopoda. Any **octopus.** 2. Pisces, Plagiostomi. The giant **ray.**

Both of these forms are said to be dangerous to man, and when we consider that they are predacious and that some reach large size we can readily believe that they may attack divers. One octopus of the Pacific Ocean reaches a diameter of more than 20′ and the ray attains an equal width. (A.W.L.)

DEVITRIFICATION. The process by which the natural rock glasses, such as **obsidian** and **tachylyte,** develop minute but definite minerals, usually **quartz** and **feldspar.** (R.M.F.)

DEVONIAN. The name of a geologic period. Type locality, Devonshire, England. The formations of this period were first studied and described by R. I. Murchison in 1839. The Devonian period began 330 million years ago and lasted for 50 million years. The Devonian formations are well exposed in eastern North America and parts of the North American Cordilleran. In the **Appalachian Geosyncline** the Devonian is largely represented by an immense thickness of red and brown shales and sandstones of deltaic and estuarine origin, and the transition between the sediments of this system and that of the underlying Silurian is so gradual that the boundary is extremely difficult to locate by physical means alone. In Britain the Devonian is represented by a marine limestone (facies) in the type locality, and a red non-marine sandstone (facies) to the north. This red sandstone (facies) is referred to as the "Old **Red**" by British geologists. The Scottish "Old Red" contains the famous fossil "fishes" described by Hugh Miller in 1851. These fish include two distinct groups, **Ostracoderms** and **Ganoids,** the latter being the supposed ancestors of the Amphibia or first terrestrial vertebrates.

The first undoubted evidence of terrestrial plants occurs in the Devonian, the late Devonian types being the progenitors of the **Carboniferous** forms. In England,



Map showing known areas of outcrops (surface distribution) of Devonian, Mississippian, and Pennsylvanian strata in North America.

Scotland, Spitzbergen, western Russia, and Norway, occur great thicknesses of terrestrial, intermontane clastic sediments similar to those found in the **Proterozoic.** Highly fossiliferous marine sediments, including sandstones, shales and limestones are particularly well exposed in New York State. Many of the limestone formations contain reefs composed principally of compound corals, **Bryozoa** and **Calcareous Algae.** Among the marine invertebrates **goniatites** and **Eurypterids** are particularly representative. Other common marine types are corals, **Bryozoans** (reefs) and **Echinoderms, Pelecypods** and **Trilobites.** The spire-bearing Brachiopods (**Spirifers**), which started in the Silurian, reach their maximum development in genera and species in the Devonian. The only fossil evidence of a terrestrial vertebrate rests upon a footprint (probably that of an amphibian) found in the Upper Devonian of western Pennsylvania. Beginning with the middle and ending with the period, mountain building occurred in the New England States. The principal economic products derived from the American formations are petroleum and natural gas, first exploited in 1859 in western Pennsylvania, New York, Ohio and West Virginia. (R.M.F.)

DEVONITE. The name given by Johannsen, in 1910, for a variety of **porphyritic basalt** containing **phenocrysts** of **potassium-rich plagioclase.** Type locality, Mt. Devon, Massachusetts. (R.M.F.)

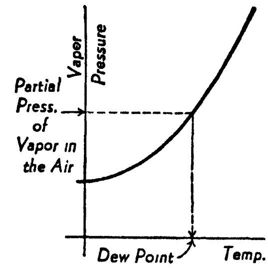
DEW. If air in contact with any surface is cooled at the surface to a temperature below its dew point, some of the water vapor present in the air will condense onto the cool surface as liquid water or dew. When temperatures are below freezing, hoarfrost forms instead. (P.E.K.)

DEW CLAW. Small hoofs of the rudimentary toes, found just above the functional hoofs in some of the even-toed hoofed animals. (A.W.L.)

DEWLAP. The fold of skin which hangs below the neck in cattle. (A.W.L.)

DEW-POINT HYGROMETER. Hygrometers; Dew Point.

DEW-POINT TEMPERATURE. The temperature to which air must be cooled to become saturated is its dew-point temperature, but the cooling must be carried out at constant pressure. It is the temperature at which the



Graphical location of dew point from vapor pressure curve.

maximum vapor pressure of water would be equal to the actual partial pressure of the water vapor in the atmosphere (see **Dalton's law**). For example, let the temperature of the air be 20° C., and the relative humidity 60%. Then since the maximum vapor pressure of water at 20° C. is 17.4 mm., the actual water vapor pressure is 0.6 of this or 10.4 mm. The temperature at which 10.4 mm. is the maximum vapor pressure of water is 12°. Hence if the air is cooled to 12° C., it will reach saturation and under suitable conditions dew will form; 12° C. is the dew point. Likewise if the dew point is known to be 12° when the air is at 20°, it follows that the relative humidity is 60%. The dew point **hygrometer** depends upon this principle. (L.W.D., P.E.K.)

DEXTRIN. Carbohydrates.

DIABASE. Dolerite.

DIABETES MELLITUS. A disease of **metabolism** in which those processes concerned with the formation and utilization of **carbohydrates** are disturbed. An outstanding feature is the deficient supply of **insulin,** a **hormone** produced by the **pancreas.** Insulin is necessary for the utilization of carbohydrates, and when it is decreased in amount in the body, the metabolism of carbohydrates, and secondarily proteins and fats, is upset. As a result, large amounts of unused sugar appear in the blood and overflow into the urine. Intermediary products in the metabolism of fats and proteins, ketone or acetone bodies, also appear in the blood and urine, and their presence in large amounts is associated with diabetic **coma** and **acidosis.**

It is estimated that there are 660,000 diabetics in the United States and the incidence of the disease is increasing steadily. This is due in part to its hereditary nature and to improved treatment. Diabetic children now live to adult life, marry, and may produce diabetic children.

The cause of diabetes is obscure but many factors are known to play a part. The most important are (1) heredity, (2) endocrine gland disturbances—chiefly involving the **pituitary,** the **adrenal** cortex, and the **thyroid,** (3) obesity, (4) a varied group of factors such as age, sex, race, infection, etc.

1. The inheritance of diabetes as a Mendelian recessive (see **Heredity**) is well established. If both parents are diabetic, all of their children will have diabetes. If one parent has diabetes and the other neither has it nor carries a gene for it, none of their children will have the disease. Diabetes could, therefore, be bred out of the species over a number of generations by the consistent union of diabetics with individuals from nondiabetic families.

2. The interaction of the endocrine glands in the control of metabolism is complex and not fully understood. It has been shown that a derangement of the normal relationships of the glands may result in diabetes. The

pituitary under certain circumstances can manufacture a diabetogenic (diabetes-producing) factor. The adrenal cortex is important in carbohydrate metabolism but its exact action is not known.

3. Obesity is associated with diabetes in several ways. Although the popular conception that increased sugar consumption and obesity can directly cause diabetes is incorrect, it is true that diet influences the appearance of the disease in a susceptible individual. This is borne out by the fact that mild diabetes can be controlled by diet; and if a patient requires insulin, increasing the diet increases the amount of insulin necessary. If an individual has a low pancreatic reserve, the strain on the insulin-producing tissue which would exist over a long period under the dietary circumstances leading to obesity, might be expected to result in a situation where the insulin supply is inadequate.

4. The time of life at which diabetes is most likely to occur is in the 4th and 5th decades, and the disease is far more common in women than in men. The Teutonic races are more susceptible than the Latin. The incidence in the Jewish race is greater than in any other; this is due in part to inbreeding, heredity, and the tendency to obesity in middle life. Occupation can be correlated with diabetes in that the incidence is much greater in the professional groups, those of sedentary employment, and in the higher income groups.

The symptoms of diabetes are weakness, weight loss, excessive appetite and thirst, and the excretion of excessive amounts of urine. Treatment with insulin, which was isolated by Banting and Best in 1921, is life-saving in severe diabetics. In mild cases, dietary control alone may be sufficient. With the use of diet and insulin diabetics can now lead a normal, productive life. (D.M.H.)

DIAGENESIS. A term proposed by Gumbel in 1888 for the gradual and successive chemical physical changes which take place in **sediments** previous to or during their **consolidation.** Diagenesis may also include the numerous processes of **lithification** but is a useful term only when particularly applied to the more or less contemporaneous chemical alteration of sediments. (R.M.F.)

DIAGONAL. Any inclined **web member** of a **truss** other than the **end post** is known as a diagonal. Under various **live load** conditions certain web members of a **bridge** truss may be subjected to a **reversal of stress.** Stiff diagonals are web members designed to carry either **tension** or **compression.** Tension diagonals are assumed to be incapable of resisting any appreciable amount of compression.

When the diagonals are designed to take tension only (are not stiff) two are required, sloping in opposite directions, in a panel where either one, acting alone, would have its stress reversed. When one of these diagonals is acting the other is out of action for all practical purposes. The one which carries the **dead load** stress when no other loads are on the bridge is called the main diagonal. The other which comes into play when the main diagonal goes out of action is the counter. (C.W.C.)

DIAGRAM FACTOR. This is a factor relating particularly to **piston** and **cylinder** engines. Although it has a meaning applied to internal combustion engines, diagram factor is principally a dimension of the **steam engine.** Certain analyses of the steam engine, especially those concerned with predicting the performance of a given unit under stated steam conditions, are most easily made with the use of the diagram factor. This factor is defined as the ratio of the actual **mean effective pressure** to the theoretical effective pressure; also as the actual work to the theoretical work. The theoretical case is that of a steam engine having no compression, no wire drawing, and no clearance. (See **Rankine Cycle.**) The ratio of the area of this cycle to that of the actual engine operating between the same pressure limits, is typical for any one class of engine. The accompanying table gives

DIAGRAM FACTORS

High-speed, simple automatic	0.70–0.85
Low-speed, releasing gear	0.80–0.90
Uniflows	
Full compression, condensing	0.75–0.85
Full compression, non-condensing	0.70–0.80
Controlled compression, condensing	0.85–0.90
Controlled compression, non-condensing	0.80–0.85

some values of diagram factor for steam engines. Knowing the steam conditions, and the type of engine, the probable pressure and horsepower realizable can be closely estimated by calculating the theoretical quantities and multiplying them by the diagram factor. In this light, diagram factor is a means of modifying theoretical calculations to bring them in line with actual experience.

$$P_a = P_t \times f$$

$$IHP = \frac{2P_aLAN}{33{,}000}$$

P_a = actual mean effective pressure, in pounds per square inch.
P_t = theoretical mean effective pressure, in pounds per square inch.
f = diagram factor.
IHP = indicated horsepower (steam engine).
L = stroke in feet.
A = piston area, in square inches.
N = rotative speed, in revolutions per minute.

(F.T.M.)

DIALLAGE. The mineral term for a **calcium-iron pyroxene,** similar in chemical composition to **diopside** but richer in iron oxide. In addition to the typical prismatic cleavage of the pyroxene group diallage has a marked "cleavage" parallel to the vertical **pinacoids,** known as diallage parting. Diallage is a common constituent of **gabbros.** The term Diallagite was proposed by Cloiseaux in 1845 for rocks particularly rich in diallage. The term diallage is derived from the Greek meaning difference, and referring to the peculiar cleavages of this variety of **monoclinic** pyroxene. (R.M.F.)

DIALYSIS. This is a process of removing crystalloids from **colloids** by means of semi-permeable membranes. (R.K.S.)

DIAMAGNETISM. **Magnetism.**

DIAMETERS OF CONICS. The **locus** of the midpoints of all chords parallel to a given chord of a **conic section** is called a diameter of the conic; it is a straight line in each case.

The diameter of the **parabola** $y^2 = 2px$ which bisects all chords of **slope** m is the line $y = p/m$ which is parallel to the axis of the parabola.

The diameter of the **ellipse** $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ which bisects all chords of slope m passes through the center and has the slope $m' = -b^2/a^2m^2$. The diameter of the **hyperbola** $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$ which bisects all chords of slope m passes through the center and has the slope $m' = b^2/a^2m^2$.

Two diameters of an ellipse or hyperbola are called conjugate diameters if each bisects the chords of the given curve that are parallel to the other. For the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, the slopes of two conjugate diameters are related by $mm' = -b^2/a^2$; for the hyperbola $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$,

the relation between the slopes of conjugate diameters is $mm' = b^2/a^2$. (L.L.S.)

DIAMETRAL PITCH. Spur Gearing; Worm Gearing.

DIAMOND. In any enumeration of gem stones the diamond unquestionably stands in first place because of its remarkable brilliancy and great hardness as well as because of its relative rarity. It is an allotropic form of **carbon.** Its luster is also "hard" in quality from which we have derived the term adamantine luster, through the Greek meaning, adamant, applied to diamonds and possibly other very hard substances, literally "unconquerable." In this connection it is interesting to note that the ancients confused hardness with strength or toughness, not understanding that minerals of considerable hardness may split or cleave easily in certain directions. This unfortunate fallacy is believed to have been responsible for the unwitting destruction of more than one diamond.

When colorless, water-clear, and flawless, diamonds are referred to as of the "first water" and are of the greatest value. "Off-color" stones, those with a slight tinge of yellow, are far less desirable although stones of a bright yellow, or of odd colors such as pink or steely blue, command large premiums, as they are highly prized.

The diamond fields of India, now seemingly exhausted, yielded quantities of stones, probably all of those known previous to 1725 when diamonds were discovered in Brazil. That country has produced many fine but mostly small stones.

Diamonds were discovered in 1867 along the Orange River in South Africa, and since then Africa has been preëminent in the production of diamonds; in the seventies and eighties occurred a series of amazing discoveries of diamond fields and stones of extraordinary size. Diamonds have also been found in Australia, Borneo, British Guiana, and Arkansas.

Much as the matter has been studied there is no general agreement as to the genesis of the diamond. It is found in **alluvial** deposits, both unconsolidated and consolidated, indicating the erosion of rocks containing diamonds not only during the present era but also in past geologic time. In Africa diamonds are mined in a dark basic rock of the general nature of **peridotite** called **kimberlite** from the town of Kimberley. The kimberlite occurs in vertical "pipes," resembling what once may have been volcanic necks or other types of igneous rock conduits. It is supposed that the diamonds have been formed in and brought to the surface by the magma which was of the general nature of peridotite. Undoubtedly high pressures, and possibly high temperatures as well, are necessary for the development of crystallized carbon in the form of diamonds. (E.S.C.S.)

DIAMOND DIE. Die; Wire Drawing.

DIAPHRAGM. 1. The thin layers of muscle which suspend the insect heart within the body. 2. The muscular partition between the thoracic and abdominal cavities of mammals.

The mammalian diaphragm is important in **respiration.** (A.W.L.)

DIARRHEA. Increased frequency of bowel movements, the stools tending to be liquid. Diarrhea occurs commonly with infections of the gastro-intestinal tract (e.g., the **dysenteries**) or with any irritation of the bowel. (D.M.H.)

DIASPORE. The mineral diaspore is a hydrous **oxide** of **aluminum** corresponding to the formula $AlO(OH)$ occurring in prismatic **orthorhombic** crystals, usually somewhat flattened, or massive. It displays good cleavage; conchoidal fracture; is brittle; hardness, 6.5–7; specific gravity, 3.3–3.5; luster, vitreous to pearly; color, white, grayish, greenish, yellowish, brownish or colorless; transparent to translucent. Diaspore is found associated with **corundum, emery** and **bauxite,** being probably an alteration product of the oxide. It has been made artificially. Diaspore has been found associated with emery in the Ural Mountains, in Asia Minor, in the Island of Naxos, Greece, and in the United States at Chester, Massachusetts. Its name is derived from the Greek word meaning to scatter, because of its decrepitation upon heating. (E.S.C.S.)

DIASTASE. Enzymes.

DIASTEM. A term proposed for a slight hiatus, or loss of record, during the deposition of sediments. As diastems must be contemporaneous with sedimentation they are not to be confused with **disconformities.** (R.M.F.)

DIASTOLE. The stage of dilation of the heart or relaxation of the **heart** muscle. It is during this stage that the chamber of the heart fills with blood. (R.S.M.)

DIASTROPHISM. A general term for all types and modes of deformation of the crust of the earth. (See **Epeirogeny; Orogeny.**) (R.M.F.)

DIATHERMANCY. Thermal Radiation.

DIATHERMY. The generation of heat in the bodily tissues by means of high-frequency electric currents. Two electrodes are placed on opposite sides of a portion of the body. The heat is generated by the resistance provided by the body tissues between these electrodes.

Medical diathermy is used in **neuritis,** sprains, **arthritis,** etc. Surgical diathermy (endothermy) is used operatively. Sufficient heat is produced at the skin surface either to actively cut the tissues with the current or to coagulate and kill tissue cells. By use of this method in certain conditions, warts, malignant growths, etc., there is less bleeding and less danger of spreading malignant cells. This method can, however, only be used in certain conditions. (R.S.M.)

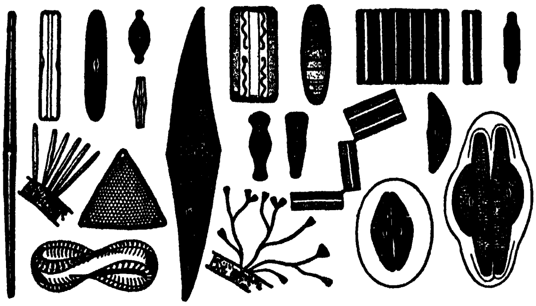
DIATHESIS. Congenital predisposition toward any disease. (R.S.M.)

DIATOM OOZE. Oceanic Deposits.

DIATOMS. Bacillarieae. Diatoms are **algae** which are very commonly found in both fresh and salt waters. Often they occur in immense numbers, especially in the ocean. The feature which distinguishes them from all other algae is the siliceous (see **Silicon**) wall which encloses them. This is composed of two halves or valves, one of which fits over the other much as a cover fits onto a box. These siliceous walls are often beautifully marked with the finest and most regularly arranged patterns which make these algae objects of great beauty when seen under a microscope. Because of the regularity of these marks, certain species are used for testing the resolving power of a **microscope.** Within the wall, the simple **protoplast** contains several **chloroplasts** which may contain a brown pigment that masks the **chlorophyll** present.

Many diatoms are distinctly unicellular organisms; others stick together to form long chains or are included in a gelatinous sheath which forms extensive branching aggregations. There are two large orders of diatoms, separated according to the shape of the cell. One, the Centrales, comprises those diatoms which are radially symmetrical; the other, the Pennales, those which are not radially symmetrical. Many of the Pennales are bilaterally symmetrical, others irregular. Many members of the Pennales move about in a gliding manner.

Two methods of reproduction are found in diatoms. The more common method is asexual. In this process the protoplast of the cell enlarges, pushing the two



Collection of diatoms showing variation in appearance. (*Kerner's Natural History of Plants, Blackie & Son.*)

valves apart. Then the protoplast divides into two parts, each of which occupies one of the two valves. A new valve is formed over the exposed surface of the protoplast but inside the original valve of the cell. As a consequence the new valve is smaller than the original. As repeated divisions occur the size of the valve gradually decreases. This does not continue indefinitely however. To bring the cell back to its original size, auxospores are formed. When this happens the protoplast enlarges tremendously and escapes from its walls. It then divides and secretes about itself new walls which have the size of the original cell. Auxospore formation is often a result of sexual fusions. Sexual reproduction is accomplished by the fusion of two diatoms. There are several variations in the method in which this process occurs. Sometimes it is a simple fusion of two protoplasts to form one; in other forms, two amoeboid gametes are formed by each protoplast. **Gametes** from different protoplasts fuse, forming **zygospores.** Several other variations are known. Some of the Centrales form small bicilate gametes which fuse.

The diatoms are a very important group of algae. Occurring in immense numbers as they often do, they are the main food substance of many animals, which in turn become food for higher organisms, including man. When a diatom dies and its protoplast disintegrates, the siliceous shell sinks to the bottom of the water. Gradually immense accumulations of diatom valves are formed on the ocean bottom. These may eventually be buried beneath other deposits. They become diatomaceous earth, often forming beds hundreds of feet thick and covering large areas. Diatomaceous earth after removal of organic matter is used as an **abrasive** and scouring agent, as a **filter,** and in many other ways. (R.M.W.)

DIATREME. A general term for volcanic pipes and circular vents, the result of the explosive action of **magmatic** gases. (R.M.F.)

DIAZO PROCESS. The use of organic compounds as light-sensitive media for photographic processes is best exemplified by diazo-compounds. The bleaching of these dyes, or dye intermediates, finds its most important application in plan copying papers, as Ozalid, Oce, and Primuline.

The diazo process is based on the fact that exposure causes diazonium salts to undergo photochemical changes which affect their capacity to form dyes. Dyes are formed when diazonium compounds, or diazotized amines, couple with phenols or aromatic amines in a neutral or alkaline medium. During exposure the diazonium compound undergoes decomposition and is thus rendered incapable of coupling and dye formation. Several types of papers are possible. The undecomposed diazo-compound can be developed by immersing the paper in an alkaline solution containing a coupler. The decomposed diazo-compound resulting from exposure couples with the undecomposed compound when the paper is made alkaline. Both the diazo-compound and the coupler are coated together on the paper but are prevented from reacting due to the presence of an organic acid. Papers of this type are dry developed by contact with ammonia fumes.

In the Ozalid process based on the patents of Kogel in 1924, use is made of diazo-anhydrides in a neutral medium because these do not couple until they are alkaline.

The coated paper, which can be handled in subdued daylight, is placed beneath a paper tracing and exposed to light. The exposed portions become bleached while the unexposed portions retain their yellow color. After exposure, the paper is passed over a tank of ammonia vapors which convert the unexposed portions to a dye image. Papers which produce various colored images as black, blue, brown, maroon, purple and green are available. Recently, papers capable of rendering a continuous scale of tones have been perfected. Large-size colored images printed from photographic positives are used for posters and advertising. Foils or film coated with diazo-solutions have high resolution and are finding numerous applications in the fields of microfilming, sound recording and in inter-office, plant, and radio communications. (S.M.T.)

DIAZOAMINO-COMPOUNDS. **Azo-, Diazo-, and Related Compounds.**

DIAZO-COMPOUNDS. **Azo-, Diazo-, and Related Compounds.**

DICHOTOMY. A system or method of branching in which the main axis divides into two branches, which may in turn branch in the same manner, as for example the **thallus** of an **alga** or an **hepatic,** or the root or stem of a **club moss.** (R.M.W.)

DICHROITE. **Cordierite.**

DICKCISSEL. Aves, Passeriformes. A small American bird, *Spiza americana,* related to the buntings. It is found in open country and is distinguished by its yellow breast and black throat patch. (A.W.L.)

DICOTYLEDONS. The larger of the two subclasses of **angiosperms** is the dicotyledons, containing over 100,000 species. The plants of this subclass have leaves, flowers and seeds distinctly different from those of **monocotyledons.** The leaves are generally broad and have netted veins; the parts of the flowers occur most frequently in fours or fives or multiples of these numbers. That is, there are 4 or 5 sepals, 4 or 5 petals, 4 or 5 (8 or 10, or more) stamens, and one to many pistils. The embryo of the seed has two cotyledons or seed leaves.

Many important food plants are members of this group; for example, **potato, cabbage, carrot, apples, oranges,** and **peanuts.** Other dicotyledons yielding economic products of great value are the various **rubber** plants, **cotton, flax, sugar** beets, and soy beans. The number cultivated as ornamental plants is too great to enumerate.

Dicotyledons vary in size from tiny annuals an inch or less in height to giant trees 350′ tall. They include herbaceous and woody members, annuals, biennials, and perennials. They are found all over the world, wherever plants can grow. (See also **Paleobotany.**) (R.M.W.)

DICTYOKINESIS. A process of subdivision of the Golgi apparatus of the cell during cell division, followed by the distribution of the resulting parts to the daughter cells. (A.W.L.)

DICTYOSOME. Cell.

DICTYOSTELE. Stele.

DIDELPHIA. Mammalia.

DIE. There are several commonly accepted usages of this term. In thread-cutting, a die is a tool resembling a slotted nut, and is used for cutting external threads on screws, bolts, and pipe. In wire drawing, a die is a device used to procure plastic flow of metal; the die is usually, although not necessarily, made with a bell-mouthed circular hole, into which the end of the wire is introduced. In the past, hardened steel dies for wire drawing were extensively used; at the present time, either tungsten-carbide or diamond dies are used, since the wear and abrasion on the die are considerably reduced. (See also **Die Casting, Drop Forging, Plastic Molding, Press Working.**) (H.C.H.)

DIE CASTING. Die castings are produced by forcing molten metal under pressure into a steel die. The pressure is maintained until solidification is complete. The process is essentially a further development of gravity-feed casting, but the pressure function entails finer detail and better finish. While gravity-feed casting tonnage is greater than that of pressure casting, the latter has a wider field of application and is more important in the quantity production of precision parts. Zinc alloys are generally used for die castings, although aluminum alloys, brass alloys and other non-ferrous metals are used to a considerable extent.

The process of die casting is entirely automatic and requires the following elements: a die-casting machine to hold the molten metal under pressure; a metallic mold or die capable of receiving the molten metal, and designed to permit easy and economical ejection of the solidified product; and a casting alloy that will produce a satisfactory product with suitable physical characteristics.

There are two types of die-casting machines: The first, or air-operated machine, forces the material into the die by high pressure on the surface of the molten metal in a special ladle or goose; and the second, or plunger type machine, forces the material into the die by means of a cylinder and piston which are submerged in the molten metal.

Die-casting dies are constructed in different styles for various production requirements. A single die contains an impression of only one part; a multiple die contains two or more impressions of any one part; a combination die contains one impression only of two or more parts; and a combination-multiple die contains a number of impressions of each of two or more parts. Single dies are comparatively cheap and are used for small-lot production, since they reduce the tool investment to a minimum for any one part. Combination dies, when properly planned, will reduce the total die cost for a given set of castings to a minimum. They are applicable to parts that will always be used in the same quantities and of the same alloy. These parts should be of the same general character and weight. Multiple dies are usually slower to operate than single dies but will give higher production rates for the same labor costs.

Die-casting dies are often vented by permitting air to escape through the clearance in the ejector and core pin bearings. The problem of venting is considerably more important than in sand casting because the mold has no porosity. Sometimes dies are vented by grinding shallow grooves on the parting surfaces of the dies; in other instances plugs with suitable vent grooves are added to the die. (H.C.H.)

DIE SINKING. The process of cutting a recess or cavity in a die for drop forging, press working, or plastic molding. (See also **Hob.**) (H.C.H.)

DIELECTRIC ABSORPTION. The persistence of electric polarization in some **dielectrics** after the removal of the polarizing electric field. When a **condenser** with glass plates is connected with a **battery,** the charging current may last, though gradually decreasing, for some minutes or hours; and when the charged condenser is short-circuited, the discharge current may not cease entirely with the first rush. After a **Leyden jar** has been discharged and allowed to stand disconnected for a time, another, smaller spark can usually be obtained from it. This is called a "residual" charge.

By melting mixtures of wax and allowing them to harden in a strong electric field, Eguchi (Japan, 1925) succeeded in obtaining dielectric absorption which persisted almost undiminished for several years. Such a permanently polarized body, singularly analogous to a permanent magnet, has been termed an "**electret.**" (L.D.W.)

DIELECTRIC CONSTANT. Dielectrics.

DIELECTRICS. A dielectric is a body through which, or a medium in which, electric attraction or repulsion may be sustained. Thus glass is a dielectric, because unlike charges on opposite sides of a plate of glass attract each other; likewise two charged bodies immersed in oil or in nitrogen exhibit mutual electric force (though less than in a vacuum), hence these substances are dielectrics Dielectrics are always insulators; a good conductor completely screens off an electric field (see **Electric Screening**). The **condenser** is the usual form of apparatus for studying and comparing dielectrics

The explanation of most dielectric phenomena is found in what is known as "electric polarization." When a dielectric is placed in an **electric field,** it is believed that there is a slight shifting of the negatively charged particles (electrons), of which it is partly composed, in one direction and of the positive particles in the other, so that the body as a whole now has an electric moment where before it had none; the electric moment per unit volume being the measure of the polarization. This may result partly from a rectilinear shift of electrons and atomic nuclei, and in many cases partly also from the re-orientation of "polar" molecules, i.e., molecules which have a permanent electric moment of their own.

In dielectrics of this latter type, the polarization is greater in the liquid than in the solid state, presumably because the polar molecules turn about more easily. (The whole phenomenon bears a close analogy to the magnetization of iron; an analogy made still more striking by **dielectric absorption,** q.v.)

A notable result of the polarization of a dielectric is the reduction of the electric intensity due to any given distribution of electric charges. It is shown in dielectric theory that if the intensity in a vacuum, called the electric displacement, is denoted by D, that in a dielectric whose polarization is P is $E = D - 4\pi P$. The polarization P is apparently proportional to D. Hence E is proportional to D, and the ratio D/E, which is greater than unity, is called the dielectric constant of the substance, and usually denoted by k. It varies widely for different substances, as will be noted in the brief table below:

DIELECTRIC	k	DIELECTRIC	k
Air	1.0006	Mica	5.7
Alcohol	28.4	Paraffin	2.1
Carbon dioxide	1.001	Porcelain	5.7
Glass (flint)	9.9	Rubber	2.2
Hydrogen	1.0003	Sulfur	4.0
Linseed oil	3.3	Water	81.1

A convenient measure of the dielectric constant is the ratio of the **capacitance** of a condenser filled with

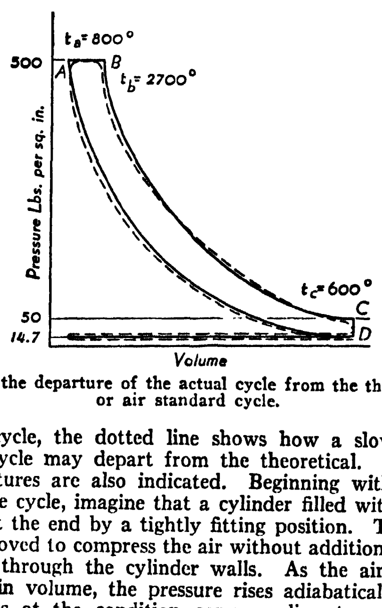
the dielectric in question to that of a similar condenser with the dielectric removed, leaving a vacuum. The electric energy per unit volume in the polarized dielectric, for a given electric field intensity, is also proportional to the dielectric constant; therefore, if the dielectric constants of glass and air are in the ratio 10:1, a condenser with glass plates charged, say, to 1000 volts, has ten times as much stored electrical energy as the same condenser charged to the same voltage but with air substituted for the glass.

With non-polar dielectrics the dielectric constant k depends, for a given substance, upon the density ρ (and hence upon the temperature), increasing as ρ increases in accordance with a formula due to Clausius and Mosotti:

$$k = \frac{2a\rho + 1}{1 - a\rho};$$

in which a is a constant for the given dielectric. For different substances it depends upon a property of the molecule known as its "polarizability," which is the increase of electric moment produced in the molecule by unit electric field intensity. (See also **Electric Insulation.**) (L.D.W.)

DIESEL CYCLE. Although modified from the inventor's original conception, the modern Diesel cycle retains the most important feature, namely that of compression of air to the ignition temperature, followed by timed introduction of fuel. This cycle is shown in the accompanying diagram. The solid line indicates a theo-



Showing the departure of the actual cycle from the theoretical, or air standard cycle.

retical cycle, the dotted line shows how a slow-speed actual cycle may depart from the theoretical. Typical temperatures are also indicated. Beginning with point D on the cycle, imagine that a cylinder filled with air is closed at the end by a tightly fitting position. The piston is moved to compress the air without addition or loss of heat through the cylinder walls. As the air is decreased in volume, the pressure rises adiabatically, and it arrives at the condition corresponding to point A. The piston is then reversed in direction, and starts to move so as to increase the volume of the air. The air is very hot due to its **adiabatic** compression. In fact, it is well above ordinary ignition temperatures of petroleum products. As the piston starts to move, carrying the cycle from point A, fuel is injected or sprayed into the cylinder just rapidly enough so that its combustion will keep the pressure up while the volume is being increased, at least up to point B. At B when the outward stroke is partially completed, the fuel is cut off, and the products of combustion expand adiabatically from B to C, giving work to the piston as they do. At C the exhaust valve opens, and the pressure drops to D. The line extending horizontally from D represents the theoretical exhaust and suction stroke. Adiabatic expansion and compression are not possible in a cylinder which must be well cooled in order to maintain a lubricating oil film. Therefore an actual cycle will not be expected to follow the adiabatic. Another difference between actual and theoretical cases is the composition of the gas within the cylinder. Theoretical studies are made assuming pure air in the cylinder. Actually there is a little burned gas present during the compression, and a great deal of it during the expansion strokes. However, by assuming no friction loss, adiabatic compression and expansion, and air, only, in the cylinder, an expression may be derived for the efficiency of the cycle $ABCD$. (See **Air Standard Efficiency.**) (F.T.M.)

DIESEL ENGINE. In a patent dated 1892, Dr. Rudolf Diesel, a German engineer, described an engine to operate on the **Carnot cycle.** Coal dust was the fuel, and it was to be fed rapidly enough so that isothermal expansion would result. After fuel cut-off, an adiabatic expansion would continue, followed by a compression made isothermal by the injection of water into the cylinder. An adiabatic compression then brought the cycle back to its beginning. A further claim of the patent covered the use of liquid fuels and the spray valve. Early attempts to build this engine resulted in the adoption of a modified cycle which, after much experimentation, was built into a successful working engine. Since then the Diesel has slowly but surely established for itself a secure position as a prime mover.

The reasons for continued growth of Diesel engine power are to be found in the advantages of the Diesel over other prime movers for certain classes of service which abound in this country, and to the comparative low cost of high-grade petroleum fuel.

The Diesel applications at present may be divided into *mobile* and *stationary.* Marine and locomotive service absorbs a large proportion of the annual output of engine builders. Stationary Diesels are to be found in all kinds of factories, especially small factories. A great many of them are used for pumping oil in pipe lines, and from wells, and for pumping water both for drainage and irrigation. They are also in service in mines for pumping, for compressing air, and for electrical service.

The Diesel is an excellent prime mover for electrical generation in capacities of from 100 to 5000 horsepower. As such, it is widely used by private industry, hotels, utility companies, and municipalities, especially in the water and light plants of the latter.

The advantages of the Diesel engine are:

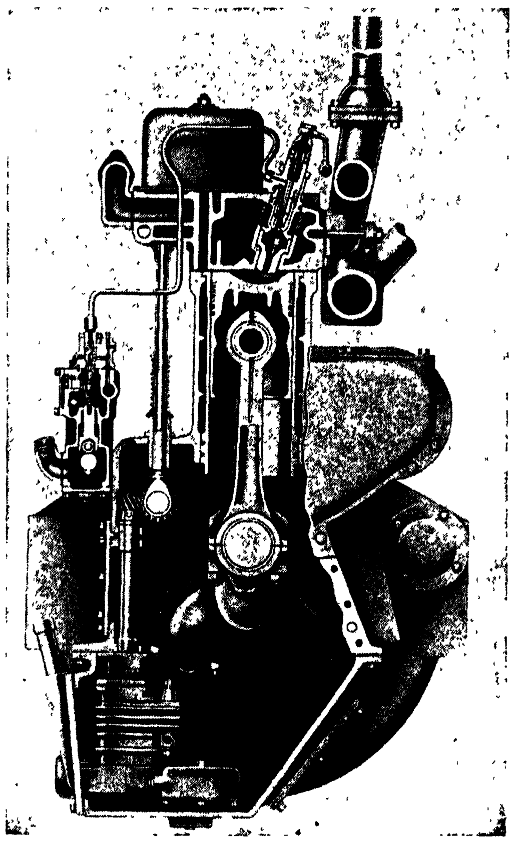
1. Low fuel cost.
2. No long warming-up period.
3. No standby losses.
4. Uniformly high efficiency of all sizes.
5. Simple plant layout.
6. No large water supply needed.

The Diesel can extract more work out of each heat unit than any other engine in the world. For that reason it becomes an attractive prime mover wherever first cost is written off slowly enough so that operating costs are influential.

Where fuel prices favor oil, where prices of all fuels are extraordinarily high, where water supply is either of poor quality or inadequate, where loads are relatively small and reliable transmission line service is not available at competitive rates, and where industrial power rates are too high, the Diesel will continue in popularity as an efficient, small capacity, reliable prime mover.

The stationary Diesel engine is usually a heavily built engine having a piston which reciprocates in a cylinder. A connecting rod is either pinned directly into a trunk type piston, or to a crosshead to which the piston is connected by a piston rod. The connecting rod bears on a crank, which has bearings in the main frame. Added to these parts are the auxiliaries such as valves and valve gear, fuel injection systems, water circulation systems, starting systems, etc. The Diesel is more

heavily built than the gasoline engine, and is a relatively slow-moving machine. Rotative speeds are commonly 100 to 750 rpm, except that automotive Diesels are designed for 2000 rpm and over. The fuel ordinarily employed is a product from crude petroleum. The low cost of good-grade petroleum fuel in the United States has, to the present time, precluded the general use of any other type of Diesel fuel. **Fuel oil** is the residue left when the distillation has removed the gasoline, kerosene, and light distillates from the crude. The heavier residues are also removed from the better grades of fuel oil. This fuel is pumped into the cylinder during the first part of the power stroke, correctly metered so that its combustion tends exactly to offset the drop of pressure which would otherwise be experienced. During combustion of the fuel in the Diesel engine the pressure remains approximately constant. After a small portion of the power stroke is completed, the fuel is cut off, and the products of combustion do work on the piston expansively.



Cross-section of Diesel engine. (*Caterpillar Tractor Co.*)

The principal and important difference between the oil and the gasoline engine resides in the method of **ignition**. Compression of the air trapped in the cylinder of a Diesel engine is employed as its means of ignition. The compression is carried to much higher pressures in the Diesel than in the Otto cycle; consequently, the temperature at the end of compression is higher in the Diesel cycle. In fact, compression is carried high enough so that the temperature of the compressed gas exceeds the ignition temperature of the fuel. This is compression ignition. It may require the volume after compression to be only one-fourteenth of that before compression, whereas it is only a fifth or a sixth in the gasoline engine. It is not possible to use compression ignition in the ordinary Otto cycle engine, because an inflammable charge is compressed, and the compression to the ignition temperature would cause spontaneous, uncontrolled, unregulated ignition. However, the charge compressed in the Diesel is fresh air—incombustible. This air is compressed until its pressure is over 500 lbs. per sq. in., and its temperature around 800° F. Then the oil is injected into the hot compressed air whose temperature is sufficiently high to cause immediate ignition of the spray.

The Diesel engine is built in both **two-cycle** and **four-cycle** types. The fuel is injected in one of two ways, either by being blown in and atomized by a high-pressure air jet (air injection), or sprayed in through a fine nozzle tip under the influence of an extremely high oil pressure created by pumps (solid injection). Thus there are four possible combinations. The slow-speed types in general use are either the two-cycle solid injection, or the four-cycle air injection. With few exceptions, high-speed Diesels are four-cycle, solid injection. Governing is accomplished by control of the fuel oil pump, more or less oil being delivered per stroke, depending on the load. For electrical generation even the multicylinder engines must be equipped with a heavy flywheel to prevent cyclic variation of speed.

A common method of starting large Diesels is by compressed air. In addition, the air-injection types require an injection air system and some airless-injection types have a scavenging air system. Both injection and scavenging air pumps are integral with the engine.

The temperatures existing in the stationary Diesel engine would soon break down the film of lubricating oil on the cylinder liners and otherwise put the engine out of service by warping of valves, pistons, etc., were the engine not cooled by circulating water through jackets surrounding the heated parts.

The heart of a Diesel engine is the **combustion chamber** end of its cylinder. The shape of the cylinder head and face of the piston, and the design of the nozzle and the injection system must be carefully considered. To obtain the complete combustion necessary to good efficiency, a fuel must be thoroughly mixed with the air charge, so that all particles of it will be burned. There must be good penetration of the oil spray into the highly compressed dense air, and there must be turbulence to insure mixing of the oil spray with the air. These two important characteristics are secured by special design, both of the cylinder head and the spray valve.

In the two-cycle engine there is no valve gear. The absence of this feature is, indeed, the virtue of the two-cycle principle. In the four-cycle engine the exhaust and inlet valves are mechanically operated from a camshaft. Since the Diesel engine is commonly rather large, the valves are correspondingly large in girth, and are operated from a massive camshaft. Although the Diesel engine is basically a slow-speed type, refinements of design, especially in the combustion chamber, have enabled builders to produce medium- and high-speed compression ignition engines. The illustration shows a cross-section of a medium-speed, four-cycle, solid injection engine. Many of its mechanical features are similar to the common automobile engine. The fuel system consists of an *injection pump* (one per cylinder), cam driven, which delivers a metered quantity of fuel oil at an extremely high pressure to an *injection nozzle*. The latter opens into a pre-combustion chamber into which some of the combustion air has been compressed. Partial combustion occurs in this chamber, then the swirling, gasified, fuel-air mixture is ejected into the main combustion chamber where nearly complete combustion will be achieved. (See **Injection, Fuel.**) (F.T.M.)

DIFFERENCE EQUATIONS. A difference equation may be described as an **equation** connecting values of an unknown **function** at two or more equally spaced values of the independent variable, as, for ex-

ample, $u(x+h) - u(x) = 2x + 1$, or $u(x+2h) + 2xu(x+h) - u(x) = x^2$.

A linear difference equation is one in which the unknown function $u(x)$ occurs linearly and the coefficients are functions of the independent variable only. A homogeneous difference equation contains no term independent of the unknown function u. (L.L.S.)

DIFFERENTIAL, AUTOMOBILE. The differential drive is an important element in the automobile. As a 4-wheel vehicle rounds a corner, the outer wheels travel a greater distance than the inner. The wheels on a wagon are mounted on a dead axle, so that they turn independently of each other. On a live axle some device which will permit them to revolve at different speeds to compensate for the difference in travel when rounding a curve is necessary. The ordinary automobile differential is illustrated in Fig. 1. The driveshaft has

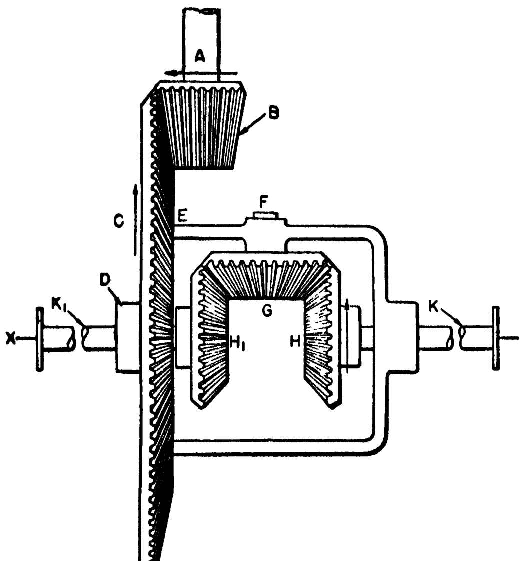


Fig. 1. Bevel gear differential.

mounted on it pinion B, which drives gear C. If it were not for the necessity of rounding curves, gear C could be rigidly fixed to the live axle KK. The differential action is obtained as follows: Gear C is not keyed to the axle. The spider E is rigidly fastened to the gear and has mounted on it, free to turn, the bevel gear G. Gear G meshes with gears H_1 and H, each of which is keyed to a half of the axle. When traveling straight ahead, gears G, H_1, and H revolve with the spider, but do not have any motion relative to each other. When rounding a curve, one wheel must travel faster than the other. The difference in rotation of the axle is compensated for by rotation of the differential gear G on its pin F. Any accelerated motion of one wheel is offset by a retarded motion of the other. (F.T.M.)

DIFFERENTIAL EQUATIONS. An equation which involves **derivatives** (or **differentials**) is called a differential equation.

If **partial derivatives** occur in the equation, it is called a partial differential equation; if not, it is called an **ordinary differential equation.** (L.L.S.)

DIFFERENTIAL HARDENING. A method of preparing printing plates or matrices used in **subtractive color photography.** The value of this process is dependent on the fact that (1) certain dyes exhibit a marked affinity for hardened gelatin as compared to unhardened gelatin, and (2) that hardened gelatin will adsorb a relatively small volume of water as compared to soft gelatin.

The first fact is made use of by employing a photographic silver image to control the position of the hardened gelatin image. This is done by treating the photographic image with a dichromate. If a film bearing such a hardened gelatin image along with soft gelatin is immersed in the proper dye bath, the dye will be absorbed by the hard gelatin in preference to the soft gelatin. The position of the hardened gelatin is, however, the original photographic silver image position. If the surplus surface dye is removed by rinsing, the dye image may be transferred to a properly treated gelatin surface by imbibition.

The other useful property of a hardened gelatin (or other colloid) image, its low water absorption, can be used in an ink-transfer process. If a film bearing the differentially hardened gelatin is soaked in water and then contacted with a greasy ink surface, the ink will adhere only to those areas containing little or no water —that is to the hardened gelatin. Such an ink image may then be transferred to a paper support. (H.C.C.)

DIFFERENTIAL LEVELING. Differential leveling is a system of surveying whereby the difference in elevation of two remote points is obtained through the use of the surveyor's **level** and **level rod.** A chain or tape is not needed. The procedure in differential leveling is illustrated in Fig. 1. BM_1 represents a known

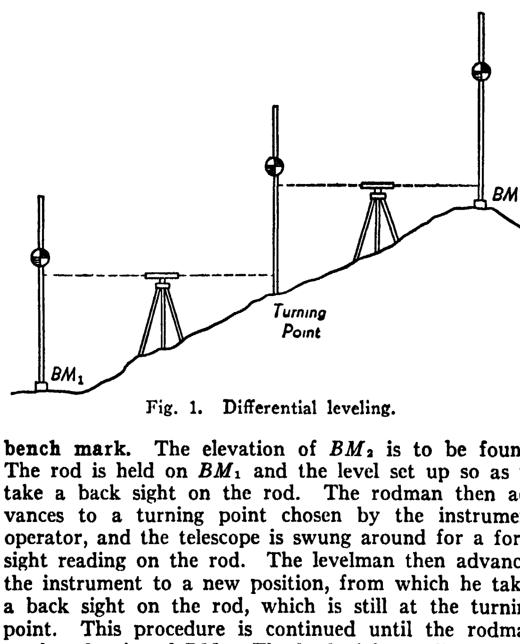

Fig. 1. Differential leveling.

bench mark. The elevation of BM_2 is to be found. The rod is held on BM_1 and the level set up so as to take a back sight on the rod. The rodman then advances to a turning point chosen by the instrument operator, and the telescope is swung around for a foresight reading on the rod. The levelman then advances the instrument to a new position, from which he takes a back sight on the rod, which is still at the turning point. This procedure is continued until the rodman reaches the site of BM_2. The back sight reading, added to the elevation of BM_1, gives the elevation of the level at the first station. The foresight reading, subtracted from the instrument elevation, gives the elevation of the turning point. In this way, by additions and subtractions of back sight and foresight readings, the total difference of elevation between BM_1 and BM_2 is determined.

The field work which is necessary for determining the elevation of points along a given line such as the center line of a railroad or highway is called profile leveling. Rod readings are taken at regular intervals and also at points of abrupt change of slope. The outline of a vertical section through the center line is called a profile. The profile is obtained by plotting elevations which are the result of profile leveling. (F.T.M.)

DIFFERENTIAL MANOMETER. A device for measuring small pressures. The device is best explained by referring to the figure. A U-tube, equipped with an

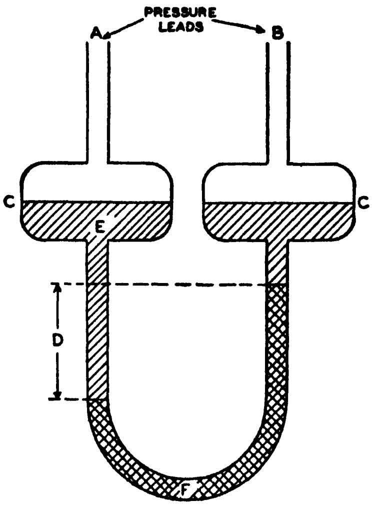

Fig. 1. Differential manometer.

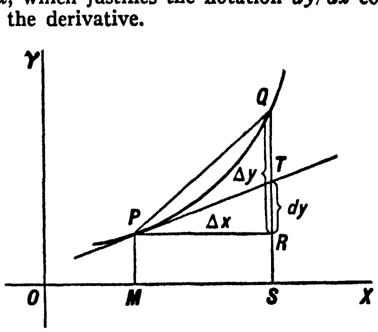
enlarged section (c) at the top of each side, has in it two immiscible liquids, a lower (heavier) liquid F and an upper (lighter) liquid E. If a pressure difference be set up across A and B, the liquid F will change position giving a head D to compensate for the pressure. Because of the enlargements in the upper tubes the top level of liquid E changes a negligible amount. The head equivalent to the pressure varies inversely as the difference between the densities of liquids E and F. By selecting the proper liquids, the difference can be made very small, making for a large head. Thus a pressure which would give only a small reading on an ordinary **manometer** can be made to produce a large reading on a differential manometer, thus increasing the accuracy of measurement. (D.E.M.)

DIFFERENTIALS. A differential is a fundamental mathematical concept closely associated with the idea of the rate of change of a function.

For a **function** of one variable, the differential is defined as follows: Let $y = f(x)$ be a given function; assign an arbitrary increment Δx to x, then the function y takes an increment Δy given by $\Delta y = f'(x)\cdot\Delta x + \epsilon\cdot\Delta x$, where $f'(x)$ is the **derivative** of y and ϵ is a variable which approaches o as $\Delta x \to 0$. Then the first term $f'(x)\cdot\Delta x$ is called the differential of $y = f(x)$, and is denoted by dy or $df(x)$. The differential of the **independent variable** x is the same as Δx, i.e.: $dx = \Delta x$; but dy is not equal to Δy, where y is the function. We may regard dy or $f'(x)\Delta x$ as an approximate value of Δy.

Since $dy = f'(x)dx$, it follows that $f'(x) = dy/dx$, so that the derivative may be regarded as the quotient of dy by dx, which justifies the notation dy/dx commonly used for the derivative.



In the accompanying figure, PT is the tangent to the curve $y = f(x)$ at the point P. Then $PR = \Delta x$, $RQ = \Delta y$, and $RT = dy$.

Since dy is an approximation to Δy, if x has a small error Δx, then Δy will be the corresponding error in y, and dy may be taken as the approximate small error in y.

The differential of a function of several variables is defined as follows: Let $u = f(x, y)$ be a function of two variables, and let x and y take arbitrary increments Δx and Δy, then the function u takes an increment Δu given by

$$\Delta u = \frac{\partial u}{\partial x}\cdot\Delta x + \frac{\partial u}{\partial y}\cdot\Delta y + \epsilon_1\cdot\Delta x + \epsilon_2\cdot\Delta y,$$

where ϵ_1 and ϵ_2 approach o as $\Delta x \to 0$ and $\Delta y \to 0$. Similarly for a function of three or more variables. The total differential of the function $u = f(x, y)$ is defined as the principal part of the total increment Δu:

$$du = \frac{\partial u}{\partial x}\cdot\Delta x + \frac{\partial u}{\partial y}\cdot\Delta y.$$

We define $dx = \Delta x$ and $dy = \Delta y$ for the independent variables. Hence

$$du = \frac{\partial u}{\partial x}\cdot dx + \frac{\partial u}{\partial y}\cdot dy.$$

Similarly for functions of three or more variables.

For the calculation of small errors in a function of several variables $u = f(x, y)$, we can use du as an approximation to Δu, so that if $\Delta x = dx$ and $\Delta y = dy$ are small errors in the independent variables, then $du = \frac{\partial u}{\partial x}\cdot dx + \frac{\partial u}{\partial y}\cdot dy$ is the approximate small error in u. (L.L.S.)

DIFFERENTIATION. In geology, differentiation refers to the general process of formation of different types of **igneous** rocks from a common parent magma.

In mathematics, the use of the term differentiation is discussed in the articles on **Derivative of the Function of a Variable**; and **Differentiation, Technique of (Mathematical)**.

In biology, differentiation is the development of the varied structures within living units through which special functions are performed. Differentiation is expressed within the **cell** in its various parts and in 1-celled organisms further differentiation gives rise to the **organelles** which carry on locomotion, digestion, and other functions. In the complex body during its development this process results in the appearance of the different kinds of cells, tissues, and organs which ultimately compose the individual. (A.W.L., R.M.F.)

DIFFERENTIATION, TECHNIQUE OF (MATHEMATICAL). General **differentiation** rules, and differentiation rules for **algebraic functions**:

1. The **derivative** of a **constant** is zero: $\frac{d}{dx}(c) = 0$.

2. The derivative of an algebraic sum of any number of functions is equal to the algebraic sum of their derivatives:

$$\frac{d}{dx}(u + v + w) = \frac{du}{dx} + \frac{dv}{dx} + \frac{dw}{dx}.$$

3. The derivative of a constant times a function is equal to the constant times the derivative of the function:

$$\frac{d}{dx}(cu) = c\cdot\frac{du}{dx}.$$

4. The derivative of the product of two functions is equal to the first factor times the derivative of the second plus the second factor times the derivative of the first:

$$\frac{d}{dx}(uv) = u\frac{dv}{dx} + v\frac{du}{dx}.$$

5. The derivative of the quotient of two functions is equal to the denominator times the derivative of the numerator minus the numerator times the derivative of the denominator, all divided by the square of the denominator:

$$\frac{d}{dx}\left(\frac{u}{v}\right) = \frac{v\frac{du}{dx} - u\frac{dv}{dx}}{v^2}.$$

6. The derivative of a constant **power** of a function is equal to the **exponent** times the function with its exponent diminished by one times the derivative of the function:

$$\frac{d}{dx}(u^n) = nu^{n-1}\frac{du}{dx}.$$

7. The derivative of a function of a function is expressed by: If y is a function of z and z is a function of x, then

$$\frac{dy}{dx} = \frac{dy}{dz}\cdot\frac{dz}{dx}.$$

8. If $x = \phi(y)$ is the **inverse function** to $y = f(x)$, then the derivatives of these two functions are **reciprocals** of each other: $\frac{dx}{dy} = 1/\frac{dy}{dx}$.

For transcendental functions, the differential rules are:

9. The derivative of the **exponential function** is given by:

$$\frac{d}{dx}(a^u) = a^u \log_e a \frac{du}{dx} \quad (a \text{ constant}),$$

$$\frac{d}{dx}(e^u) = e^u\frac{du}{dx}, \quad \frac{d}{dx}(e^x) = e^x.$$

10. The derivative of the **logarithmic function** is given by:

$$\frac{d}{dx}(\log_a u) = \frac{1}{u}\cdot\log_a e\cdot\frac{du}{dx},$$

$$\frac{d}{dx}(\log_e u) = \frac{1}{u}\cdot\frac{du}{dx},$$

$$\frac{d}{dx}(\log_{10} u) = \frac{M}{u}\cdot\frac{du}{dx}, \quad \text{where } M = \log_{10} e,$$

$$\frac{d}{dx}(\log_e x) = \frac{1}{x}, \frac{d}{dx}(\log_{10} x) = \frac{M}{x}.$$

11. The derivatives of the **trigonometric functions** are given by:

$$\frac{d}{dx}(\sin u) = \cos u\frac{du}{dx}, \qquad \frac{d}{dx}(\cos u) = -\sin u\cdot\frac{du}{dx},$$

$$\frac{d}{dx}(\tan u) = \sec^2 u\frac{du}{dx}, \qquad \frac{d}{dx}(\cot u) = -\csc^2 u\frac{du}{dx},$$

$$\frac{d}{dx}(\sec u) = \sec u\tan u\frac{du}{dx}, \quad \frac{d}{dx}(\csc u) = -\csc u\cot u\frac{du}{dx}.$$

12. The derivatives of the **inverse trigonometric functions** are given by:

$$\frac{d}{dx}(\sin^{-1} u) = \frac{1}{\sqrt{1-u^2}}\cdot\frac{du}{dx},$$

$$\frac{d}{dx}(\cos^{-1} u) = -\frac{1}{\sqrt{1-u^2}}\cdot\frac{du}{dx},$$

$$\frac{d}{dx}(\tan^{-1} u) = \frac{1}{1+u^2}\cdot\frac{du}{dx},$$

$$\frac{d}{dx}(\cot^{-1} u) = -\frac{1}{1+u^2}\cdot\frac{du}{dx},$$

$$\frac{d}{dx}(\sec^{-1} u) = \frac{1}{u\sqrt{u^2-1}}\cdot\frac{du}{dx},$$

$$\frac{d}{dx}(\csc^{-1} u) = -\frac{1}{u\sqrt{u^2-1}}\cdot\frac{du}{dx}.$$

13. For the differentiation of an **implicit function** in two variables, say $F(x, y) = 0$: differentiate each term of the equation $F(x, y) = 0$ with respect to x, regarding y as a function of x; solve the resulting equation for $\frac{dy}{dx}$. In general, the derivative $\frac{dy}{dx}$ will involve both x and y.

In terms of partial derivatives, this rule amounts to:

$$\frac{dy}{dx} = -\frac{\partial F}{\partial x}\Big/\frac{\partial F}{\partial y}.$$

14. If y is given as a function of x by means of **parametric equations:** $x = \phi(t)$, $y = \psi(t)$, then the derivative of y is given by:

$$\frac{dy}{dx} = \frac{dy}{dt}\Big/\frac{dx}{dt} = \psi'(t)/\phi'(t).$$

(L.L.S.)

DIFFERENTIATION UNDER THE INTEGRAL SIGN. For the **differentiation** of a **definite integral** of a **function** $f(x, \alpha)$ containing a parameter α, when the limits of the integral are constants a and b, we have the formula

$$\frac{d}{d\alpha}\int_a^b f(x, \alpha)dx = \int_a^b \frac{\partial f}{\partial\alpha}\cdot dx,$$

and when the limits of the integral are functions of α: u and v, we have the formula

$$\frac{d}{d\alpha}\int_u^v f(x, \alpha)dx = \int_u^v \frac{\partial f}{\partial\alpha}dx + f(v, \alpha)\frac{dv}{d\alpha} - f(u, \alpha)\frac{du}{d\alpha}.$$

(L.L.S.)

DIFFRACTION. A class of phenomena arising from the interruption of a wave-train, as of light, by one or more opaque obstacles. For example, if light from a point source passes the edge of a postcard and falls upon a white screen, the shadow of the edge is not sharply defined, but deepens to darkness gradually on one side, and is bordered by very narrow alternate bright and dark **interference** fringes (diffraction bands) on the other.

The flux density at any point P in an uninterrupted wave field is either constant or varies progressively with the position of P. But if the waves have to pass obstacles before reaching the point P, there not only will be shadows, but also the flux density at P will be subject to interference effects due to phase differences in the waves reaching it from different parts of the advancing wave front (see **Huygen's Principle**). The **diffraction grating** and the **zone plate** are dependent upon well-recognized diffraction principles.

The image of a minute opaque speck under magnification against a bright background is surrounded by concentric diffraction rings. The image of a bright object, such as a star, as formed in the focal plane of a converging lens, is also surrounded by diffraction rings. If two such images are close together the fringe systems will overlap and no matter how much magnification is applied it will never be possible to obtain clear, well-separated, images of the points. The resolving power of an optical instrument may be defined as a measure of the sharpness with which small images very close together may be distinguished. It is directly proportional to the diameter of the objective aperture and inversely proportional to the wavelength of the light.

Diffraction thus limits the resolving power, and hence the practicable magnification, of optical instruments. (L.D.W.)

DIFFRACTION GRATING. A series of very fine, closely spaced parallel slits, or of very narrow, parallel reflecting surfaces, which, when light is incident upon it at a definite angle, produces a succession of spectra. The complete optical theory is somewhat complicated, but the action of a plane transmission grating may be explained approximately as follows.

A plane, monochromatic light wave W, incident at angle i (see figure), reaches the slits at different times. A

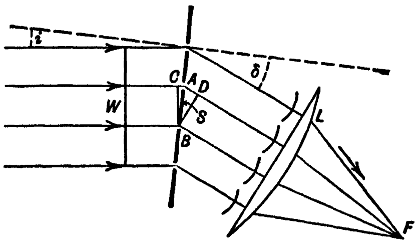


Diagram showing diffraction by a plane grating.

lens L receives the waves emerging from any two adjacent slits, A and B (among many others), after they have traveled paths differing by $CA + AD$; that is, by $S \sin i + S \sin \delta$, in which $S = AB$. If the lens is so placed that this path difference is a whole number of wavelengths, $n\lambda$, the successive wave-trains will reach it in the same phase, so that when they are brought to the focus F, they will be in synchronism and will produce a bright image of the distant source. Therefore any angle δ for which this result is possible is subject to the condition

$$S \sin i + S \sin \delta = n\lambda,$$

or

$$\sin \delta = \frac{n\lambda}{S} - \sin i.$$

Bright images will be produced for those angles δ which correspond to $n = 1, 2, 3, 4, \cdots$; the numbers denote the "orders" of the images. It is easily shown that for any order the total deviation $(i + \delta)$ is least when $\delta = i$ and therefore when $\sin \delta = \frac{n\lambda}{2S}$. If the incident light is composed of various wavelengths, the corresponding images of any order will appear at different points, since δ varies with λ; and the result is a **spectrum.** In short, the grating acts as a **dispersion** piece, and as such is of great value in **spectroscopes.**

For high dispersion the slits must be very fine and very close together (S small), and for high resolving power (sharpness of spectral lines) the total number of slits must be large. Gratings having several thousand slits to the inch of width are common. They may be made by ruling fine scratches with a diamond point on glass, or, with reflecting gratings, on polished metal. If the rulings are not spaced with absolute regularity, false lines, called "ghosts," appear in the spectrum.

Rowland was the first to rule reflection gratings on concave metal surfaces. Such gratings eliminate the necessity of the spectroscope collimator or focusing lenses, as they take light direct from the spectroscope slit and form the spectral-line images like a concave mirror. The **echelon** is another special type of grating. (L.D.W.)

DIFFUSER. A diffuser is a passage so shaped that it will change the characteristics of a fluid flow from a certain pressure and velocity to a lower velocity and a higher pressure. The diffusion must be carried out in a well-streamlined passage having smooth interior surfaces, and sides not diverging at so great an angle as to cause the fluid to leave the sides of the diffusing chamber. By reducing the velocity through increasing the cross-sectional area of flow, the pressure may be built up as the velocity head is diminished. Diffusers are applied to centrifugal **fans, centrifugal pumps,** jet pumps, **wind tunnels,** and other equipment where it is required to conserve energy by efficiently converting velocity head into pressure. (F.T.M.)

DIFFUSION OF FLUIDS. The **molecules** of a gas or of a liquid wander about ceaselessly, colliding frequently and exchanging kinetic energy, but maintaining a certain aimless progress. If an enclosure contains two gases, the lighter initially above and the heavier below, the gases at once begin to mingle because of their molecular motion. The same is true of a dense solution (as of sugar) and pure water; both the sugar and the water molecules wander across the boundary, so that in the course of time the whole body of liquid attains nearly uniform concentration. The process whereby this is effected is called diffusion. In the case of fluids of different color, its progress may be easily watched.

The rates at which different gases diffuse at a given temperature are inversely proportional to the square roots of their molecular weights. Thus, hydrogen diffuses four times as fast as oxygen. This follows, according to the **kinetic theory,** from the fact that the molecules of various kinds have the same mean kinetic energy and hence their mean square speeds are in the inverse ratio of their masses. In the case of a solution of non-uniform concentration, the diffusion of the solute from the more to the less concentrated regions takes place in accordance with Fick's law, expressed by the equation

$$\frac{dm}{dt} = -DS\frac{dc}{dx}.$$

This gives the mass of solute diffused per unit time through a cross-section S, in terms of the concentration gradient dc/dx in the direction x perpendicular to the cross-section. D is a constant for the given solute and solvent at a given temperature, and is called the diffusion coefficient. For any one pair of substances, D is found to be proportional to the absolute temperature. It should be stated that these laws apply only to non-electrolytic solutions.

Both gases and solutions exhibit selective diffusion through suitable porous partitions or membranes. Partitions may be used which will allow the smaller but not the larger molecules to pass through. There results an increase of pressure on the side where the larger molecules are. The phenomenon is called osmosis, and the osmotic pressures thus developed play an important part in many physiological processes. (L.D.W.)

DIFFUSION PUMP. Air Pumps.

DIGESTER. In the process of paper making, the wood is first reduced to chips, which are then reduced to a pulp by cooking with a solvent in a digester. In the two principal methods of chemical pulp manufacture, either soda or sulfite liquor is mixed with the chips in the digester tank in definite proportions. The whole is heated for several hours by high pressure steam. During this process the wood chips are disintegrated, freeing the cellulose for further use in the paper-making process. (F.T.M.)

DIGESTION. The process of mechanical treatment and chemical transformation by which food is prepared for absorption by the body.

The **foods** of animals consist of the complex organic materials, **proteins, carbohydrates,** and **fats.** Proteins are abundant in lean meat and in some plant products, including beans. Carbohydrates include starches and sugars and fats include both the animal fats and vege-

table oils such as occur abundantly in nuts. With the exception of a few simple sugars (grape sugar) none of these materials can be absorbed into the animal body without first being transformed into simpler compounds.

In the **digestive system** the foods are mixed with secretions containing **enzymes** which bring about the chemical changes. The mixing is accomplished by mechanical processes dependent upon muscular action. Some animals chew their food to break it up into smaller particles and others grind it in a special region of the tubular tract. Once the food enters the tubular alimentary tract of the more complex animals such as man, it is propelled and mixed by peristalsis.

The enzymes in the digestive secretions change the food by hydrolysis, a process in which molecules of food and water together are split into molecules of simpler composition. Ultimately proteins are broken up into amino acids, the carbohydrates into simple sugars, and the fats into fatty acids and glycerol. These end-products are absorbed into the tissues of the body and there used to synthesize the necessary proteins, carbohydrates, and fats, differing chemically from those originally taken in as food. (A.W.L.)

DIGESTIVE SYSTEM. The organic system which receives food and prepares it for absorption.

One-celled animals and **sponges** take food into the cell to be transformed by a process of intracellular digestion. While this process persists to a limited extent in **coelenterates**, flatworms, and mollusks (**Mollusca**), these and all other animals also have some form of digestive system or alimentary tract in which food is retained for extracellular digestion preceding absorption. Secretions are discharged into this tract by the cells of its lining and are mixed with the food. The cavity is lined with endodermal tissue, in many cases supplemented by ectodermal ingrowths at both ends.

The simplest form of digestive system is the **enteric cavity** of coelenterate **polyps.** It is little more than a sac with one opening through which food enters and undigested wastes are discharged. In the flatworms a similar condition prevails, but in both the **jellyfishes** and in some flatworms the cavity is complex, extending throughout the body in a system of canals or branches which distribute the food as well as absorb it. From the roundworms through the remainder of the animal kingdom the system is tubular, opening at one end by the mouth and at the other by the anus.

In the tubular digestive tract specialization of digestion reaches a maximum. Here food passes successively through different regions instead of being mixed indiscriminately, hence each region may subject it to special treatment. The chief regions are those which aid in securing food, simple passages, storage reservoirs, grinding structures, and digestive regions which include chambers and tubular regions. In addition, glandular derivatives of the lining are so highly developed that they become separate organs associated with the tubular tract by slender ducts.

Some of the worms have a very simple tract with a muscular **pharynx** which aids in securing food and a long simple intestine, in which it is digested. Other animals, including the leeches, insects, and birds, have a crop in which food is stored prior to digestion. The **mastax** of rotifers and the **gizzard** of birds are examples of grinding structures.

The mammalian alimentary tract is a good example of regional specialization. The oral cavity with its teeth provides for chewing and some digestion, the **pharynx** and **oesophagus** furnish a passage to the **stomach,** where food is stored and slightly digested, the small **intestine** completes digestion and absorbs the end-products, the large intestine absorbs water, and the rectum stores the remaining wastes for periodical discharge by way of the anus. Glands associated with this tract are the **salivary glands,** the **liver,** and the **pancreas.** (A.W.L.)

DIGITALIS. *Digitalis purpurea.* Foxglove. Scrophulariaceae. The foxglove is a biennial often grown as an ornamental plant. The first year of growth produces only the long basal leaves, while in the second year the erect leafy stem 2–5′ tall is developed. The flowers are borne in a **raceme** which through the bending of the **peduncles** or individual flower stalks becomes one-sided. The purple flowers have a 5-parted **calyx;** a tubular bell-shaped **corolla** obscurely five-lobed, five **stamens** and a single **pistil.** They are pollinated mainly by bees. The fruit is a 2-celled capsule.

The drug digitalis is prepared mostly from leaves of the second year's growth. These are rather coarse ovate leaves covered with glandular hairs. Decoctions of the leaves have been used in Europe for many years.

Digitalis is one of the most valued **drugs** in medicine and is used in certain kinds of **heart** disease. The chief effects it has on the heart are the regulation of its rate, rhythm, tone, contraction, and conduction of impulses.

As a crop plant, digitalis is grown in England, Germany, and in the United States, especially in Michigan. Propagation is by seeds, which are sown under glass and later transplanted. (R.M.W., R.S.M.)

DIGITATE DRAINAGE. The term applied to the finger-like pattern of stream valleys. Such a stream pattern usually develops only when the underlying formations are relatively horizontal or if folded, faulted, or **metamorphosed,** are relatively of equal hardness and solubility. (R.M.F.)

DIHEDRAL. The dihedral of an airplane measures the amount of tilt of the wings upward from a normal horizontal axis. Though the right and left wing of an airplane may, to the casual observer, appear to be rigged in a straight line, actually there is a slight angle between them. This is for the purpose of procuring lateral stability. The low-wing monoplane is inherently less stable than the high-wing monoplane or the biplane, and one will note that its wings are set at a more pronounced angle. Dihedral is measured in degrees from the normal horizontal axis to the plane of the wing. It is ordinarily from 1–4° in magnitude. (F.T.M.)

DIHEDRAL ANGLE. A dihedral angle is formed by two intersecting planes; it is measured by the corresponding plane angle formed by drawing a plane perpendicular to the intersection of the planes. (L.L.S.)

DIKE (DYKE). A tabular, intrusive mass of **igneous** rock which cuts across other igneous rock bodies, such as batholiths; or cuts across the **bedding** (stratification) of lavas or **sedimentary** formations. Not to be confused, in the chemical and mineralogical sense, with **veins;** or, in the structural sense, with **sills.** (R.M.F.)

DILL. Carrot Family.

DILUTION, DISPOSAL OF SEWAGE BY. This refers to the method of sewage disposal in which the sewage wastes are discharged into bodies of water of such extent that the natural purification processes always operative in bodies of water may dispose of the sewage wastes without the creation of a nuisance. For successful ultimate disposal all sewage wastes, liquid or solid, must undergo decomposition accompanied by active bacterial action. If there is a deficiency of oxygen present during the decomposition process putrescent conditions will ensue accompanied by the emission of foul and noxious odors and the creation of unsightly floating masses, i.e., a nuisance will be created. If ample oxygen is present the decomposition will proceed without developing the objectionable characteristics of the putrescent stage of organic decomposition.

If sufficient diluting water is provided to supply the oxygen requirements of the decomposing sewage wastes

and still leave a remainder, perhaps 40% of saturation, to support fish and other aquatic life, the sewage may be successfully disposed of by dilution; otherwise a nuisance is likely to be created.

The minimum ratio of diluting water to sewage depends primarily upon the dissolved oxygen content of the diluting water, the oxygen demand of the sewage, and the residual dissolved oxygen desired. For average conditions a fresh-water flow of 8 to 10 c.f.s per thousand population should permit successful disposal by dilution. (E.W.S.)

DILUVIUM. Derived from the Latin **diluo,** to wash apart, through **diluvialis,** flood. A relatively obsolete geologic term formerly applied to certain water-laid deposits within or bordering the glaciation regions of Europe and North America. Most of the sediments which were previously thought to have been the result of the "flood," and which are now known to be stratified **drift,** were called diluvium. In Germany, the term corresponds to our **Pleistocene.** (R.M.F.)

DIMENSION FORMULAE. Physical Magnitudes and Physical Equations.

DIMETRIC REPRESENTATION. Pictorial Representation.

DIMORPHISM. The occurrence of individuals of two forms in the same species.

In its broadest application dimorphism includes the alternation of forms such as the **polyp** and **medusa** of the **coelenterates.** It is commonly used to indicate less fundamental differences due to the conditions attending the development of essentially similar individuals. Thus some of our **butterflies** differ noticeably in the generation developed during the summer and that which emerges in the spring after passing the winter in an immature stage. This condition is seasonal dimorphism, as also is the occurrence of wet- and dry-season forms in some tropical species. Conspicuous difference between the sexes other than reproductive adaptations is sexual dimorphism. This term is also sometimes applied to the occurrence of two forms in a single sex, like the black and yellow females of the common yellow swallowtail butterfly.

The term is used by mineralogists to describe the phenomenon of certain natural compounds crystallizing in two different forms. (See **Calcite** and **Aragonite.**) (A.W.L., R.M.F.)

DINGO. Mammalia, Carnivora. A wild **dog,** *Canis dingo,* found in forested areas of Australia. It is probably descended from dogs introduced long ago.

The dingo is a serious enemy of sheep and has been killed in large numbers for its depredations. (A.W.L.)

DINOFLAGELLIDA. An order of 1-celled animals. Chiefly marine species, whose body is surrounded by an envelope of **cellulose,** often beautifully figured. **Mastigophora.** (A.W.L.)

DINOSAURS. Fossil Reptiles.

DIODE. Tube, Electronic.

DIOECIOUS. With separate sexes. Organs of only one sex developed in each individual.

There are many species of plants in which the flowers are unisexual, that is, have either stamens or pistils, but not both. If these two types of flowers occur on different plants, the plants are said to be dioecious. The willow is such a plant. (R.M.W.)

DIOPSIDE. The mineral diopside is a monoclinic pyroxene corresponding to the chemical formula $CaMg(SiO_3)_2$, calcium magnesium silicate. Its crystals, like other pyroxenes, tend to be short stout prisms of square or octagonal cross-section. Compact, granular, lamellar and fibrous varieties are often found. The prismatic cleavage is characteristic, cleavage planes intersecting at angles of 87° and 93°. A basal parting is often noted, but should not be confused with the cleavage. The hardness of diopside is 5–6; specific gravity, 3.2–3.3; uneven fracture tending toward conchoidal; luster, vitreous to dull; sometimes pearly on the base; color, light or dark greens, but may be colorless, gray, yellow or blue, although the latter color is rare. Diopside is a primary mineral in rocks like diorites, gabbros and the like, but is also found in schists, and, as the result of contact metamorphism, in such rocks as crystalline limestones and dolomites. Diopside is found in association with **vesuvianite, garnet, spinel, scapolite, tremolite, tourmaline** and similar minerals. It is a rather widespread mineral, important localities being found in the following European countries: Finland, Sweden, Switzerland, Italy; it is found in eastern Siberia near Lake Baikal. In Canada diopside localities are in Lanark and Hastings Counties, Province of Ontario, and in the United States in Lewis and St. Lawrence Counties, New York, and in Maine.

Two varieties of diopside, **malacolite** and alalite, both of a leaf-green color, have been somewhat used as gem stones. The word diopside is derived from the Greek meaning double and appearance, referring to its double refraction. Malacolite is also from the Greek, meaning soft, because of being softer than feldspar found with it.

Alalite is from the Ala Valley, in the Italian Piedmont. (E.S.C.S.)

DIOPTASE. The mineral dioptase is a rather rare **copper silicate** corresponding to the formula H_2CuSiO_4 occurring in prismatic crystals of the **hexagonal** system, tri-rhombohedral in form. It may be found in crystalline aggregates or simply massive. Dioptase displays a conchoidal to uneven fracture; hardness, 5; specific gravity, 3.28–3.35; luster, vitreous; color, a beautiful emerald green. It has been found in Russia, French Congo, Belgian Congo, South West Africa, Chile, and in the United States in Arizona. The name is derived from the Greek words meaning through and to see, because cleavage was observed by looking through the crystals. (E.S.C.S.)

DIORITE. Diorite is a deep-seated **igneous rock** composed dominantly of **sodiaplagioclase feldspar** with **hornblende, biotite,** and (or) **augite. Orthoclase** may be present in small amounts, also **quartz.** Any considerable proportion of the latter mineral produces a quartz-diorite. With increasing amount of orthoclase, we have granodiorite, which is generally understood to be a rock intermediate in character between quartz-diorite and granite. If quartz is absent and there are essentially equal amounts of orthoclase and plagioclase the rock is then known as a monzonite from the type locality, Monzoni, in the Tyrol. There are quartz monzonites and, where the deficiency of silica is great enough, nephelite monzonites. Rocks of the latter sort have been reported from Madagascar. A variety of quartz, diorite, containing both hornblende and biotite, is called tonalite from the Tonale Alps, although the rock found there is more nearly a granodiorite. The word diorite is derived from the Greek meaning distinctive or defining, in contrast to the deceptive dolerites. The diorites are of widespread occurrence. (E.S.C.S.)

DIOSPYROS EBENUM. Ebony. Ebonaceae. The ebony tree is a native of India and Ceylon. It is a large tree with entire leathery leaves and axillary flowers. The wood of the tree is divided sharply into a soft white sapwood of little value and a hard very dark heartwood. The latter is much used for inlay work,

for black piano keys, for musical instruments, and for handles of various instruments. Many other species of *Diospyros* have dark woods used as a substitute for true ebony. The wood of several other trees, especially that of the pear tree, are frequently stained to imitate ebony.

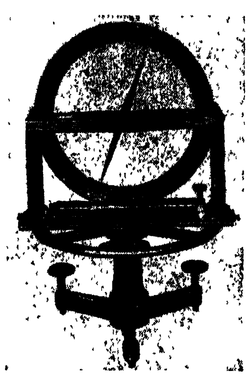
Other species of *Diospyros* are esteemed for their fruits. Especially so are *Diospyros virginiana*, the American persimmon, and *D. Kaki*, the Japanese persimmon. *Diospyros virginiana* is a large American tree, 60–100′ high, with rather thick ovate-oblong leaves and pale yellow axillary flowers. The fruit is a large globular berry an inch or more in diameter, orange-yellow in color, and very astringent until fully ripe. The astringent quality is due to the presence of much soluble **tannin**, which is gradually formed into an insoluble compound as the fruit ripens, so that the mouth-puckering quality is nearly lost. Frost action has been considered by many to be the cause of the change in the fruit. The American persimmon is hardy as far north as Rhode Island. The Japanese persimmon is a smaller tree, seldom growing more than 40′ tall, and is less hardy. Its fruits are larger than those of the American tree, and of reddish color. Both trees have a hard dark wood. (R.M.W.)

DIOTOCARDIA. An order of mollusks, mostly marine species. **Gasteropoda.** (A.W.L.)

DIP. **Anticline; Horizon.**

DIP FAULT. **Fault.**

DIP NEEDLE. More properly called an inclinometer. The instrument consists essentially of a magnetic needle poised to swing on a horizontal pivot and thus to



Dip needle or magnetic inclinometer.

indicate the "dip" or inclination of the earth's magnetic field. (See **Terrestrial Magnetism.**) The zero diameter of the vertical graduated circle should be carefully leveled and adjusted to the magnetic meridian. In order to correct for errors of level, balance, magnetization, and eccentricity, the circle should be reversed north to south, the needle axis should be reversed in its bearings, the magnetization should be reversed, and for each of these positions both ends of the needle should be read on the circle. A complete observation is thus the mean of 16 circle readings. (L.D.W.)

DIP OF HORIZON. **Horizon.**

DIPHENYL. **Hydrocarbons.**

DIPHTHERIA. An acute, contagious disease caused by the diphtheria bacillus. The organisms usually gain entry to the body through the respiratory passageways, and here they grow, multiply, and form a membrane—a thick, grayish-white exudate, which becomes necrotic. The bacteria produce a potent toxin which is liberated and absorbed at the site of the membrane; the toxin is responsible for the constitutional symptoms of the disease.

Different types of diphtheria occur, depending on whether the membrane appears in the nose, **pharynx,** or **larynx.** Nasal diphtheria is often mild; it is characterized by a bloody, yellow nasal discharge. Pharyngeal diphtheria is usually the most severe because of the large area over which the membrane may spread and the consequent rapid absorption of large amounts of toxin. Laryngeal diphtheria is dangerous because of the possibility of asphyxiation as the membrane spreads and blocks the air pathways; when this occurs, **intubation** or tracheotomy are carried out. Tracheotomy consists of incision of the trachea low in the mid-line through the neck, and insertion of a metal tube which keeps the airway open; this operation has been largely replaced by intubation, the passing of a metal tube through the mouth down past the obstruction, where it remains until the edema and membrane have receded.

The signs and symptoms of diphtheria appear after an incubation period of 5 days following exposure. Sore throat and mild fever commonly usher in the disease. The membrane may appear early and spread rapidly and may be accompanied by tremendous swelling of the neck, resulting in the so-called "bull neck." In the laryngeal form, cough and noisy, difficult respirations occur. The severity of the constitutional symptoms depends on the amount of toxin absorbed. In a severe pharyngeal type, prostration may be extreme, and death may occur within several days.

Great advance in the treatment of diphtheria came with the development of a specific antitoxin which neutralizes the circulating toxin. (See **Serum.**) The mortality has been cut from 35% (90% in the laryngeal form) to 5%. If the antitoxin is given early, and in large amounts, the prognosis is good even in the most severe cases. The effect on the local reaction can be observed within 24 hours of administration: the membrane stops spreading, the swelling diminishes, and the patient's constitutional signs improve markedly also.

In spite of adequate treatment and recovery from the acute phase of diphtheria, late complications due to the effects of the toxin may occur; early treatment, however, does cut down their incidence. The commonest late complications are peripheral **neuritis** which may progress to paralyses, and acute **inflammation** of the heart muscle, which may be severe enough to cause **heart failure** and death. These occur usually in the second or third week after onset of the disease. The neuritis heals without treatment, although the period of recovery may extend over several months; the same is true of the heart lesion except in those cases which are fatal in the first few days after the development of cardiac symptoms.

The control of diphtheria has been one of the most successful programs in modern medicine. This has been accomplished by the immunization of the susceptible population, i.e., young children, with small doses of inactive toxin. The incidence of the disease in children has been cut down tremendously, and the cases now occurring are more often in the young adult population. This group represents individuals who have never been immunized, or who have lost their immunity over a period of years. The Schick test is used to detect susceptible individuals: a minute amount of toxin is injected into the skin, and the site is observed for the appearance of redness and swelling. If the person tested is immune, the antitoxin in his blood will neutralize the injected toxin, and no reaction will occur; but if he is susceptible, the reaction will appear and persist for several days. Shick positive individuals are then immunized.

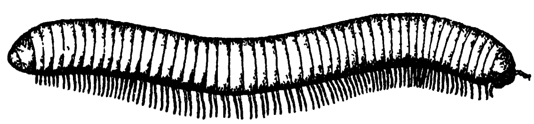
Diphtheria **carriers** represent a public-health problem, since they may harbor virulent diphtheria organisms in their throats and nasal passageways, and spread the disease through a community. It is often difficult to correct the carrier state. (D.M.H.)

DIPLEURULA. A bilaterally symmetrical **larva** of the **echinoderms.** It is formed from the **gastrula** by the breaking through of a depression to form the mouth and by the assumption of a form peculiar to the several classes, usually with projecting lobes. The cilia of the outer surface become arranged in a band in most classes. The **auricularia, bipinnaria,** and **pluteus** are forms of dipleurula larvae. (A.W.L.)

DIPLOBLASTIC. Derived from two embryonic germ layers. The first step in the formation of tissues in the developing multicellular animal is the formation of two layers, one covering the outside of the body and the other lining a cavity within it. These are the ectoderm and endoderm, respectively. The bodies of **sponges, coelenterates,** and possibly **ctenophores** develop by the further differentiation of these two layers alone. (A.W.L.)

DIPLOPODA. The millipedes. A class of the phylum **Arthropoda.**

Millipedes are worm-like animals with a head and segmented body. Each segment bears two pairs of legs, ex-



Millipede.

cepting the first and last few. The head bears a pair of antennae and in some species a pair of eyes. Most millipedes have a cylindrical body.

These animals live in moist places, usually among rubbish on the surface of the ground, and eat decaying organic matter or plant tissues. Some attack roots and are therefore of economic importance.

The class is divided into two orders, Pselaphognatha and Chilognatha. All common species belong to the latter. (A.W.L.)

DIPLOSOME. (See **Cell.**) A centrosome with two centrioles. (A.W.L.)

DIPNOI, DIPNEUSTI. The lungfishes. An order of the class **Pisces** made up of a few species found in Australia, Africa, and South America. They have an air sac opening from the **pharynx** which serves as a lung.

These fishes live in marshes and intermittent streams. When the water becomes stagnant they thrive by breathing air at the surface and when it dries up completely they form cells in the mud at the bottom with a vent leading to the surface and lie dormant until the pond is renewed. (See also **Fossil Fishes.**) (A.W.L.)

DIPPER. Aves, Passeriformes. The water **ouzel.**

DIPSOMANIA. Inordinate and uncontrollable drinking usually due to a chronically disturbed state of the mind or personality which causes the individual to have constant recourse to alcohol. It is almost always a conscious or unconscious attempt to obtain forgetfulness or escape from the realities or failures of life. (R.S.M.)

DIPTERA. Flies, mosquitoes, midges, gnats and other **insects.** An order characterized by sucking and sometimes piercing mouths and the presence of a single pair of wings. The hind wings are represented by the halteres, slender clubbed appendages, often inconspicuous. A few species lack wings. The metamorphosis is complete and the larvae of many species are known as maggots.

This is one of the largest orders of insects, with about 50,000 described species, and in variety of adaptations it is exceeded by no other. Some species suck the juices of plants, some eat the tissues during larval life, some visit flowers for nectar, some suck blood, some are parasitic inside or outside the bodies of warm-blooded animals, and many are parasitic on other insects or are predacious. Many are scavengers, living on decaying organic matter or on the wastes of animals.

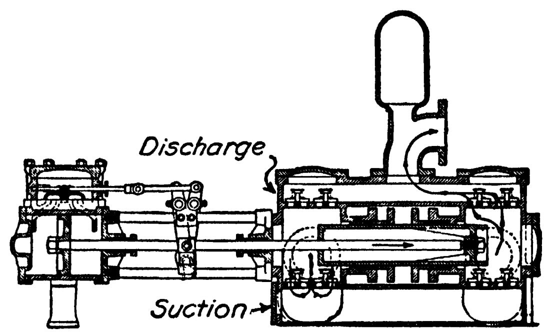
Species of economic importance include some of the plant-feeders, such as the **Hessian fly,** the blood-sucking **horse flies** and **mosquitoes,** and the parasitic **bot flies.** (A.W.L.)

DIPTERUS. Fossil Fishes.

DIRECT MOTION. Planetary Motion.

DIRECT STRESS. Stress.

DIRECT-ACTING PUMP. The direct-acting pump is a steam-driven **pump** of the piston and cylinder type, not having crankshafts, flywheels, or similar rotative apparatus. It is a simple, inexpensive, and reliable piece



Direct-acting pump.

of equipment—but inefficient as a pumping unit. However, as the heat of the exhaust steam can often be recovered in feed water the low thermal efficiency is not of much importance. In construction it consists of steam and water cylinders, the pistons of which are rigidly connected by a pump rod. The steam piston must have a larger diameter than the water piston when the pump is used in boiler feed service. If p is the boiler gauge pressure, p_h the static plus friction head on the water end, p_f the friction drop in the steam pipe, $A_w p_l$, the pounds excess push required to overcome pump friction, water inertia, etc., A_w, D_w, A_s, D_s area and diameter of steam and water pistons:

$$\frac{D_s}{D_w} = \sqrt{\frac{p + p_h + p_l}{p - p_f}} \text{ (all } p\text{'s being expressed in lbs./sq. in.)}$$

p_l involves the design and operating characteristics of the pump. In order to insure ample operating pressure D_s/D_w is made large enough to include considerable margin of reserve, being about 1.6 for ordinary boiler feed service and 2.5 for low-pressure feed service. Control of capacity is exercised through speed variation by throttling the steam line (i.e., adding a throttle pressure drop to p_f). In practice, units are rated at maximum piston speeds of 100 ft. per min., but should actually be operated at between 25 and 40 strokes per min. The pulsation of delivery is absorbed by an air compression chamber placed in the discharge line.

The direct-acting steam pump consumes from 100 to 300 lbs. of steam per horsepower hour. Thermal efficiency is so low as to have no comparative meaning and in its place is substituted pump duty; that is, the foot

pounds work done in the pump cylinders per million B.T.U. chargeable to the steam end. The high steam consumption is caused by non-expansive use of the steam. Were the steam expanded the pump would stall before reaching the end of its stroke unless the ratio D_s/D_w were extremely large and a flywheel provided to steady the speed. (F.T.M.)

DIRECT-CURRENT CIRCUITS. Unidirectional current is produced from batteries, from dynamo machinery equipped with **commutators**, or by means of **rectifiers**. The great disadvantage of d.c. is the fact that until recently it has not been commercially expedient to transform it from low voltage to the high voltage necessary for long-distance transmission of electrical power. Difficulties of **commutation** prevent generation at high voltages. Recently the use of electron tubes, such as the **thyratron**, has opened up new transmission possibilities for d.c.

In lighting and heating apparatus there is not much difference between d.c. and a.c. D-c **motors** are more expensive than a-c of equivalent power rating, but they have better operating characteristics and simpler speed control. Inductance and capacitance are not important factors in d-c transmission.

The basis for most d-c circuit calculations is **Ohm's Law.** For practical purposes Ohm's Law may be stated:

$$E = IR \text{ volts.}$$

E is the voltage drop across the resistance of R ohms when I amperes flow. If conductors are connected in series, the over-all resistance of the circuit is the sum of the resistances of the separate conductors. If, however, they are connected in parallel, the reciprocal of over-all resistances is obtained by summing the reciprocals of the individual resistances. Therefore, adding more wires in series increases the over-all resistances of the conductors, but decreases it if they are connected in parallel. In any complex d-c network, it will always be true that, first, the sum of currents flowing to a joint will equal the sum of currents flowing away from that joint; second, the algebraic sum of the e.m f.'s in any circuit will be equaled by the sum of the voltage drops in that same circuit. The electrical power flowing in a d-c circuit is found by multiplying the voltage by the current, the unit of power being watts. Heat which is generated by electrical current flowing through a resistance of R ohms for T seconds is:

$$\text{Heat} = I^2RT \text{ watt-seconds.}$$

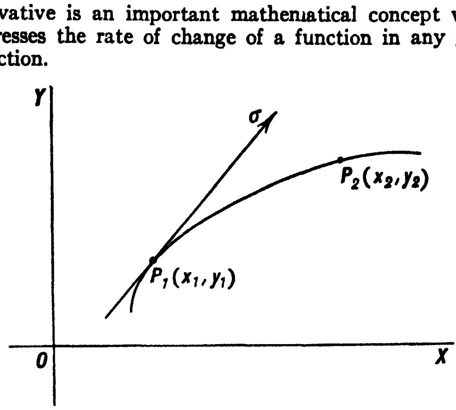
The watt-second is a unit of electrical energy so small that 1055 watt-seconds are required to equal one B.T.U. (See **Electric Circuits.**) (F.T.M., L.R.Q.)

DIRECTION. The term direction is used in **navigation** to describe the angle between **north** and any given line. The modern practice is for navigators to express directions in degrees of angle measured from the north to the right (i.e., through the east) through 360°. The standard practice is to use three digits for expressing directions. For example, a direction 4° east of north is expressed as 004°, east is expressed as 090°, west as 270°, etc. Several approximate methods for expressing the directions of bearings are in use by lookouts on ships, by aviators, and in cases where rapid description of approximate direction is desired. (See **Bearings, Azimuth.**) (W.K.G.)

DIRECTION COSINES OF A LINE IN SPACE. Let a set of **rectangular coordinate** axes in space be chosen, and let l be any line in space. Through the origin O of the coordinate system draw a line l' parallel to the given line l. Let α, β, γ be the angles which line l' makes with the X-, Y-, Z-axes respectively. Then these angles α, β, γ are called the direction angles of the given line l, and $\cos \alpha$, $\cos \beta$, $\cos \gamma$ are called the direction cosines of the line l. (L.L.S.)

DIRECTIONAL ANTENNA. For ordinary radio-broadcast service it is desirable to transmit the radio signal in all directions equally, but for special broadcast services such as international short wave, it is often desirable to direct the radiation in some specific direction and avoid radiation in other directions. The need for directed radiation is even more pronounced in other types of radio service. The radio signals may be directed by the use of directional antennae, or, as often called when consisting of more than one element, directional arrays. Any **antenna** is directional to a certain extent, e.g., the common tower antenna for broadcast stations does not radiate directly upward, but in the sense used here a directional antenna is one having marked characteristics of this type. Basically the directional antennae all depend upon radiation from two or more components adding vectorially (see **Alternating-Current Circuits**). If the waves radiated from various elements add in a certain direction the signal will be strong in that direction, while if they tend to cancel, or subtract, in a given direction the signal will be zero or weaker in that direction. One of the simplest directional antennae is the loop such as used with many portable receivers. Here the two elements whose effects add vectorially are the two vertical sides of the loop. The result is a figure 8 radiation pattern, i.e., if lines are drawn to scale in various directions so their lengths represent the strength of the signal in each direction, the ends will all lie on a figure 8 curve with the antenna at the center. These antennae are used for many **radio ranges**, and, since the directional characteristics of any antenna are the same for transmission and reception, for **radio compass** use. The directional pattern may be altered by adding the radiation from a separate vertical antenna. For broadcast use where it is necessary to cut down the signal in certain directions, usually to avoid interference with another station, systems consisting of two or more vertical antennae are quite common. By proper spacing of the elements and proper choice of the phase of the currents (which can easily be adjusted by circuit values) a wide range of radiation patterns may be obtained. For international short-wave broadcasts and for point-to-point communication more elaborate extensions of this same principle are used. Since the more elements in an array, the sharper the pattern, the radiation may be beamed at will, the type service and the economics being the usual limiting factors. By stacking systems one above the other in a vertical plane the radiation may be directed vertically as well as horizontally. It should be mentioned that it is not desirable to have the beam too sharp even for point-to-point service since the variations in the **ionosphere** may cause the signal to miss the receiver if the beam is too sharp. Sometimes the elements of an array are not all fed directly from the transmitter, but some are fed and others pick up energy radiated by the first and reradiate it. By proper choice of the spacing and the antenna dimensions these various radiations may be made to give the desired pattern. The fed antennae are often referred to as driven antennae or elements and the others as parasitic antennae. There are many other types of directional antennae, such as rhombic, V, herring bone, etc., but all depend upon vector addition of the radiation to give the pattern. By the use of directional arrays the signal transmitted in a given direction may be increased manyfold over its value for the same transmitter with a non-directional antenna. A measure of this is the gain of the array which is the signal with the array divided by the signal in the same direction for one element of the array serving as antenna. Where the type service permits their use, directional arrays are the most economical means of obtaining increased signal strength at the receiver. In reception the directional antenna allows the reception of a signal from the desired direction and suppresses signals and noise from other directions. (L.R.Q.)

DIRECTIONAL DERIVATIVES. A directional derivative is an important mathematical concept which expresses the rate of change of a function in any given direction.



Let $u(x, y)$ be a **continuous function** in a region S of the plane, let $P_1(x_1, y_1)$ be a fixed point in S and let C be a curve passing through P_1. Take another point P_2 on C, and let $\Delta u = u(x_2, y_2) - u(x_1, y_1)$. Let ΔS be the arc P_1P_2 of the curve C, and form the ratio $\frac{\Delta u}{\Delta s}$. Let the point P_2 approach the point P_1 along curve C, so that $\Delta s \to 0$, then the **limit**

$$\lim_{\Delta s \to 0} \frac{\Delta u}{\Delta s}$$

is called the directional derivative of u at the point P_1 along the curve C. If σ is the direction of the **tangent** to C at P_1, then the above limit may also be called the directional derivative of u at P_1 in the direction σ. The usual notation for this directional derivative is either $\frac{\partial u}{\partial s}$ or $\frac{du}{ds}$.

This directional derivative may be evaluated in terms of **partial derivatives** by the following formula:

$$\frac{\partial u}{\partial s} = \frac{\partial u}{\partial x}\cos\alpha + \frac{\partial u}{\partial y}\sin\alpha,$$

where α is the inclination angle (with the X-axis) of the direction σ in which the derivative is taken.

The directional derivative of a function $u(x, y, z)$ of three variables in any direction in space may be defined in a similar way. For such a derivative we have the following formula:

$$\frac{\partial u}{\partial s} = \frac{\partial u}{\partial x}\cos\alpha + \frac{\partial u}{\partial y}\cos\beta + \frac{\partial u}{\partial z}\cos\gamma,$$

where α, β, γ are the **direction angles** of the direction σ in which the derivative is taken.

The directional derivative of a function $f(x, y, z)$ at a given point in the direction of the normal to the surface $f(x, y, z) = c$ (a constant) through this point is called the normal derivative of f, and is denoted by $\frac{\partial f}{\partial n}$ or $\frac{df}{dn}$. It is the greatest value of the directional derivative in any direction. (L.L.S.)

DIRECTRIX OF A CONIC. **Conic Sections.**

DIRIGIBLE. **Airship.**

DISACCHARIDES. **Carbohydrates.**

DISCHARGE, GASEOUS. The gaseous discharge is the basis of operation of many of the electron tubes in common use. If two electrodes have a gas at low pressure between them and a gradually increasing voltage is applied across them, a series of events takes place as the voltage is raised. First a very small current, of the order of microamperes, will flow as the ions and electrons are attracted to the electrodes. These charged particles are present because various cosmic radiations, radioactive radiations, etc., which are always present except in specially shielded enclosures, ionize the gas molecules. As the voltage is raised the current finally begins to increase rapidly because the electrons being attracted towards the positive electrode have gained sufficient energy to ionize atoms of the gas and thus generate more carriers of the current. Suddenly the current increases extremely rapidly, and at the same time the voltage across the tube drops. The value of the voltage at which this occurs is the breakdown voltage and the gas has broken into a self-maintaining discharge called a glow. If the current is not limited by circuit resistance it continues to increase, almost instantaneously, while the voltage drops to a low value and the discharge becomes an **arc.** If the circuit has insufficient resistance the current will reach an enormous value with probable damage to the tube and other circuit elements. The glow discharge is characterized by the ability to pass moderate currents at moderate values of voltage, while the arc will pass very large currents at low values of applied voltage. (L.R.Q.)

DISCONFORMITY. The geological meaning of this term is treated under **unconformity.**

DISCONTINUITY OF A FUNCTION. **Continuous Function.**

DISCONTINUITY SURFACES. **Fronts.**

DISCRETE VARIABLE. A discrete **variable** is one which occurs only in terms of integral values of a certain unit. Examples are the number of votes cast in an election, or the number of Beta particles emitted by a radioactive substance. A variable which is not discrete is said to be continuous. (L.A.A.)

DISCRIMINANT OF A QUADRATIC EQUATION. **Quadratic Equations in One Unknown.**

DISCRIMINATOR. This is the detector (see **Detection**) for a frequency modulation receiver. In frequency modulation the intelligence is impressed or modulated upon the **carrier** by causing variations in frequency. However, our **loud-speakers** operate upon a change of magnitude of the current through them so some method must be provided in the frequency modulation receiver to convert the frequency variations into amplitude variations. This is the function of the discriminator. It is a special type of balanced rectifier or detector which gives no output at the frequency for which it is tuned (the carrier frequency), but gives an output voltage whose magnitude and polarity are determined by the amount and direction of the frequency deviation of the input signal. As the received signal is varied back and forth in frequency by the **modulation,** the discriminator gives an output voltage whose magnitude follows these frequency changes. This output voltage may then be amplified and used to drive the loud-speaker. The discriminator is also used with appropriate circuits to tune automatically **receivers** having automatic frequency control. It is used in certain frequency modulation transmitter circuits as part of the frequency-stabilizing circuit. (L.R.Q.)

DISEASES OF PLANTS. Plants are attacked by a great many diseases. A plant disease may be defined as any variation from a normal condition, either in structure or function. Disease may be due to an unfavorable environment, one lacking in water or in the mineral requirements of the plant, or to attacks by various organisms. Among the many agents which cause diseases in plants are **bacteria** and **fungi,** and many animals, as well as the **viruses.** The results of infection are many and varied. Often the afflicted plant is stunted, its leaves

become wrinkled and irregular, and the normal green color spotted or mottled with white or yellow patches. Parts may die and drop off. Again, various abnormalities, such as **galls** and **witches' brooms**, may be formed.

If the disease is caused by a fungus or a bacterium, the disease-causing organism must gain entrance into the plant. There are many ways in which this may occur. The older stems of higher plants are covered by a thick layer of cork cells, the walls of which become suberized (see **Suberin**). The leaves and young stems are protected by a thinner epidermal layer of cells, the outer surface of which is often further protected by a layer of cutin. In the epidermis of the leaf, however, there are many minute openings or **stomata** through which gases pass. In the outer layer of stems there are lenticels, masses of loosely packed cells which permit a ready movement of gases from the outer air into the stem. Through these openings disease-causing organisms may enter the plant. A fungous **spore**, falling onto a leaf, germinates if moisture is available, and pushes out a slender tube or hypha which grows through a **stoma** into the body of the leaf. There conditions are more favorable, and the fungus grows rapidly, spreading through the leaf.

But entrance to the plant is more frequently through accidental openings. A branch is broken off, or bruised. Sucking insects or other organisms make a puncture through the outer layers. In any case, a favorable condition is then established for the rapid growth of the disease-producing organism. Careless pruning often provides the means of entrance for disease.

In many cases the growth of the parasite causing the disease is very slow. Years may elapse before the real damage appears. On the other hand, in some diseases the infection spreads rapidly and soon shows its presence. The spores or cells which cause disease are formed in immense numbers. They are of small size and easily carried about by wind or by water, and deposited everywhere. Only chance brings them to a suitable host. Insects also carry disease-producing organisms from one plant to another. In this stage these organisms are extremely resistant to adverse conditions around them and usually able to live unharmed for long periods of time. When conditions around them become favorable, infection quickly follows. One of the most important requirements is moisture. When moisture is abundant, therefore, epidemic outbreaks of the diseases may occur.

There are many ways of combating these various diseases. First among these is prevention. Since mechanical injury offers a means of entrance, it should be avoided as much as possible. When such injury is necessary, as in pruning, care should be taken to cover the cut surfaces with protective substances. Another means of combating disease is by spraying, spreading over the plant a film of substance which is toxic to the disease-causing organisms. Not only may most insects be controlled by this means, but also the growth of many fungi may be inhibited. Bordeaux mixture, sulfur dust, and many different chemical mixtures are much used in controlling fungous pests. Once a plant has become infected it becomes necessary to remove the infected part and destroy it, or to destroy the entire plant, to prevent the disease from spreading to other plants.

In recent years a new method of combating disease has been utilized. This is based on the observation that many plants, even of susceptible species, become immune. If the plant is a perennial and the disease attacks only one part, it is possible to graft resistant forms onto the plant. An example of this treatment is found in the European grape. The roots of the European grape are attacked by the **Phylloxera** insect, and succumb rapidly. This pest threatened to wipe out the grape industry of Europe. The American grape resists the insects, so that by grafting European grape stocks onto American roots, the disease was controlled and the industry saved. Another method is to breed immune strains by selecting resistant plants and crossing them with plants of desirable quality, but poor resistance. By selection among the offspring of such a cross a new form may be developed which combines the resistant quality of one plant with the superior or desired qualities of the other. Nature itself seems to develop such resistant varieties. Often one may use such naturally immune plants directly.

Among the commoner diseases of plants are fire-blight, also called pear blight, caused by *Bacillus amylovorus,* a bacterium which attacks the **cambium** and inner bark. The disease is spread by insects. It causes the leaves, blossoms and young twigs to wilt and turn dark-colored as though damaged by fire. Citrus canker, caused by *Pseudomonas citri,* is another bacterial disease. It attacks various citrus plants, causing brown spots to appear on leaves, young shoots and on the fruit. Apple scab is a widespread disease of the apple trees. The organism causing the disease is an **ascomycete,** *Venturia inaequalis,* introduced into this country from Europe. The fungus grows on the leaves and fruit, forming small grayish spots which become scab-like. The fungus hyphae grow in the tissues just beneath the epidermis, spreading slowly. The parasite survives the winter on fallen leaves or on the young twigs. Another common and widespread disease is black knot of plum trees. It is caused by an **ascomycete,** *Plowrightia morbosa,* which attacks the **cambium, phloem** and cortical tissues of young twigs. The presence of the fungous **mycelium** stimulates the tissues of the plum to increased growth, forming conspicuous black warty growths. These may develop on one side of the stem only, in which case the branch continues to grow and fruit, or the warty growth may completely surround the stem, causing its death. Ergot, caused by an **ascomycete,** *Claviceps purpurea,* is a disease of rye and other grasses. The fungus grows in the young ovary, forming a dense mass of **mycelium** which replaces the ovary tissues and causes a pronounced hypertrophy of the ovary. Later the fungus forms hard, black, horn-like bodies which project from the **glumes** of the **floret.** These black bodies are called sclerotia, or ergot spurs. It is through them that the fungus survives the winter. In the spring the sclerotium develops a brownish outgrowth with an enlarged tip. In this tip flask-shaped cavities called perithecia are formed. In them the asci each containing eight ascospores are found. From these ascospores conidia are cut off. These conidia may infect developing rye ovaries. Ergot spurs are very poisonous, causing serious trouble when eaten by cattle. The animals suffer from grave digestive disturbances, and, in severe cases, serious impairment of the nervous system and a sloughing off of hoofs, and loss of teeth and hair. Bread made from ergot-infested rye causes similar effects in human beings. Ergot is used medicinally.

Other important plant diseases are caused by **rusts** and **smuts.** (R.M.W.)

DISHED HEAD. Pressure Cap.

DISINFECTANT. Any agent, physical or chemical, which destroys infective organisms. (R.S.M.)

DISK GRINDER. Grinding.

DISLOCATION. The displacement of any part from the normal position. This term is used especially in reference to the **joints** of the body. In a compound dislocation, a joint is penetrated by a wound. In a fracture dislocation, there is a fracture existing with the dislocation. A traumatic dislocation is one that is caused by violence. (R.S.M., D.M.H.)

DISORIENTATION. A confused state of mind in which the normal relationship of identity, time and place is lost. (R.S.M.)

DISPERSION. The selective deviation of an emission in accordance with some variable characteristics; such as the refraction of light at different angles for different frequencies. When an emission is so dispersed, the result is a **spectrum.**

The dispersion of light may be accomplished through **refraction** by a **prism, diffraction** by a grating, or other means. Refractive dispersion is due to the fact that the velocity of light in a given medium, and hence the **refractive index,** vary with the frequency. In any case, if the deviation Δ produced by the dispersing apparatus is expressible as a function of the wave length λ, then the measure of the dispersion may be taken as $D = \frac{d\Delta}{d\lambda}$. For example, for a plane **diffraction grating** at normal incidence, the deviation in the first order is given by $\sin \Delta = \lambda/s$, in which s is the grating space; from which it follows that the dispersion is $D = (s^2 - \lambda^2)^{-1/2}$.

Refractive dispersion is not so simply expressed. For a single refraction at angle of incidence i and with refractive index n, it may be shown that the dispersion $d\Delta/d\lambda$ is equal to

$$D = \frac{\sin i}{n\sqrt{n^2 - \sin^2 i}} \cdot \frac{dn}{d\lambda}.$$

Various attempts have been made to express n as a function of λ, for example, by the empirical dispersion formula of Cauchy:

$$n = A + \frac{B}{\lambda^2} + \frac{C}{\lambda^4} + \cdots;$$

or by that of Sellmeyer (see **Anomalous Dispersion**):

$$n = 1 + \frac{A\lambda^2}{\lambda^2 - \lambda_1^2} + \frac{B\lambda^2}{\lambda^2 - \lambda_2^2} + \cdots.$$

Different media are commonly compared through some arbitrarily defined "dispersive power"; such as $(n_F - n_C)/(n_D - 1)$, in which the n-terms are subscripted to indicate the refractive indices for the F, C, and D **Fraunhofer lines.**

In statistics, dispersion is that property of a distribution indicating the spread of the items of the distribution. If the **variates** are very much alike, we say the dispersion is small. If the items are very different or very dissimilar, we have a large amount of **variability.** Measures of dispersion are the **variance,** the **standard deviation,** the **average deviation,** and the **range.** Two distributions may have exactly the same mean, but may differ in their standard deviations. The variance or the standard deviation is the preferred measure of dispersion. (L.D.W., L.A.A.)

DISPLACEMENT. Displacement in a piston and cylinder mechanism is the volume swept out by the piston face. It is assumed that the face of the piston is coplanar. Given the bore and stroke as D and L, the number of cylinders n, the displacement is:

$$\frac{\pi D^2 Ln}{4}.$$

The portion of a ship which is immersed displaces a certain weight of water. According to Archimedes' principle, a body immersed in water is buoyed up by a force equal to the weight of water displaced by the body. Hence the displacement of a ship in tons of water is equal to the weight of the ship and of its contents. (For electric displacement, see **Dielectrics.**) (F.T.M.)

DISPLACEMENT CURRENT. Electric Currents.

DISPLACEMENT LAW. Wien's Laws.

DISSEMINATION OF SEEDS. Fruit, Seed.

DISSEPIMENT. A partition or septum. (A.W.L.)

DISSOCIATION. For electrolytic dissociation see **Electrochemistry** and **Reactions Involving Recombination of Ions;** for thermal dissociations see **Equilibrium; Association and Polymerization.** See also **Rockets.**

DISSOLVING. The limiting amount of a gas or solid dissolving in a liquid at a given temperature and pressure is termed the solubility. (See **Solutions and Solubility.**) The method of attaining the limit is to expose the liquid, which is generally water, to the gas or solid for a sufficient length of time, until no more of the gas or solid dissolves at the given temperature and pressure. In order to make the time as short as possible, vigorous mixing of the solution is demanded and a relatively large surface of contact between the gas or the solid and the solution.

These ends are accomplished in the case of a gas by the use of the principle of countercurrent flow, by which the gas is passed first through the almost saturated solution, consecutively thereafter through less and less saturated solution, and finally through the pure solvent. The gas is commonly introduced at the bottom of a tower into the top of which the solvent is fed. The tower may be charged with inert material or contain bubbling plates to furnish the desired large surfaces of contact and the mixing. **Ammonia, hydrogen chloride, sulfur dioxide, carbon dioxide** are common soluble gases which are subjected to such a process. The process of dissolving one gas from a gas mixture is often called scrubbing. The liquid or solution used in scrubbing may be one with which the gas reacts chemically.

The solution of a solid is accomplished by allowing the liquid or solution to pass over a sufficient surface of the solid, or the solid is suspended in the upper part of the liquid, in which case the solution as formed being itself denser than the liquid, descends and allows fresh contact.

An interesting application of dissolving on a large scale is that in which the sulfite liquor is prepared for cooking wood chips to pulp for **paper.** A tower, sometimes about 100′ in height, is charged with lumps of **limestone** (calcium carbonate). Water is run into the top of the tower, flows down over the limestone, meets sulfur dioxide which enters at the bottom, and the resulting solution of **sulfurous acid** dissolves the limestone in the lower portion. Carbon dioxide gas passes out at the top of the tower, and the cooking solution, consisting of **calcium hydrogen sulfite** and sulfurous acid, is recovered at the bottom.

The heat change accompanying solution is characteristic of the substances. Specific examples are given in the following table. For solubility of the gases listed see **Solutions and Solubility.**

Gas		Upon Dissolving	Heat Evolved in Gram-calories
Ammonia	17	grams in 200 × 18 grams water	8,460
Hydrogen chloride	36.5	" " 200 × 18 " "	17,440
Sulfur dioxide	64	" " 300 × 18 " "	8,550
Carbon dioxide	44	" " 300 × 18 " "	4,760
Solid			
Sodium hydroxide	40	" " 200 × 18 " "	9,940
Sodium chloride	58.5	" " 100 × 18 " "	−1,180
Sodium nitrate	85	" " 200 × 18 " "	−5,030
Sodium sulfate decahydrate	322	" " 400 × 18 " "	−18,760

Heat is evolved upon solution of all gases. Heat is absorbed upon the solution of the majority of solids. (The heat of solution in an almost saturated solution is negative in the case of solids whose solubility increases with increase of temperature.) (R.K.S.)

DISTILLATION, EVAPORATION, AND DRYING. Distillation, evaporation, drying, sublimation are processes that involve the vapor pressure of liquids. The **vapor pressure** of a given pure substance is a constant varying with temperature. In a solution of two or more liquids, the vapor pressure of each concentration ratio is definite. Many systems have been studied. For the separation of two liquids in solution, use is made of the fact that the ratio of the two substances in the vapor and liquid phases is usually different.

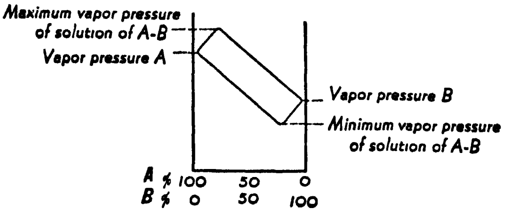


Fig. 1. Diagram showing vapor pressure relations of a solution of two liquids.

SYSTEM: ETHYL ALCOHOL-WATER
Total Pressure, 760 mm.

Mol Percent in Liquid Phase		Temperature of Volatilization, °C.	Mol Percent of Ethyl Alcohol in Vapor (and, therefore, in condensate)
Ethyl Alcohol	Water		
0	100	100	0
1.90	98.10	95.5	17.00
7.21	92.79	89.0	38.91
12.38	87.62	85.3	47.04
26.08	73.92	82.3	55.80
39.65	60.35	80.7	61.22
51.98	48.02	79.7	65.99
67.63	32.37	78.7	73.85
89.43	10.57	78.15*	89.43

* Minimum boiling-point mixture.

EFFECT OF CHANGE OF PRESSURE ON BOILING POINT AND COMPOSITION OF DISTILLATE OF CONSTANT MINIMUM BOILING-POINT MIXTURE OF ETHYL ALCOHOL-WATER

Constant Minimum Boiling-Point Mixture, °C.	Pressure, mm.	Mol Percent of Ethyl Alcohol
78.15	760	89.43
62.8	400	91.4
87.8	1100	89.3

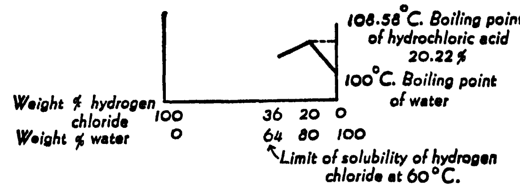

Fig. 3. Diagram showing boiling-point relations of hydrochloric acid solutions.

Constant minimum boiling-point mixtures are also known of the systems: **ethyl alcohol-carbon tetrachloride**, ethyl alcohol-**carbon disulfide**, ethyl alcohol-**chloroform**, isopropyl **alcohol-water**, isopropyl alcohol-chloroform, **acetone-methyl alcohol**, etc.

SYSTEM: HYDROGEN CHLORIDE-WATER
Total Pressure, 760 mm.

Constant Maximum Boiling Point Mixture, °C.	Pressure, mm.	Density at 25° C.	Weight Percent of Hydrochloric Acid
108.584	760	1.0959	20.222
107.859	740	1.0962	20.268
106.424	700	1.0966	20.360
110.007	800	1.0955	20.155

Constant maximum boiling-point mixtures are also known of the systems: **hydrobromic acid**-water, **hydriodic acid-water**, **hydrofluoric acid-water**, **nitric acid-water**, **sulfuric acid-water**, **formic acid-water**, **acetone-chloroform**, etc.

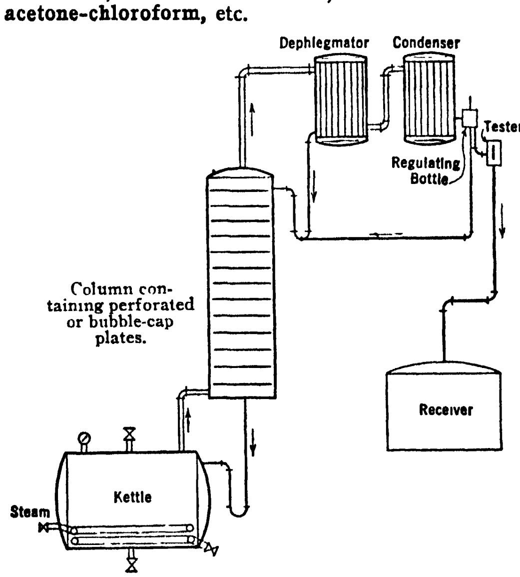

Fig. 4. Intermittent still used in the distillation and separation of liquid mixtures.

Plain Distillation is conducted in an apparatus consisting of three essential parts connected in series, namely, (1) the still or retort, (2) the condenser, (3) the receiver. The material is heated in the still or retort, its vapor passes into the condenser in which the vapor is cooled, and the liquid condensate is collected in the receiver. Modifications of this set-up are introduced affecting (1) the pressure in the apparatus and (2) the degree of refluxing to which the vapor is subjected.

The system may be closed to the atmosphere and the pressure within increased or diminished as desired, resulting in pressure or vacuum distillation respectively.

The system may be subjected to refluxing by the introduction of a fractionating column between the still and condenser. The column may contain (1) any of various styles of packing material such as coke fragments, or Raschig rings, or (2) a series of horizontal plates that are either (a) perforated or (b) have bubble caps, through which the vapor ascends. The plates also have overflow tubes for the liquid to descend from plate to plate. The desideratum is always the intimate mixing of ascending vapor and descending liquid throughout the whole column. Assuming that the rate of flow is constant, the upward rate of flow of the vapor, V, in mols per sec., minus the downward rate of flow of liquid, L, in mols per sec., equals the condensed output, C, from the top of the column, in mols per sec., and $\frac{L}{V}$ is called the reflux ratio. Fractional distillation is practiced on a large scale in the production of **alcohols, benzene hydrocarbons,** and **petroleum** fractions.

When a substance such as **aniline** has a high boiling point but an appreciable vapor pressure at 100° C. and is practically insoluble in water, use is frequently made of steam to distil the substance. The total or atmos-

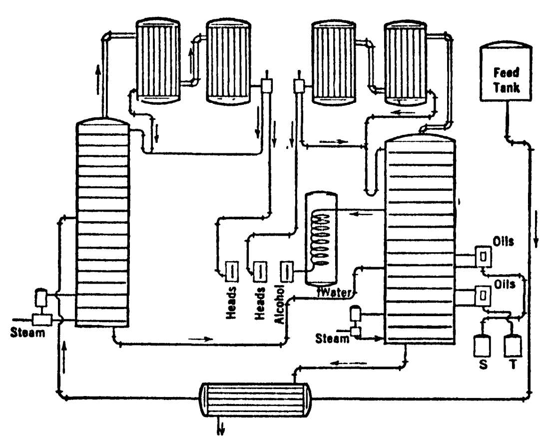

Fig. 5. Continuous still used in the distillation and separation of liquid mixtures.

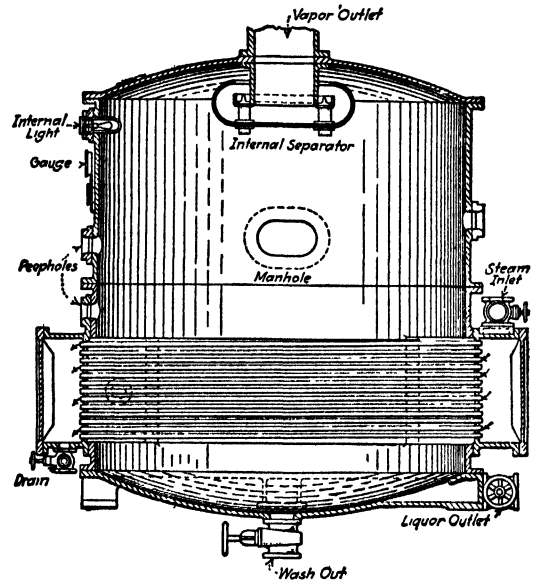
pheric pressure equals the sum of the partial pressure of the substance, somewhat below 100° C., and of the partial pressure of water vapor at that temperature. The distillate contains the substance and water approximately in the weight ratio: the product of the vapor pressure of the substance and its molecular weight *to* the product of the vapor pressure of water (733 mm. at 99° C., 707 mm. at 98° C.) and 18 (the molecular weight of water).

Evaporation is in principle the same operation as plain distillation, with the modifications in practice that (1) the vapor may or may not be recovered, (2) the residue in the evaporator may or may not contain solids, and (3) vacuum evaporation is frequently used in a single compartment or in multiple stages with each successive stage operated at an increasing vacuum utilizing the heat of condensation of the vapor from the preceding stage. In multiple stage evaporators there is a saving in the cost of heat and an increased expenditure for apparatus. Vacuum evaporation is frequently utilized to lower the temperature to which a substance is subjected and thus avoid decomposition by passing a current of warm dry air over the substance. Combined high-vacuum and very low temperature evaporation or drying is practiced in the final removal of water vapor from frozen penicillin, due to the heat-sensitive nature of this material. Water vapor passes from the place of higher concentration, that is, the substance, to the place of lower concentration, that is, the air, and is thus removed from the substance. If oxygen of the air reacts with the substance, an inert gas such as nitrogen may be substituted for air.



Zaremba horizontal tube evaporator.

Drying may be carried out in two different ways, either *batch* or *continuous.* In batch drying, the drier is filled with wet material and run until the material is dry, when the material is removed and the process is repeated. In continuous drying, the material is moved slowly through a tunnel. The hot gas enters at one end and the wet stock enters at the other. By the time the material has passed through the tunnel it is dry. Many devices are used to move the stock through the tunnel, such as carts equipped with trays, or conveyor belts. Finely divided material can be moved forward through a drier by having the drier itself made in the form of a slowly rotating, slightly inclined hollow cylinder. Such a rotary drier has the advantage of turning over the material and rolling it along at the same time, thus keeping fresh surfaces continually exposed.

For any substance, the drying rate can be determined by the following equation:

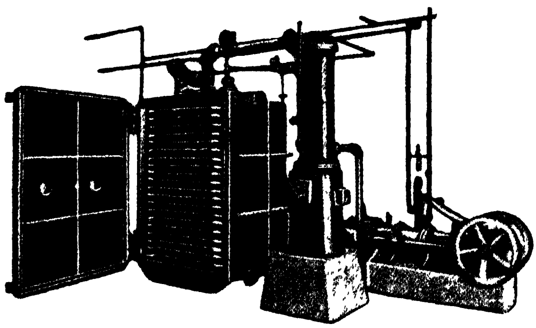
$$W = kA\Delta H,$$

where W = weight of water evaporated per unit time,
A = area available for drying,
H = humidity difference = humidity of air saturated with water minus humidity of air being used,
k = a constant characteristic of the material. k remains constant as long as the surface is completely wet but usually becomes smaller as the material approaches dryness.

The effect of air velocity, air **humidity,** temperature, and dimensions of the solid being dried have been studied in a quantitative manner for a number of materials, such as wood in the seasoning process, clay in ceramic goods, and leather. The higher the air velocity while the material is wet the more rapid the drying, but this effect diminishes as the material dries, due to the preponderance of the capillarity effect in transfer of water from the interior, through the interstices of the material to the air.

It is interesting to note that a great many materials ordinarily considered dry actually contain an appreciable amount of water. Dry glue, for example, becomes quite sticky on humid days but may become very brittle when

subjected to long periods of low humidity. The swelling and shrinking of wood with changes in the weather are other examples. The amount of moisture which a sub-



Vacuum shelf drier installation (open) with surface condenser (center) and dry vacuum pump (right).

stance will retain in this manner is called its *equilibrium moisture content,* and depends on the humidity of the air to which the material is exposed. (R.K.S., D.E.M.)

DISTORTION. Distortion is one of the major limiting factors in any communications system, being a measure of the failure of the system to reproduce exactly at the receiver the signal which was applied at the transmitter. The amount of this distortion which can be tolerated varies with the different types of communication, and both for electrical and for economic reasons a system is usually not made much better than necessary.

Distortion may be divided into three types: frequency distortion, which is caused by the system (or some part of it) not responding to all frequencies equally; amplitude distortion, which is caused by the system not responding to amplitude of signal linearly; and finally, phase distortion which is caused by different frequencies being shifted in phase by varying amounts. The first two are important in sound communication while all three are important in **television.** Frequency distortion is determined by the circuit's ability to respond to a wide frequency band. The average human ear will respond to a range of about 20 to 15,000 cycles, but all of this range is not necessary for most services so the systems are not designed to respond to such a wide range. For telephone service the range from about 250 to 2800 cycles gives ample articulation and is the usual band employed. A wider band is not necessary and would greatly increase the cost of apparatus and the difficulties from interference. Radio broadcast service requires a much wider band since it is designed for entertainment and must give a fair reproduction of the original music. Amplitude modulation systems are usually limited to an upper value of about 5000 cycles to keep the side bands within the allowed **channel** and to avoid excessive noise pick-up which a wider band would introduce. Frequency modulation, being inherently more noise-free, uses a much wider band, going to the upper limit of audibility. When any system fails to reproduce the applied frequency range linearly it gives frequency distortion, which may or may not be objectionable. Amplitude distortion usually results from some component saturating when a large signal is applied, frequently the distortion occurring for one polarity of the signal current or voltage and not the other. This has the effect of introducing new frequencies which are harmonics of the original ones. Phase distortion is not important for sound since the ear is not sensitive to it, but in picture work it produces very noticeable distortion in the reproduced picture. It is caused by circuit elements offering different **impedances** at different frequencies and is one of the most difficult forms to eliminate when the frequency range of the system is very wide. Often compensating networks are introduced in the line-up of a system to counterbalance certain distortions and give an over-all response free from distortion. (L.R.Q.)

DISTRIBUTED CAPACITANCE. The capacitance which is inherent in any coil because of the adjacent turns, layers, windings, etc., which are separated by some dielectric material and which have voltage differences between them. The result of this is a capacitance action which lowers the effective **inductance** of the coil. This capacitance is often considered as lumped and in parallel with the true inductance of the coil. (L.R.Q.)

DISTRIBUTED LOAD. Load.

DISTRIBUTION. The portions of the earth's surface occupied by different kinds of animals are determined by the relation of environmental conditions and inherited adaptations and result in a spatial arrangement of living forms known as distribution.

In vertical or altitudinal distribution animals may be surrounded either by water or by air, and may either rest on the solid surface, float in the surrounding medium, or move actively through this medium. Those which rest on the solid support constitute the faunal group known as the benthos, those which float are the plankton, and those which move actively through air or water are the nekton. Since animals can float permanently in water but not in air, and since the aerial nekton are commonly known as flying animals, these terms are largely restricted to aquatic species.

Horizontal distribution relates the animals to geographic divisions. The earth has been divided into a number of zoogeographical regions characterized by some uniformity of the included species. These are as follows: The palaearctic region includes Europe, Iceland, Northern Africa and Arabia, and Asia north of the Himalayan mountains. The nearctic region includes North America, Greenland, and part of Mexico. The neotropical region includes most of Mexico, the West Indies, and South America. The Ethiopian region includes Africa and Arabia south of 20° N. Lat., and sometimes Madagascar, although this island is also held to be a distinct region. The Oriental region includes India and China south of the Himalayas, the Malay Peninsula, Celebes, Java, Ceylon, Sumatra, and smaller adjoining islands. The Australian region includes Australia, New Guinea, New Zealand, and the remaining Pacific islands with the exception of the Hawaiian group, which constitute a small separate region. (See also **Gaussian Distribution.**) (A.W.L.)

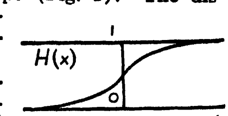
DISTRIBUTION FUNCTION. Given the **probability function of a discrete variate,** P_x, $a \leq x \leq b$, the distribution function $H(x)$ is defined as

$$H(x) = \sum_{x=a}^{x=x} P_x.$$

Always $H(a) = 0$, $H(b) = 1$. Given the probability function of a **continuous variate** $P_x dx$, $a \leq x \leq b$, the distribution function $H(x)$ is defined as

$$H(x) = \int_{x=a}^{x=x} P_x dx.$$

In this case also $H(a) = 0$, $H(b) = 1$. The distribution function generally has an S shape (Fig. 1). The distribution function is the mathematical counterpart of the **cumulative frequency distribution.**



The distribution function is important since it gives the probability of x being less than or equal to a particular value x_0. (L.A.A.)

DISTRIBUTIVE LAW OF ALGEBRA. Multiplication.

DISTRIBUTOR. This is a rotary electrical switch used to distribute electric current from one source to a number of separate circuits. A common example is the distributor of the automobile engine **ignition system.** High-tension ignition current suitable for use by spark plugs is delivered to the distributor at its revolving switch arm. Around the periphery of the travel of this distributor arm are mounted contact points which are connected to the various circuits to which the current is to be distributed. On the multi-cylinder gasoline engine, each circuit leads to a separate spark plug, and there are as many contact points as there are spark plugs. The rotation of the distributor arm brings it successively opposite the contact points. There may be actual contact between the distributor arm and the contact points, or the current may be required to jump a small gap between them. Its voltage must be high enough to do this. The contact points are mounted in a case of insulating material such as bakelite. The distributor arm is mounted on a rotating shaft driven from the crankshaft. In the four-cycle engine this shaft revolves at one-half crankshaft speed. It revolves at crankshaft speed in the two-cycle engine. (F.T.M., L.R.Q.)

DISTURBANCE. Used by structural geologists to designate an **orogenic** deformation of less area and intensity than a **revolution.** (R.M.F.)

DITHIONIC ACID AND DITHIONATES. Dithionic acid ("hyposulfuric acid" $H_2S_2O_6$) is a colorless solution, formed by reaction of **barium** dithionate solution and dilute **sulfuric acid,** and filtering off barium sulfate. The resulting solution may be evaporated in vacuum to specific gravity 1.35 beyond which point decomposition occurs, with resulting formation of sulfuric acid and **sulfur dioxide.** Dithionic acid does not react in the cold with **chlorine, sulfur, nitric acid, permanganate** or **hypochlorite,** but **sodium** peroxide oxidizes it to **sulfate.**

Sodium dithionate ($Na_2S_2O_6$) is made by reaction (1) of barium dithionate and sodium sulfate, and filtering off barium sulfate, (2) of dithionic acid and sodium hydroxide, (3) of **sodium** sulfite solution and **iodine,** some sulfate being formed.

When **sulfurous acid** is allowed to come in contact with suspensions of **manganese** dioxide, **ferric** hydroxide, **cobaltic** hydroxide, but not barium peroxide, or sodium sulfite and lead dioxide, in the cold, the corresponding dithionate is formed, and this may be conveniently converted into barium dithionate by reaction with barium hydroxide, and filtering. The solution of barium dithionate is then evaporated to **crystallization.** (R.K.S.)

DIURETIC. Any **drug** or substance which increases the urine volume. Water is the most common diuretic. In medicine, mercury compounds are frequently used to produce diuresis in **edema** and **ascites** due to heart disease. (D.M.H.)

DIURNAL CHANGES. In the course of a normal 24-hour period, atmospheric features change in a cyclic manner, returning to the approximate value again at the end of each 24-hour period. Some types of clouds and weather reach a maximum or a minimum during certain parts of a day. Daily changes are known as diurnal changes.

1. Surface pressure undergoes two definite periods of increase and two of decrease. Mean maximum pressure occurs approximately at ten o'clock local time in the morning and evening, and mean minimum pressure occurs at four in the afternoon and morning. In the tropics, this surge and ebb of pressure are very pronounced and highly rhythmic.

2. Temperature tends to become a maximum about 2–3 hours after local noon and a minimum at sunrise. Over water there is a minimum diurnal change as small as a fraction of a degree and over sandy and rocky desert a maximum which sometimes amounts to 100° or more.

3. Relative humidity tends to become a maximum about sunrise and a minimum in the afternoon.

4. Over land, cumulus-type clouds tend to be a maximum during afternoons and a minimum at night.

5. Fogs tend to be a maximum at and shortly after sunrise and minimum in the afternoon.

6. Rough flying air tends to be a maximum in mid-afternoon and a minimum at night.

Diurnal changes are primarily associated with the apparent movements of the sun. (P.E.K.)

DIVER. Aves, Gaviiformes. Large diving birds (**Aves**) with strong pointed beaks and webbed feet, found throughout the northern part of the world. The **loons.** The most common species is the great northern diver. (A.W.L.)

DIVERGENCE. **Convergence and Divergence.**

DIVERGENCE OF A VECTOR FUNCTION. The divergence of a vector function is a certain type form of mathematical expression which occurs very frequently in discussions of mathematical physics.

Let $\mathbf{v}$ be a **vector function** of position, with rectangular components v_1, v_2, and v_3 (in magnitude). The **scalar** expression

$$\nabla\cdot\mathbf{v} = \frac{\partial v_1}{\partial x} + \frac{\partial v_2}{\partial y} + \frac{\partial v_3}{\partial z}$$

is called the divergence of $\mathbf{v}$, and is denoted by div $\mathbf{v}$.

A fundamental property of the divergence is the so-called **divergence theorem.**

If $\mathbf{r}$ is a variable vector of the form $\mathbf{r} = x\hat{i} + y\hat{j} + z\hat{k}$, and if $\boldsymbol{\alpha}$ is a constant vector, then

$$\operatorname{div}\mathbf{r} = \nabla\cdot\mathbf{r} = 3,$$

$$\operatorname{div}(\mathbf{r}\times\boldsymbol{\alpha}) = \nabla\cdot(\mathbf{r}\times\boldsymbol{\alpha}) = 0,$$

$$\operatorname{div}(r\boldsymbol{\alpha}) = \nabla\cdot(r\boldsymbol{\alpha}) = \frac{\mathbf{r}\cdot\boldsymbol{\alpha}}{r}.$$

If $\mathbf{u}$ and $\mathbf{v}$ are vector functions of position and u is a scalar function of position, then

$$\operatorname{div}(\mathbf{u}+\mathbf{v}) = \nabla\cdot(\mathbf{u}+\mathbf{v}) = \nabla\cdot\mathbf{u} + \nabla\cdot\mathbf{v} = \operatorname{div}\mathbf{u} + \operatorname{div}\mathbf{v},$$

$$\operatorname{div}(u\mathbf{v}) = \nabla\cdot(u\mathbf{v}) = (\nabla u)\cdot\mathbf{v} + u(\nabla\cdot\mathbf{v}),$$

$$\operatorname{div}(\mathbf{u}\times\mathbf{v}) = \nabla\cdot(\mathbf{u}\times\mathbf{v}) = \mathbf{v}\cdot(\nabla\times\mathbf{u}) - \mathbf{u}\cdot(\nabla\times\mathbf{v}),$$

$$\operatorname{div}(\operatorname{grad} u) = \nabla\cdot(\nabla u) = \nabla^2 u \quad \text{(Laplacian of } u\text{)}.$$

An alternative definition of the divergence is the following:

Let $\mathbf{v}$ be a vector function of position, let δ be a small region of space and also its volume, surrounding a point P, and let ω be the bounding closed surface of δ and let $d\sigma$ be a surface element on ω; let $\mathbf{n}$ be an outward drawn normal unit vector to any point on ω. The outward flux through the element $d\sigma$ is $\mathbf{n}\cdot\mathbf{v}\,d\sigma$. The total flux outward through ω is the integral of this expression, and represents the net quantity of outward flow from δ per unit time. The limit approached by the quotient of net flow by the volume δ, as $\delta\to 0$, gives the rate of diminution of density. This is

$$\operatorname{div}\mathbf{v} = \nabla\cdot\mathbf{v} = \lim_{\delta\to 0}\frac{1}{\delta}\iint_{\omega}\mathbf{n}\cdot\mathbf{v}\,d\sigma.$$

(L.L.S.)

DIVERGENCE THEOREM. **Green's Theorem in Space.**

DIVERGENCY OF SERIES. **Infinite Series.**

DIVERSITY. That characteristic of public consumption of a good specifically produced and marketed for public use, known as diversity, arises from the diversification of use of the commodity by individual customers. In a public utility system marketing a commodity which may be stored, diversification is not of as much importance as in services such as transportation and electric power, where warehousing the salable commodity is either impossible or impractical. Thus, in a water or gas system, a certain amount of storage may be interposed between supply and demand which would effect the result that only a diversification of usage can achieve in the electric service system.

In the case of an electric utility system, the fact that customer A requires 5 kilowatts during some part of the day, customer B, 8, and C, 7 kilowatts, does not mean that at some time during the day 20 kilowatts will be drawn from the supply line. The diversity of usage between customers would so stagger their periods of maximum demand that the feeder capacity could be considerably less than the sum of the individual maximum demands. Taking into account a certain amount of diversity between feeders themselves, and between substations supplying these feeders, the maximum demanded load of a power plant is likely to be only a small fraction of the sum of the individual customer's peak loads. Diversity factor is the ratio between individual maximum demands of parts of a system and their combined simultaneous maximum demand. It is defined as the maximum simultaneous demand of a system or part of a system, divided by the sum of the individual maximum demands of the subdivision, taken as they may occur. A low diversity factor is a desirable loading condition. (F.T.M., L.R.Q.)

DIVERSITY FACTOR. **Diversity; Group Drive.**

DIVERSITY RECEPTION. **Fading** has been found to vary from place to place at a given time. Thus if a radio signal is received simultaneously at points separated by a few wavelengths' distance it is found that the outputs of the receivers do not all fade together. Diversity reception is a method of utilizing this effect to minimize the fading. Basically such a system consists of 2 or more (3 is quite common) antennae separated by several wavelengths (at least 10 times the wavelength of the received wave is desirable and 3 antennae placed at the vertices of an equilateral triangle give the best positioning) feeding separate radio-frequency receiver channels. The outputs of these channels are then combined to give a single output. By means of automatic gain control circuits the antenna receiving a non-faded signal supplies most of the output and as the signals at the different antennae fade out and back in, the control system acts to maintain a constant output level. While such a system, because of its complexity, is not suitable for home reception, it is widely used for reception of foreign broadcasts for rebroadcasting in this country. It is also used for transoceanic telephone reception. (L.R.Q.)

DIVIDERS. **Measurement.**

DIVI-DIVI. **Tannins.**

DIVISION. Division is the **inverse operation** to **multiplication.** The result of dividing one number by another is called their quotient. The quotient a/b of two numbers a and b is that number c such that $b \cdot c = a$ (provided $b \neq 0$). It follows that $(a/b) \cdot b = a$ and $(a \cdot b)/b = a$. That is, division undoes the effect of multiplication.

The reciprocal of a number a is the quotient of 1 by that number, namely $1/a$. The reciprocal of a **fraction** is that fraction inverted.

The quotient of two numbers of like sign is positive, that of two numbers of unlike sign is negative, the **absolute value** being the quotient of the absolute values of the numbers.

To find the quotient of two **polynomials,** arrange each in descending powers of some common letter involved. Divide the first term of the dividend by the first term of the divisor; the result is the first term of the quotient. Then multiply the whole divisor by the first term of the quotient and subtract the product from the dividend. Consider the remainder thus obtained as a new dividend and repeat the operation. Continue in this manner until a remainder is obtained which is either zero or an expression whose first term does not contain the first term of the divisor as a factor. (L.L.S.)

DOBSON FLY. **Corydalis.**

DOCTRINE OF SIGNATURES. This curious belief came into existence during the Middle Ages. According to its proponents, every plant was created for a purpose, and, more than that, was marked so that its purpose could be known. The most able interpreters of this doctrine were those gifted with an imagination capable of discovering the signature.

If the shape of the leaf suggested that of the human heart or liver, then obviously that plant, or its leaves, was meant to be used to cure diseases of the heart or the liver. A little plant, which has small white flowers with a conspicuous dark spot in the center, is known as Eyebright. It was quite clear that this plant was marked as a plant which should be used to treat eye trouble. Common walnuts were seen to resemble a skull—the meat within was very like the human brain in appearance. Surely here was a remedy for any trouble which originated in the brain. A certain **lichen,** *Usnea barbata,* commonly known as Old Man's Beard, grows on dead branches of trees, from which it hangs in slender branching threads. A decoction of this lichen was therefore used to promote growth of the hair.

Sometimes the marks or signs were extremely obscure. One lichen, for example, commonly grows on barren rock surfaces. This lichen, *Parmelia saxatilis,* will also grow on old bones, including skulls, if the latter happen to be in a favorable spot. Surely anything growing on a skull is valuable; so here is a plant which is a cure for epilepsy and also a healing salve for wounds. (R.M.W.)

DODO. Aves, Columbiformes. A large clumsy flightless bird, *Didus ineptus,* once common on the island of Mauritius but now extinct. (A.W.L.)

DOG. Mammalia, Carnivora. A member of certain species of the dog family (Canidae), characterized by the slender build, long legs, elongate muzzle, and blunt claws which cannot be retracted.

The family is represented in all continents but the wild species are known as dogs only in the case of a few which inhabit Asia, Africa, and South America, including the raccoon dog and the Siberian wild dog. The species that bear special names are the **wolves, coyote, kaberu, jackals, dingo, foxes** and **fennecs.**

The name is best known as applied to the domestic dog, *Canis familiaris,* one of the most highly diversified of animals as a result of long selection and controlled breeding. (A.W.L.)

DOG, LATHE. **Lathe.**

DOGFISH. Pisces. 1. Plagiostomi. Several species of small **sharks,** all marine. 2. Holostei. The **bowfin,** also called the fresh-water dogfish. (A.W.L.)

DOLDRUMS. **Circulation of the Atmosphere.**

DOLERITE. The term dolerite, derived from the Greek meaning deceitful, was originally applied to all dark, heavy, fine-grained **igneous rocks** of doubtful character. It is now used to indicate gabbroid or basaltic types occurring as dikes or sills whose mineralogical composition is **plagioclase, feldspar, hornblende** or **pyroxene** or both, **olivine** and perhaps **biotite, magnetite** or **ilmenite** and **pyrite.** Included in the dolerites are the diabases, which display plagioclase laths in a somewhat radial arrangement, and from this circumstance we have the textural term diabasic which is synonymous with ophitic.

Both terms dolerite and diabase have been used interchangeably but the suggestion of Kemp that diabasic refers to rocks in which the feldspar is in excess and the augite occupies the interstices between the feldspar laths is one which should receive more attention. (E.S.C.S.)

DOLICHOCEPHALIC VS. BRACHIOCEPHALIC. Paleontology of Man.

DOLOMITE. The mineral dolomite, the **carbonate** of **calcium** and **magnesium,** corresponds to the formula $CaMg(CO_3)_2$ and closely resembles **calcite.** Its crystals, **rhombohedral** in habit, fall in the **hexagonal** system. Like calcite it may be massive or granular, some marbles being dolomite rather than calcite. It displays a perfect cleavage parallel to the rhombohedron; sub-conchoidal fracture, brittle; hardness, 3.5–4; specific gravity, 2.8–2.9; luster vitreous to pearly; color varies widely, white, reds, greens, black, browns, yellows or colorless; transparent to translucent. Unlike calcite, dolomite dissolves very slowly if at all in dilute cold hydrochloric acid; powdered dolomite will dissolve in warm acid. This is the common test for the two minerals. Much dolomite occurs as stratified rocks where it is believed to have been formed by a secondary process, probably by the action of waters charged with magnesium compounds. Dolomite also is found as a vein mineral, as is calcite. **Iron** or **manganese,** rarely zinc or **cobalt,** may replace some of the magnesium. **Ankerite** is the name given to a mineral whose composition is essentially a calcium-magnesium-iron carbonate. Among the many noted localities for dolomite may be mentioned the following: Saxony, Switzerland, Italy, France, Spain, Brazil, Mexico and in the United States at Roxbury, Vermont; Lockport, New York; Phoenixville, Pennsylvania; Alexander County, North Carolina; Hancock County, Illinois, and the Joplin District, Missouri. It was named for Deodat de Dolomieu who first described its characteristics. (E.S.C.S.)

DOLOMITIC LIMESTONE or DOLOMITE. Many of the **carbonate** rocks consist largely of the mineral dolomite, the double carbonate of **calcium** and **magnesium,** thus differing from ordinary **limestone** which is essentially carbonate of calcium. Such rocks are called dolomites. It should be noted, however, that the term dolomite is sometimes loosely used to mean a magnesian limestone. The term dolomite is properly restricted to the rock made up of the double carbonate, $CaMg(CO_3)_2$. Dolomite occurs in bedded deposits probably as a chemical precipitate either as the result of inorganic or organic agencies, or in certain cases because of leaching-out of the calcium with the accompanying concentration of the magnesium, or from the carbonates of decomposed shells of marine animals. The replacement of calcium carbonate by dolomite is also of importance. Dolomite is used to some extent as a building stone, as a refractory and in the production of heat insulating materials. (E.S.C.S.)

DOLPHIN. 1. Pisces, Teleostei. Marine game fishes (Pisces), ***Coryphaena,*** **with a deep head, short snout, and long tapering body. They look like the mammalian dolphins in general form. 2. Mammalia, Odontoceti.** Small toothed **whales,** attaining a length of about eight feet. There are many species of several characteristic forms. One of the more peculiar is the narwhal, *Monodon monoceros,* which has a single spirally twisted ivory tusk. Several species of dolphins live in large rivers of the Old and New World tropics, among them the Gangetic dolphin or susu of India and the Amazonian dolphin, *Inia geoffroyensis,* also called the inia or bouto, of South America. (A.W.L.)

DOME. As used by the geologists this term has several meanings. Principally applied to mounds of viscous lava which are squeezed out of volcanoes and solidify without forming lava flows. When portions of the older lavas or ashes are pushed up by the pressure of later lavas the resulting structure is called a volcanic dome. (R.M.F.)

DOMESTIC CHEMISTRY. Chemistry.

DOMESTIC HEATING. Heating.

DOMITE. The term proposed by Von Buch for the **trachyte** lavas of the famous volcanic Puy de Dôme district of France. More specifically, trachytes which contain appreciable amounts of **oligoclase** and **hematite.** (R.M.F.)

DOOLITTLE METHOD OF SOLVING NORMAL EQUATIONS. We shall show how the normal equations (1) may be solved readily by the Doolittle technique as simplified by P. Dwyer.

$$
(1)\qquad
\begin{aligned}
a_{11}w_1 + a_{21}w_2 + a_{31}w_3 &= a_{41}\\
a_{12}w_1 + a_{22}w_2 + a_{32}w_3 &= a_{42}\\
a_{13}w_1 + a_{23}w_2 + a_{33}w_3 &= a_{43}
\end{aligned}
$$

where $a_{ij} = a_{ji}$. The solution is given in tabular form with a check column and an explanation at the right hand side.

	w_1	w_2	w_3		Check	Explanation
	a_{11}	a_{21}	a_{31}	a_{41}	a_{51}	$a_{5i} = a_{4i} + a_{3i} + a_{2i} + a_{1i}$,
		a_{22}	a_{32}	a_{42}	a_{52}	remembering $a_{ij} = a_{ji}$
			a_{33}	a_{43}	a_{53}	
	a_{11}	a_{21}	a_{31}	a_{41}	a_{51}	$b_{i1} = \frac{a_{i1}}{a_{11}}$
	1	b_{21}	b_{31}	b_{41}	b_{51}	$b_{51} = 1 + b_{21} + b_{31} + b_{41}$
(2)		$a_{22.1}$	$a_{32.1}$	$a_{42.1}$	$a_{52.1}$	$a_{i2.1} = a_{i2} - a_{i1}b_{21}$
		1	$b_{32.1}$	$b_{42.1}$	$b_{52.1}$	$b_{i2.1} = \frac{a_{i2.1}}{a_{22.1}}$
						Check = sum of all items in row
			$a_{33.12}$	$a_{43.12}$	$a_{53.12}$	$a_{i3.12} = a_{i3} - a_{i1}b_{31} - a_{i2.1}b_{32.1}$
			1	$b_{43.12}$	$b_{53.12}$	$b_{i3.12} = \frac{a_{i3.12}}{a_{33.12}}$
						Check = sum of all items in row
	w_1	w_2	$b_{43.12}$			

In the last row $w_3 = b_{43.12}$, $w_2 = b_{42.1} - b_{32.1}w_3$, $w_1 = b_{41} - b_{31}w_3 - b_{21}w_2$. Finally the values of w_1, w_2, w_3 are checked in (1). While we have illustrated the method for three equations, $a_{ij} = a_{ji}$, the method is perfectly general for n equations, $a_{ij} = a_{ji}$.

We demonstrate how $r^2_{4.123}$ may be found, assuming the predictive equation, the **regression** of t_4 on t_1, t_2, and t_3, is given in **standard units**

$$t_i = \frac{x_i - \overline{X}_i}{\sigma_i}$$

$$t_4 = \beta_{41.23}t_1 + \beta_{42.13}t_2 + \beta_{43.12}t_3.$$

We must evaluate $\beta_{41.23}$, $\beta_{42.13}$, $\beta_{43.12}$. The normal equations are

$$\begin{aligned}(3)\qquad &\beta_{41.23} + \beta_{42.13}r_{12} + \beta_{43.12}r_{13} = r_{14}\\ &\beta_{41.23}r_{12} + \beta_{42.13} + \beta_{43.12}r_{23} = r_{24}\\ &\beta_{41.23}r_{13} + \beta_{42.13}r_{23} + \beta_{43.12} = r_{34}\end{aligned}$$

Here r_{ij} is the **coefficient of correlation** between x_i and x_j. This set of equations (3) corresponds to (1) with $\beta_{43.12} = w_1$, $\beta_{42.13} = w_2$, $\beta_{43.12} = w_3$, $r_{ij} = a_{ij}$, and $r_{ii} = a_{ii} = 1$. After we have found w_1, w_2, w_3, $r_{4.123}$ is given by

$$r_{4\,123} = \sqrt{a_{41}b_{41} + a_{42.1}b_{42.1} + a_{43.12}b_{43.12}}.$$

Thus both the regression equation for t_4 and $r_{4\,123}$ are determined simultaneously. Let $\sigma_{e4\,123}$ represent the **standard error of estimate** of x_4 based on the regression of t_4, then $\sigma_{e4.123} = \sigma_4\sqrt{1 - r_{4\,123}^2}$, $\sigma_4 =$ the **standard deviation** of x_4. The regression of x_4 on x_1, x_2, and x_3 will be

$$x_4 = B_{41}x_1 + B_{42}x_2 + B_{43}x_3 + B_4$$

$$B_{41} = \beta_{41\,23}\frac{\sigma_4}{\sigma_1},\quad B_{42} = \beta_{42.13}\frac{\sigma_4}{\sigma_2},\quad B_{43} = \beta_{43\,12}\frac{\sigma_4}{\sigma_3}$$

$$B_4 = \sigma_4\left(\frac{\bar{X}_4}{\sigma_4} - \frac{\bar{X}_1}{\sigma_1} - \frac{\bar{X}_2}{\sigma_2} - \frac{\bar{X}_3}{\sigma_3}\right)$$

$\bar{X}_i =$ the **mean** of x_i.

To find $r_{43\,12}$, the **coefficient of partial correlation** between x_4 and x_3 when x_1 and x_2 are kept constant, we have

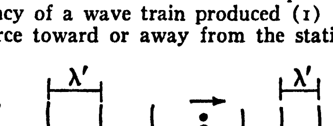
$$r_{43.12} = \sqrt{\beta_{34.12}\beta_{43.12}}.$$

We have shown how $\beta_{43\,12}$ is obtained and $\beta_{34\,12}$ is found similarly by solving another set of three equations in three unknowns. In exactly the same way $r_{41\,23}$, $r_{23\,14}$, and $r_{42\,13}$ are found.

The methods have been illustrated for four variables but are perfectly general. (L.A.A.)

DOOR-KNOB TUBES. These are vacuum **tubes** especially built for **ultra high frequency** use where the lead inductance and the capacitance between electrodes of the conventional tubes prevent their use. The door-knob tube gets its name from its resemblance to a door knob, the peculiar shape being the result of an effort to get the leads as short as possible and have a minimum amount of dielectric material in the construction. These tubes do not have a conventional base, the leads being brought out directly through the glass and made heavy enough to serve as connections. (L.R.Q.)

DOPPLER EFFECTS. The effects upon the apparent frequency of a wave train produced (1) by motion of the source toward or away from the stationary ob-



Doppler effect of motion of source. λ' is the altered wave length.

server, and (2) by motion of the observer toward or from the stationary source; the motion in each case being with reference to the (supposedly stationary) medium.

(1) It is easy to see that when the source moves, the waves are crowded together on the side toward which it moves, and are more widely separated on the opposite side, thus producing, respectively, an apparent increase and an apparent decrease in frequency. If the speed of the waves is V and that of the source is u, and if the true frequency is ν, the apparent frequency is

$$\nu' = \frac{V}{V+u}\nu; \qquad (1)$$

u being $+$ or $-$ according as the distance is increasing or decreasing. Thus if a whistle of actual frequency 250 per sec. is moving away from the listener with a speed of 11 ft. per sec., and the speed of sound is 1100 ft. per sec., the apparent pitch is lowered to $\frac{1100}{1111} \times 250$ per sec. $=$ 247.52 per sec. (This effect is often observed with the bell or the whistle of a passing locomotive.)

(2) If the observer is moving with speed u, which is $+$ or $-$ according as his distance from the stationary source is increasing or decreasing, the apparent frequency is given by

$$\nu'' = \frac{V-u}{V}\nu. \qquad (2)$$

Then if the listener moves away from the whistle at 11 ft. per sec., the pitch is lowered to $\frac{1089}{1100} \times 250$ per sec. $=$ 247.50 per sec. The two effects are thus very nearly but not quite equal; frequently both are operative at once.

The Doppler effects are of great importance in the case of light (for which it is quite impossible to distinguish between them). The slight abnormality (Doppler shift) in the positions of the spectrum lines from a star, for example, affords a fairly accurate value of the relative speed with which the star and the earth are approaching or receding from each other (the **radial velocity**). Many **double stars (spectroscopic binaries)** are recognized as such only by the doubling of their spectrum lines due to the components moving in opposite directions. The spectrum lines of gases are often broadened because of the various speeds of the molecules. (L.D.W.)

DORAB. Pisces, Teleostei. A slender marine fish **(Pisces)** of the Oriental region, of large size and vicious habits. (A.W.L.)

DORMOUSE. Mammalia, Rodentia. Small arboreal **rodents** of the Palaearctic and Ethiopian regions. They are somewhat like squirrels in appearance, with long hairy or bushy tails. Also called sleepers. The common dormouse is *Muscardinus avellanarius*. (A.W.L.)

DORSAL LAMINA. In the **tunicates,** a ciliated ridge along the middle line of the dorsal wall of the **pharynx.** (A.W.L.)

DORY, JOHN DORY. Pisces, Teleostei. Marine fishes **(Pisces)** of ugly form and world-wide distribution. The John dory, *Zeus faber*, is a species of the northern hemisphere which is valued as food. Family Cyttidae. (A.W.L.)

DOT PRODUCT OF TWO VECTORS. **Scalar Product of Two Vectors.**

DOTTEREL. Aves, Charadriiformes. *Eudromias.* Several Old World species of birds **(Aves)** related to the plovers. (A.W.L.)

DOUBLE-CURRENT GENERATOR. If a **synchronous converter** is driven mechanically both a.c. and d.c. may be taken from it, the first from the **slip ring** connections and the second from the **commutator** connections. (L.R.Q.)

DOUBLE INTEGRAL. A double integral is a fundamental mathematical concept extensively used in **Calculus** for the treatment of geometric and physical problems, particularly those dealing with plane figures.

Let $f(x, y)$ be a **continuous function** in a region S of the XY-plane. Let the region S be divided in any manner into n sub-regions ΔS_1, ΔS_2, $\cdots$, ΔS_n; denote any one of these sub-regions by ΔS_k and also denote its area by ΔS_k. Let (x_k, y_k) by any point within or on the boundary of ΔS_k. Then form the sum

$$\sum_{k=1}^{n} f(x_k, y_k)\cdot\Delta S_k = f(x_1, y_1)\Delta S_1 + \cdots + f(x_n, y_n)\Delta S_n.$$

Let $n \to \infty$ and at the same time let the greatest diameter of each sub-region $\Delta S_k \to 0$. Then the limit of this sum is defined as the double integral of $f(x, y)$ extended over the region S, and we write:

$$\lim_{\Delta S_k \to 0} \sum_{k=1}^{n} f(x_k, y_k)\Delta S_k = \iint_S f(x, y)dS.$$

A double integral may be interpreted geometrically as follows: If $z = f(x, y)$ is interpreted as the equation of a **surface**, the double integral $\iint_S f(x, y)dS$ represents the volume bounded by this surface, the XY-plane and a right **cylinder** standing on the boundary of the region S and perpendicular to the XY-plane.

Let $f(x, y)$ be continuous in a region S of the XY-plane bounded by the lines $x = a$, $y = b$, the X-axis and a curve $y = \phi(x)$, in **rectangular coordinates.** The integral

$$\int_a^b \left(\int_0^{\phi(x)} f(x, y)dy \right) dx,$$

which is called an iterated, or repeated, double **integral,** is defined as follows: hold x constant and integrate $f(x, y)$ with respect to y, substitute the limits $\phi(x)$ and 0 for y and subtract, then integrate this function of x with respect to x from a to b.

This iterated integral is sometimes written

$$\int_a^b \int_0^{\phi(x)} f(x, y)dydx, \quad \text{or} \quad \int_a^b dx \int_0^{\phi(x)} f(x, y)dy,$$

and occasionally as

$$\int_a^b \int_0^{\phi(x)} f(x, y)dxdy.$$

The fundamental theorem on double integrals is the following: Let S be a region bounded by the lines $x = a$, $x = b$, the X-axis, and a curve $y = \phi(x)$. Then the following double integral and iterated integral are equal:

$$\iint_S f(x, y)dS = \int_a^b \left(\int_0^{\phi(x)} f(x, y)dy \right) dx;$$

i e, the double integral may be evaluated by the iterated integral (using successive integrations).

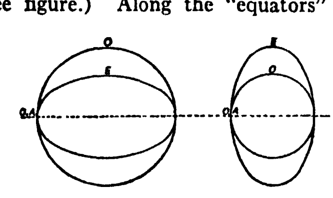
In terms of **polar coordinates,** a double integral $\iint_S f(r, \theta)dS$ may be evaluated by an iterated integral of the form

$$\int_\alpha^\beta \left(\int_{r_1(\theta)}^{r_2(\theta)} f(r, \theta)rdr \right) d\theta.$$

(L.L.S.)

DOUBLE REFRACTION. If a crystal of **calcite** (calcium carbonate, a common mineral) is held between the eye and a pinhole in a card, two bright dots are seen. If the crystal is rotated around the line of sight, one dot travels in a circle around the other, which remains fixed. Evidently there are two refracted rays; with the light normally incident on the natural crystal face, they make (within the crystal) an angle of about 6° 9′. The two refracted rays reveal a difference in **refractive index.** The one which remains fixed as the crystal revolves, called the ordinary ray, corresponds to a greater index than does the other, called the extraordinary ray. For sodium light the two indices of calcite are, respectively, 1.658 and 1.486. A simple test shows that the two rays consist of plane-**polarized light,** one vibrating at right angles to the other. By cutting the calcite into plates making various angles with the natural faces, a divergence as high as 6° 16′ may be obtained for normal incidence; but it is generally less. For one direction (and, for calcite, only one) there is no divergence at all; the light is then said to be traveling along the optic axis of the crystal. Quartz also exhibits double refraction (though with much less divergence); but in this case the extraordinary ray corresponds to the greater refractive index (ordinary, 1.544, extraordinary, 1.553, for sodium light).

These phenomena were explained by Huygens (1678) as due to the fact that the ordinary wave has a spherical wave front, traveling with the same speed in all directions, just as if the medium were isotropic; while the extraordinary wave has either a maximum or a minimum speed along the optic axis, so that its wave front is either an oblate (door-knob-shaped) or a prolate (football-shaped) spheroid, externally or internally tangent to the spherical ordinary wave front at the two points on the axis. (See figure.) Along the "equators" of the two



wave fronts the difference in speed is greatest. Here the extraordinary vibration is parallel to the axis, the ordinary vibration perpendicular to the axis; and the two vibration components, proceeding together, experience a progressively greater difference of phase. A "quarter-wave plate" is a layer cut just thick enough for this phase difference to be ¼ of a cycle.

Many crystals have two optic axes. In this case the double wave surface is a much more complicated system in which there are four points of intersection, corresponding to the two axes. Its section in the X-Z plane is a circle inside an ellipse and not touching it; in the Y-Z plane, an ellipse within a circle; and in the X-Y plane, which contains the axes, an ellipse intersecting a circle at four points. Crystals of **mica,** borax, and **topaz** are biaxial. (See also **Electric and Magnetic Double Refraction,** and **Photoelasticity.**) (L.D.W.)

DOUBLE SHEAR. Rivet; Shear.

DOUBLE STAR. (See **Binary** star.) There are numerous cases where two stars are so nearly in the same direction, as seen from the earth, that they appear as single stars to the unaided eye but may be separated into two components by the use of a telescope. Such a pair of stars is referred to as a double star. Double stars may be either one of two kinds. In cases where the two stars are only apparently close to each other (i e., lie in approximately the same direction from the earth, but are separated by a great distance in the radial direction) the pair is known as an optical double. In the great majority of cases, however, the stars are actually close enough together to exert strong **gravitational** attractions on each other and are in **orbital** motion relative to each other. Such physically connected stars form what is known as a **binary star.** Optical doubles may be distinguished from binaries by observing the pair in a telescope over a period of years. In case the distance between them changes progressively over a long period of time while the position angle (see **Filar Micrometer**) remains constant it may be safely assumed that the motion is due to **proper motion** alone and that an optical double is under observation. Position angle changes progressively and distance oscillates between a maximum and minimum in the case of a binary.

The first recorded discovery of a double star was by Riccioli in 1650 when Zeta Ursae Majoris was announced to be a double star. Since that time the search for

double stars has been carried on very thoroughly and every star, down to the 10th **magnitude**, has been carefully examined. Dr. R. G. Aitken, who has completed one of the most comprehensive surveys of variable stars thus far attempted, makes the following statement: "At least 1 in every 18, on the average, of the stars in the northern half of the sky which are as bright as 9.0 magnitude is a close double star visible with the 36-in. refractor." (W.K.G.)

DOUC. **Langur.**

DOUGLAS FIR. **Conifers.**

DOUROUCOLI. **Monkey.**

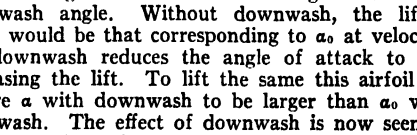
DOVE. **Pigeon.**

DOVEKIE. Aves, Charadriiformes. The black guillemot, *Uria grylla,* a marine bird (**Aves**) of the north Atlantic. Sometimes incorrectly applied to the little auk. Also spelled dovekee and dovekey. (A.W.L.)

DOVETAIL. An interlocking joint used in joinery and cabinet-making. (See **Bearings.**) (H.C.H.)

DOWEL. In woodworking, a wooden cylindrical pin for fastening two or more parts. In machine work, a cylindrical or tapered pin for locating and aligning parts. Dowels are sometimes used as transverse keys or driving pins where small torques are transmitted. (H.C.H.)

DOWNWASH. From an airfoil of finite span in flight there are a multitude of vortices trailing, forming a **vortex sheet.** As a result of circulatory flow about each vortex filament a net downwash flow of air is produced, having an important effect upon the air reactions. If the airfoil is untwisted, and elliptical in planform (or tapered in approximation of an ellipse), the vortices bound to the airfoil will produce a circulation of approximately elliptical strength distribution over the span. This produces a uniform downwash of air in the region of the wing. The combined effect of the forward motion of the airfoil and the downwash will be better understood upon reference to the accompanying diagram.



Downwash

The forward speed V_0 and the vortex-induced downwash w produce a resultant air velocity of V_r (substantially equal to V_0 in magnitude) which meets the airfoil at angle of attack α. The angle ϵ is called the downwash angle. Without downwash, the lift produced would be that corresponding to α_0 at velocity V_0, but downwash reduces the angle of attack to α thus decreasing the lift. To lift the same this airfoil would require α with downwash to be larger than α_0 without downwash. The effect of downwash is now seen to be deleterious since, for the same V and lift, it increases the needed α and produces extra drag. Furthermore this drag (**induced drag**) is not associated with aerodynamic cleanliness but with **aspect ratio.** Disposing the area of the wing as a slender wing of large wing span (i.e., high aspect ratio) is the way to reduce this form of drag. (F.T.M.)

DOWNWASH VELOCITY. **Downwash.**

DRAFT. Draft of a ship or boat is its depth of flotation. It is also the minimum depth of water in which navigation is possible.

In making a **pattern** which is to be molded in sand, a certain small taper is necessary where the pattern is of such shape as to be rather deeply imbedded in the sand. When the pattern is rapped or jarred loose from the sand, a slight taper, called, in foundry practice, draft, allows the pattern to pull free during its removal from the mold, without disturbing the side walls.

As applied to a gaseous system, *draft* is a pressure-differential that operates to move the gases. **Combustion** requires oxygen—and therefore air. To move this air through the fuel bed and to produce a flow of the gaseous products of combustion out of the furnace, then through the boiler, economizer, etc., requires a difference of pressure equal to that necessary to accelerate the gases to their final velocity, plus friction head losses. This difference of pressure is called draft whether measured above or below atmospheric pressure. The range of pressures required is most easily measured by manometers reading in inches of water.

A manometer measures pressures in terms of a displaced column of water. The pressure may be obtained from the manometer reading by employing the factor relating a head of water to the pressure produced at its base. It requires 2.31 ft. of water to result in a pressure of 1 lb. per sq. in. The ordinary draft gauge is a variation of the U-tube manometer.

Requisite draft can be obtained by use of **chimneys, fans,** steam or air **jets,** or combinations of these. The chimney is probably the most common, but the least understood of any of them. At one time the chimney was universally used as the sole means for producing a draft and even now it is relied on entirely in many small plants and partially in most of the large ones.

Mechanical draft may be classified as *forced* or *induced,* the former having the combustion air placed under a **plenum,** the latter referring to gas movement into a region of partial **vacuum.** With forced draft alone, furnace gases seep outward through cracks in walls, and blow through opened doors and ports. Induced draft alone allows considerable undesirable dilution of the products of combustion unless furnace, casings, ducts, etc., are maintained airtight. A logical compromise is to use both systems in a *balanced draft* adjusted to maintain atmospheric pressure (or a slight vacuum) in the furnace. There, expansion cracks, opened doors, etc., will not cause undesirable gas or air flows. (See **Foundry Practice; Watershed.**) (F.T.M.)

DRAFT GAUGE. As draft is always an extremely small pressure, special gauges have been devised for its measurement. An ordinary U-tube manometer is unsatisfactory for moderate draft since the liquid displacements are small. Inclined leg manometers (see **Manometer**) magnify the reading and place it on a single scale but need to be carefully levelled; also, the liquid is subject to evaporation, thus affecting the accuracy. Dry type draft gauges have been developed which operate from a spring-loaded diaphragm to one side of which is piped the pressure to be measured. Since a water-loaded U-tube manometer is a primary standard of reference, draft gauges are customarily calibrated to read "inches of water" no matter what their operating principle or fluid may be. (F.T.M.)

DRAFT TUBE. **Hydraulic turbines** frequently discharge the water with considerably more velocity than would be economical from the efficiency viewpoint, were it not possible to recover a great deal of that energy by the proper use of a diffusing chamber at the outlet. The diffusing chamber or tube is known as the draft tube, and there are a variety of types. However, the main objective is to convert the velocity head residing in the water leaving the turbine into pressure head. If this can be done efficiently, the turbine can be set somewhat below normal tailwater level.

The greater the **specific speed** of a turbine runner the higher will be the velocity of the water discharged into the draft tube, and the more important the recovery of this velocity by draft tube design. The draft tube is to take the water from the turbine at a point where the pressure is considerably less than atmospheric, and, by efficiently reducing the velocity, convert it into pressure head so that it can emerge smoothly into the tailrace at atmospheric pressure. By "efficiently" is meant without shock or whirl loss. Not all the velocity head can be recovered, for the water must be given to the tailrace at normal tailrace velocity to prevent its backing up into the turbine. Also, whatever friction loss occurs in the draft tube adds to this reduction of useful head. (F.T.M.)

DRAG, AERODYNAMIC. (See **Aerodynamics, Airfoil, Boundary Layer.**) An object subjected to an air stream is acted on by a resultant air pressure. Drag is the component of air reaction which is parallel to the air stream. Its origin is profile impact of molecules of air against the face of the object, the skin friction of the molecules of air as they slide along the object, the vortices and eddying air currents set up in an otherwise undisturbed air stream by the presence of the object, and the induction effects of **downwash,** if any. Drag is that quantity which imposes limitations upon the top speed of vehicles, missiles, and so forth. As it is proportional to the square of the velocity, its magnitude mounts rapidly as velocities are increased.

There are two kinds of drag—drag on surfaces which obtain a useful reaction from the air stream as well as a drag, and drag upon surfaces where the only reaction is the drag. A wing has both drag and lift. Drag on the wing is the price paid for lift, and is so accepted. A strut, or wire, or wheel, creates no lift, and the drag is wholly undesirable. A drag of this type is called **parasite drag.** Careful streamlining and reduction of parts exposed to the air stream are ways of reducing parasite drag. The drag of a wing may be divided into profile drag and induced drag. **Induced drag** depends upon the lift and the **aspect ratio** of a wing. During a test, profile and induced drag are not separable. Parasite drag depends upon the surface roughness and shape of the object.

Profile drag of airfoils is the result of skin friction and turbulent wake. It is greatly influenced by **Reynolds number** (scale effect) and by initial turbulence in the air stream. Although some authors have proceeded on the basis that this is the sole influence on profile drag coefficient, others have found that the profile drag coefficient has a small variation with coefficient of lift. However, the generally accepted theories of origin of aerodynamic forces imply that scale effects modify profile and parasitic drags only and are absent in lift and induced drag. Experience confirms the validity of theory except near the **burble** attitude where viscosity has an effect on lift.

Experiments in the **wind tunnel** show that factors affecting reaction of air on airfoils are:

1. The relative velocity of the air and airfoil.
2. Extent of the surface area.
3. Density of the air.
4. The angle of inclination of the airfoil to the air stream.

All this may be stated somewhat as follows:

$$F \sim R^n \alpha \rho S V^2.$$

F is wind reaction, α is the **angle of attack** of the wing, ρ is the density of the air, S the surface area, V the air velocity, R the **Reynolds number.**

If a proper constant K be inserted, the similarity can be made into an equality. K may also be made to include the effect of Reynolds number, angle of attack and air density. The equation is then simplified to:

$$F = KSV^2.$$

This reaction is neither perpendicular nor parallel to the wind stream. It is convenient to divide it into its components of lift and drag. Letting K_L and K_D be the corresponding coefficients,

$$\text{Lift } L = K_L S V^2,$$

$$\text{Drag } D = K_D S V^2.$$

There will be a different value of K for each angle of attack and each R, although the effect of the latter is usually minor.

The defect of this equation is that K is not dimensionless, as a true coefficient should be; also, the formula is not flexible with respect to air density. If it were rewritten.

$$R = C\rho S V^2,$$

C would be dimensionless. The equation is usually written thus for drag,

$$D = C_d \frac{\rho}{2} S V^2,$$

because $\frac{\rho V^2}{2}$ is the pressure necessary to give air of density ρ a velocity of V. This is called the dynamic pressure. The drag is also $C_d q S$, where q stands for dynamic pressure. The drag coefficient C_d varies with angle of attack, but it is dimensionless. The wind tunnel test is used to establish the law of variation, and the results are plotted as a drag curve, with the coefficient of drag as the ordinate, and either coefficient of lift or angle of attack as the abscissa.

A few typical coefficients of drag are:

1. Flat-plate normal to air stream. Average value 1.28 often used, although subject to variation from Æ and R.N.

Flat-plate parallel to air stream. C_D = skin friction coefficient as there is no turbulent wake. Varies. 0.002–0.008 depending on initial turbulence and R.N.

2. Sphere (S = projected area), about 4×10^5 critical R.N. Laminar boundary, 0.45; turbulent 0.1.

3. Cylinder, axis transverse to air stream (S = projected area), about 4×10^5 critical R.N. Laminar boundary, 0.7; turbulent, 0.3.

4. Thin wing, infinite Æ, R.N. 3.5×10^6. $C_{Dp} = .01$.

5. Clark Y wing, Æ 6, R.N. 3.5×10^6. $C_D = .009 + .06\, C_L^2$.

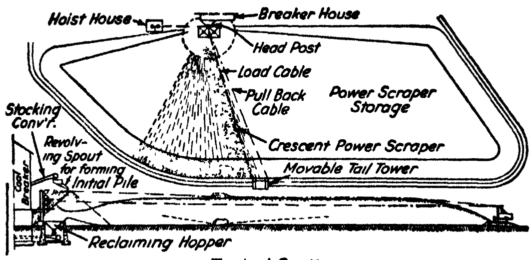
6. Airplane. $C_D = C_p + C_L^2/\pi$ Æ. C_p varies greatly as it depends on aerodynamic cleanliness (fairing, retraction of wheels, cowling of engine, etc.). (F.T.M.)

DRAG FOLDS. The smaller folds included in major folds. Produced by the shearing stresses set up within a fold by the relative movements of strata parallel to their bedding planes. (R.M.F.)

DRAG LINE. The drag-line excavator consists of a turntable on wheels or caterpillar treads, which supports the excavating machinery. A long **boom** is pivoted at its lower end to the turntable, and guyed at its outer end by a rope **sheave.** Extra long booms are characteristic of the drag-line excavator because the loading of the bucket is by scraping action in contrast to the shoveling action of a grab bucket. By the use of the boom, to which is attached the scraper, with the intermediary of a block and tackle, the operator can place the scraper bucket at a distance of 25–100′ from the position of the excavator. The scraper has attached to it a drag line which is wrapped around a powered drum in the cab. As this drag line is reeled in, it drags the scraper bucket and fills it, after which it is hoisted and dumped wherever wished. The drag-line excavator has been built in very large capacities, and is especially suitable for such work as levee building, **borrow pit** work, etc.

The drag-line scraper is a means for stocking-out bulk material to storage and reclaiming the same. It is comparatively low in first cost, and adaptable to a stor-

age lot of irregular area. A head post and machinery house is located at the point from which stocking-out begins, and to which reclamation moves. A movable tail tower may be operated at different points along the edge of the storage lot farthest from the head post. Between the tail tower and head post is an endless wire cable, to which is attached a scraper bucket. This passes over the drive sheave in the head tower. The drive may



Typical Section

Storage and reclamation by drag scraper.

be reversed, and the bucket caused to move out on the stock pile and then be returned, scraping up a full load of loose material as it comes. Typical arrangement of the drag scraper is shown in the accompanying figure. (F.T.M.)

DRAGON FLY. Insecta, Odonata. Large insects of powerful flight which eat other insects caught in the air. The immature insect is aquatic and predacious. The order is composed of dragon flies and damsel flies only. All have four slender net-veined wings and long slender bodies, but the dragon flies have fore and hind wings of slightly different shape and hold them extended when at rest. Also called Devil's darning needles. (A.W.L.)

DRAGON'S BLOOD. **Resins.**

DRAGONET. Pisces, Teleostei. *Callionymus.* Brightly colored, marine shore fishes (**Pisces**), limited to the Palaearctic region with the exception of a few tropical species in the Pacific Ocean. (A.W.L.)

DRAIN. In surgery, this term refers to any appliance placed in a wound to provide for escape of discharge or drainage. A common drain for small infections is a small piece of rubber or gauze. In abdominal cases, where drainage is required, the cigarette drain is most commonly used. This is made up of several layers of gauze surrounded by a sleeve of thin rubber sheeting. A Penrose drain is a thin tube of rubber sheeting without any gauze filling. Soft rubber tubing of all sizes is also commonly used. (R.S.M.)

DRAINAGE. The removal of water from any particular locality constitutes the action of drainage. Natural drainage is embodied in the rivulets, streams, and rivers to which surface and subsurface water is drained. Artificial drainage is used for a wide variety of purposes. Drainage in pipes is very common, especially in removing the water-floated wastes from human habitations. The drainage from sinks, lavatories, baths, and toilets constitutes a special phase of plumbing. All such drainage is accommodated in pipes. The principal drainage arteries for such a system are cast iron pipes with bell and spigot joints which are made water-tight by calking. Outside the building such drainage systems connect to the regular terra cotta or other type sewer drains of the sewerage system. Secondary drains are usually 1¼″ or 1½″ screwed iron pipe.

Artificial drainage of surface waters for the purpose of drying, or partly drying, a certain area of land, or for the purpose of intercepting water on its natural way toward a particular tract, can be accomplished by the use of ditches which are pitched in the direction in which the water is to be removed. Swampy, marshy land is often drained by this method.

Subsurface drainage systems are used where a ditch would be undesirable, as on a playing field. The subsurface drain can be a French drain or a pipe drain. A French drain is a deep ditch filled to a short distance below the surface with loose rock, the larger rock being at the bottom. Due to the larger friction loss in a drain of this type, it must be laid to a steeper gradient than that used in the pipe drain. In a subsurface pipe drain terra cotta drain tile is laid end to end wth slightly open joints. A fill of loose materials, such as crushed stone or gravel, is laid around the open joints so that water which enters this porous area will seep through the open joints into the pipe drain. (F.T.M.)

DRAVITE. **Tourmaline.**

DRAWING. One use of the word drawing is in reference to an operation performed on metal. The metal is originally in the form either of sheets, solid blanks, or pierced billets. These are formed in suitable dies into many different shapes, such as hollow cylinders, cup-like parts, or solid parts of various shapes. Pipe, wire, various structural shapes, are often formed by drawing. Drawing tends to reduce the thickness of the metal. (See **Wire Drawing, Cold Working, Stamping, Ductility, Forming, Press Working.**) (F.T.M.)

DRAWING REPRODUCTION. Modern drafting-room practice requires penciled drawings either on tracing paper, or on tracing cloth, which is made of cotton, and treated and sized to provide a suitable working surface. Since original drawings or tracings are never sent into the shop, and are, as a matter of fact, infrequently used in the drafting department itself, some method of reproduction is necessary. Blueprinting is one of the oldest methods, and is effected by placing the tracing on a sheet of paper or of cloth sensitized with iron salts and exposing the two to sunlight or an electric-arc lamp. After exposure, the print is washed in water and dried. To insure permanency and intensification of color, blue prints are sometimes washed with a potassium bichromate solution. The resulting print has a dark blue background and white lines and figures. Brown prints, having white lines on a dark background, are made in a manner similar to blue prints, but Vandyke paper is used. The prints require fixing in a "hypo" solution.

Black-line and blue-line positive prints, having dark lines on a white background, may be made from blueprint or Vandyke originals, but may also be produced directly from tracings by using specially prepared paper, which is developed by covering one side of the paper, after printing, with a developing and fixing solution. Ozalid prints are positive prints made by printing directly from tracings and developed dry in the presence of ammonia vapor. The prints may be obtained with red, blue, or black lines on a white background. Reproduction on transparent foil sheets can also be obtained by the process.

The Photostat process is a direct copying process whereby photographs of maps, drawings, prints, and tracings may be made, developed and fixed. The copy may be enlarged or reduced as desired. When made from original pencil or ink drawings or tracings, Photostat prints have a dark background and white lines. Positives may be obtained by making a second print from the first (negative) Photostat. (H.C.H.)

DREDGE. An excavating machine for use in river, harbor, or drainage work, is a dredge. A characteristic application of the dredge is in submarine excavation. Dredges are usually floated on water-tight hulls. There

are several types, which may be classified according to the way they excavate. The dipper dredge, which is the more common type, is very similar to a locomotive crane, except that it is mounted on a floating hull. Its digging equipment consists of a dipper or grab bucket, which is able to dip as deep as 50′ below the water surface. This type of dredge may be used in dredging channels or in cutting a wide drainage ditch provided the ditch is large enough to float the dredge. This dredge will dig its own waterway through land, and is particularly useful for drainage work. A dredge where the excavating is done by a number of buckets placed on an endless chain is known as an elevator dredge. A bucket chain is able to elevate the spoil considerably higher than other types. It is frequently used to raise sand and gravel from a stream bed.

The hydraulic dredge digs by suction of the spoil material from the bottom. A large pipe is lowered to the area to be dredged. A large power-driven rotary cutter is rigged in front of the entrance end of this pipe. Operation of the cutter breaks up the soft material of the bottom so that it may readily be transported by a current of water. A water pump attached to the upper end creates a powerful flow of water through the pipe which picks up and carries the loose material near the mouth of the pipe. Large, specially designed centrifugal pumps create the flow. Dredges are usually steam-driven. The larger sizes contain living quarters for the crew. (F.T.M.)

DREIKANTER. Literally a 3-cornered or 3-edged pebble. A term of German origin signifying a pebble that has been sculptured or faceted by natural sand-blasting. Such pebbles are usually considered to be proof of the semi-arid or even desert condition under which they have been formed, but they may also be formed in pluvial climates provided that the **regolith** is composed of porous and shifting sands such as compose glacial sand plains and coastal beaches. They are also called gibbers or glyptoliths. (R.M.F.)

DRESSING. **Grinding.**

DREWITE. A term proposed by R. M. Field in 1918 for pure **calcium** carbonate muds of organic chemical origin. Drewite probably forms the bulk of the fine-grained unfossiliferous **limestone** from the **pre-Cambrian** to the present. Named after G. H. Drew, a pioneer in the study of marine bacteria. (R.M.F.)

DRIER. **Pigments, Paints, Varnishes.**

DRIFT. In mechanics a drift is a hand tool somewhat resembling a punch, but used to drive pins in or out of deep holes. The drift is made slightly smaller than the diameter of the hole.

In structural engineering the term drift pin refers to a tapered steel pin which is used during the fabrication of a member to hold the individual parts together before the fitting-up bolts (bolts which are necessary to draw the parts together subsequent to riveting) are inserted in the **rivet** holes. Drift pins are also used together with bolts in steel erection to fasten the members to the **gusset plates** or other connections before the field rivets are driven.

In geology, the use of the term drift came about in the following way. Before Louis Agassiz propounded his theory that extensive deposits of sand, gravel, boulder clays, etc., of Northern Europe and North America were the result of the action of great continental ice sheets, it had been suggested that during some period when the land had stood at a lower level, ice bergs were swept from the north over the continents and, melting, dropped their loads of detritus. Thus some of the material which we now know to be of glacial origin was called drift, because it was believed to have been "drifted" to its place through the agency of ice. This was the theory of Sir Charles Lyell as a substitute for the still older theory of the diluvialists who believed that these glacial deposits were positive evidence of the "deluge." Geologists have retained the term drift to designate all unconsolidated sediments which are determined to be of glacial origin, and still further divide drift into stratified drift and unstratified drift or till. For "ether drift," see **Ether** and **Michelson-Morley Experiment.** (F.T.M., R.M.F.)

DRIFT METER. The instrument used in **air navigation** to measure the angle between the **heading** of a plane and the **track** being made good, is called a drift meter.

The simplest form of drift meter consists of a circular plate of heavy glass set in the floor of the cockpit in front of the pilot. The plate may be rotated within a ring on which degrees of angle are marked to the left and right of a zero mark. This zero point is in the direction of the forward end of the longitudinal axis of the plane. The plate has a series of parallel lines ruled on it. With the plane in level flight the pilot can look down through the plate and rotate it until objects on the ground are moving parallel to the lines. Under these conditions the lines on the plate will be in the direction of the track being made good, and the angle between the heading and this track may be immediately read on the scale.

Many modern and complicated types of drift sights have been devised but all of them operate on the fundamental principle described above. In some modern drift sights, a **gyroscopic** stabilizing system holds the grid lines level even though the plane is not flying level. Astigmatizers are frequently incorporated to assist in measuring drift angle, particularly when flying over water.

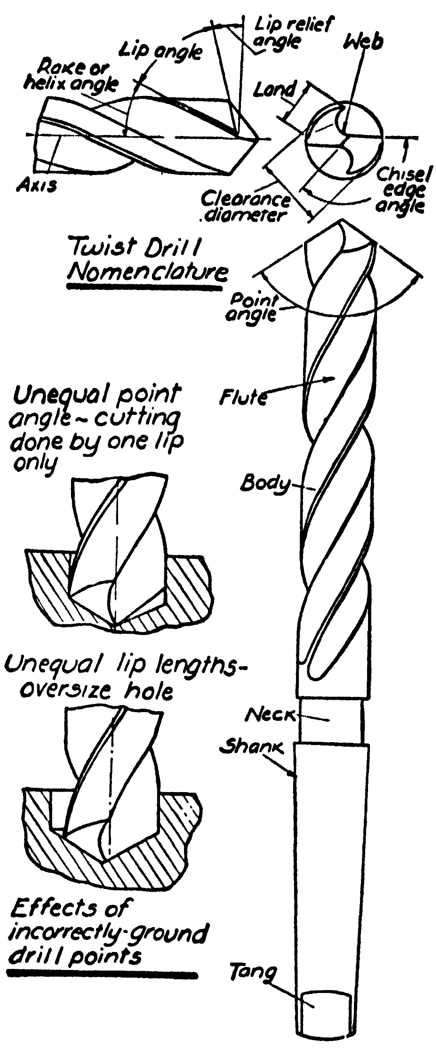
In some modern drift sights a system is incorporated so that ground speed may be determined. A pair of wires is marked on the grid, perpendicular to those set parallel to the apparent motion of the ground. The time required for an object on the ground to move from one of these wires to the other will be proportional to the ground speed. The distance of the plane from the ground must be accurately known, and the objects observed must be directly below the plane to obtain an accurate value of ground speed. (W.K.G.)

DRIFTING. **Forging.**

DRILLING. Originating a cylindrical hole with a one- or two-lipped straight-fluted or twist drill. (Contrast **Boring, Reaming, Trepanning.**) The twist drill is the most widely used tool for cylindrical holes. In drilling a hole, the point of the drill is forced into the work, crushing the material immediately beneath the web, and thereby allowing the two lips or cutting edges to cut. A two-lipped twist drill will originate a true cylindrical hole if both lips are of the same length and at the same angle with the axis of the drill, and if the axis of the drill and its axis of rotation are coincident. The point angle of a twist drill is generally 118° for drilling cast iron or steel; the lip relief angle is from 12 to 15°, and the chisel edge angle from 120 to 135°. The helical flutes provide rake for the cutting lips so as to curl the chips; they furnish a path for the escape of the chips and serve as channels for lubricants or coolants to reach the point of the drill. The drill is guided primarily by the two lips but also by the margin or full-diameter edge. That portion of the drill immediately behind the margin is reduced in diameter to minimize the friction between the drill and the walls of the hole. The web is the central section that connects the two outer helical portions of the drill.

There are three general types of drilling machines: the bench drill press, the upright drill press, and the

radial drill press. In all three types, the spindle rotates in a sleeve or quill which does not rotate but is free to move axially to provide the necessary feed for the drill. In the bench drill, both the table knee and the head carrying the spindle are adjustable for various classes of work. In the upright drill press, the spindle sleeve supports are fixed, and all adjustment for different classes of work is made by moving the table, which is accomplished by turning the elevating crank. The table can be moved in a horizontal plane, clamped at any point or, if desired, swung out of the way so that large work may be placed on the base. The machine is equipped with a ratchet lever for hand-feeding the drill. A hand wheel is fastened to a worm shaft whose worm engages a worm gear on the pinion feed shaft, giving a motion much finer than that obtained by using the hand lever. Speed changes in bench drills are effected by cone pulleys; in upright drill presses either cone pulleys or a geared head is used.



The radial drill has a column which may be rotated about the base. On the column is a radial arm which moves in a horizontal plane with the column, but may also be moved in a vertical plane. A head carries a spindle, and may be moved radially along the arm. The radial drill is therefore adapted to heavy work where it is easier to move the drill than the work. Spindle speed and feed changes are effected by gearing. A sensitive drill is a vertical or upright machine of comparatively light construction adapted to very high speeds and used for delicate work.

Drill-press spindles generally have a Morse taper hole in the spindle. Twist drills with taper shanks may be fitted directly to the tapered spindle hole, but in many cases the taper shank of the drill is smaller than the spindle socket. In such an instance, a collet or sleeve is employed. A drill collet is a conical sleeve which has an inside taper fitting the shank of a twist drill, and an outside taper fitting the socket in the drill-press spindle.

Straight-shank twist drills which have a cylindrical shank of the same diameter as the drill itself are generally held either in 3-jaw or 2-jaw **chucks.** Both types of chucks are generally held by inserting an arbor in a tapered hole in the body of the chuck, which in turn is held by inserting its tapered shank in the spindle socket.

For wood drilling, the work can ordinarily be held by hand. Except where small holes are drilled in comparatively large or heavy parts, however, metal drilling requires so much torque that the work should be held in a vise or be clamped to the drill press table.

Two-lipped twist drills with either taper or straight shanks are satisfactory cutting tools for holes in cast iron and steel. Straight-fluted drills are used for copper or brass; they manifest less tendency to "dig in" than the helically fluted tool. For heavy feeds and comparatively deep holes, oil-hole drills are employed. These drills have holes drilled from the solid metal through the body of the drill so that lubricants can be pressure-fed to the drill points. The lubricant not only assists in the cutting operation, but also facilitates the removal of the chips by forcing them out along the flutes of the drill. Oil-hole drills, with holes for lubricant in the body of the drill, may be employed in drill presses but they are generally used in automatic machinery where the drill is stationary and the work rotates.

Drilling speeds vary from 40 ft. per min. for cast and alloy steels to 300 ft. per min. for brass and bronze. Drilling feeds vary from .002″ per revolution for ⅛″ diameter drills to .015″ per revolution for drills 1″ in diameter and over; a representative figure is .001″ per 1/16″ diameter of the drill. (H.C.H.)

DRIVEN ANTENNA. Directional Antenna.

DRIVING FORCE. Gas Absorption.

DRIZZLE. Hydrometeors.

DROMEDARY. Mammalia, Artiodactyla. An Arabian camel of a breed used for riding. Incorrectly applied to the Bactrian camel. (A.W.L.)

DRONGO. Aves, Passeriformes. The king crows of southern Asia and Africa. Birds (**Aves**) of several species, mostly black, forming a family not closely related to the true crows. (A.W.L.)

DROP FORGING. Forging.

DROPSY. Edema.

DROSOPHILA. Insecta, Diptera. The name of a genus of fruit flies or pomace flies. Because of the extensive use of these insects, and especially *Drosophila melanogaster,* in the study of heredity the name of the genus has become more commonly used than the vernacular names. (See **Heredity.**)

These flies are small and usually light-colored insects which frequent decaying or fermenting fruit. They are attracted by vinegar, cider, and fruit wastes even when fresh and so are often common about the house during the canning season. The larvae live in the fermenting material. (A.W.L.)

DRUGS. A wide variety of sources has been tapped to furnish materials to combat disease and its effects and to promote health. Many of the products of vegetable, animal and mineral origin in use were recognized many centuries ago as possessing therapeutic value. Great improvements have been made in this field in recent decades. The desired products have been obtained in greater purity and of greater efficacy. In many cases individual or group substances have been isolated and synthesized. The role played by particular drugs in promoting recovery or improvement of health has been studied. Many drugs are used, not for their function in combating directly the causative agent of a disease, but for their indirect action (1) upon its toxic products, (2) by inducing a **biochemical** reaction, which causes the body organism to produce substances to combat the disease organisms or their toxic products, (3) by inducing physiological reactions which enable the patient to resist those reactions caused by the disease.

Vegetable drugs may occur in all parts of plants, but are particularly abundant in such storage regions as seeds, roots and bark. Many used by man are found in the leaves, and a few in the flowers. Their function in the plant is a debated one; perhaps they are by-products of the plant's metabolism, or they may be energy-yielding reserves stored until needed. The poisonous nature of many of them suggests the thought that they may be designed for protection against attacks by insects and other animals. Drug substances in the plant fall into several classes. One of these contains the alkaloids, nitrogenous organic substances which react with acids. Many of these alkaloids are powerful poisons; all of them are toxic to animals. In another group of drug substances are the glucosides, complex organic substances which, when acted upon by certain **enzymes**, break down into **sugars** plus other compounds. Other medicinal substances are found in **resins, tannins, gums,** and **oils.**

In former times the number of plants used medicinally was very great. Many were known by primitive man and the knowledge of their value handed down from generation to generation. In modern times the number of plants used medicinally has diminished greatly, partly because men learned how absurd was the reason for their use and how slight their value, and partly because other drugs, many of them prepared synthetically, replaced the natural products. But many continue to be of great benefit to man.

Every part of the world yields drug plants. In a very few instances, these plants are cultivated. Mostly, however, the plants are gathered wild. Usually all that is necessary to prepare the crude drug for market is to gather and dry the plants. They are then shipped to the wholesale buyers. If the plant itself is to be used as a drug, it is thoroughly cleaned and then ground. More frequently the preparation is an elaborate process calculated to free the pure drug from the tissue in which it occurs.

Common vegetable drugs are **belladonna, ipecac, quinine, coca, digitalis, strychnine, opium, castor oil, camphor,** and **menthol.**

The narcotics include very valuable drugs which, taken in moderate doses, properly prescribed, relieve pain and produce sleep, but in large doses cause stupor, or coma, and commonly convulsions. Among the habit-forming drugs are **opium** and its derivatives, **coca,** and hashish from **hemp.**

The pioneer workers in pharmacology acquired considerable empirical information about methods of extraction of drugs from natural materials by water, hot water, alcohol and other solvents, and combinations of solvents. In the more purely scientific field, some outstanding discoveries are the **hypnotic,** chloral hydrate (1867), the **antipyretic,** acetanilide (1885), the **antisyphilitic,** salvarsan (1910), the **thyroid** principle, thyroxin, insulin (used in **diabetes**), sulfanilamide (first commercially produced in 1937) and other "sulfa" drugs, **Atabrin** and **plasmoquin** to combat malaria, and **penicillin.**

Refinements in the technique of biological assay have contributed largely to the progress in the study of **vitamins, enzymes,** and **hormones.** By means of the methods that have been developed in this branch of science the effects of complex mixtures of substances are measured by their physiological reaction on test animals. In this way the direction of physiological research is controlled, even though the chemical nature of the substance under examination is entirely unknown.

Some substances that are mentioned elsewhere may be classified as drugs, since they are of the greatest importance in treating disease and promoting health. These are (1) the serums and **vaccines** usually produced in animals, directly or indirectly, by biochemical reactions of **bacteria.** In some cases the bacteria produce an attenuated strain which is utilized. Vaccines are used to induce a mild attack of the disease or a related disease. By this means protective substances are formed in the system of the patient. The protective substances are added directly to the system in other cases. (2) The glandular products, of which **adrenalin,** the active principle of the **suprarenal gland,** and **thyroxin,** the active principle of the **thyroid gland,** have attracted widespread attention, have been studied physiologically on test animals, and on man, and both have been synthesized. (3) The **vitamins** have been shown to be necessary for the normal functioning of the organism as well as necessary for the avoidance and cure of certain deficiency diseases.

Representative drugs may be classified upon the basis of physiological function as follows:

1. *Antiseptics.* Sodium hypochlorite, iodine, alcohol, silver nitrate, tannic acid, picric acid, potassium permanganate, iodoform, chloramine T, dichloramine T, hydrogen peroxide, 4-hexylresorcinol (urinary disinfectant), phenol, mercuric chloride solution (very poisonous), boric acid, argyrol (colloidal silver), menthol, phenyl salicylate (salol), triphenylmethane dyes, both basic (very poisonous) and acidic, flavine dyes (proflavin, acriflavin, rivanol —active in the presence of proteins).

2. *Anesthetics.* *a.* General: ether, chloroform, nitrous oxide, ethylene, cyclopropane, avertin, alcohol. *b.* Local: cocaine, novocaine, stovaine, production of cold by evaporation of ethyl chloride.

3. *Soporifics, hypnotics.* Bromides of sodium, potassium, ammonium, calcium, lithium, chloral hydrate, sulfonal, trional, tetronal, ethyl carbamate, hedronal, barbital (Veronal), phenobarbital (Luminal), diallybarbituric acid, allylisopropylbarbituric acid, and other barbituric acid compounds.

4. *Antipyretics, analgesics.* Acetanilide, acetphenetidin (Phenacetin), acetyl salicylic acid (Aspirin), antipyrine, pyramidon, Atophan, Novatophan.

5. *Purgatives, laxatives, cathartics.* Citrates, tartrates, acetates, phosphates, sulfates of magnesium, sodium, potassium, phenolphthalein, castor oil, croton oil, cascara, rhubarb, aloin, podophyllin, and other plant principles.

6. *Circulatory depressants and stimulants.* *a.* Depressants: glyceryl trinitrate, erythritol tetranitrate, mannitol hexanitrate, isoamyl nitrite, sodium nitrite, benzyl nitrite, aconite, veratrine. *b.* Stimulants: digitalis, digitoxin, digitalin (not digitonin), caffeine, adrenalin, ammonia, camphor, cocaine.

7. *Parasympathetic nerve paralyzers and stimulants.* *a.* Paralyzers: atropine, homatropine. *b.* Stimulants: pilocarpin, physostigmine, histamine.

8. *Mydriatics and myotics.* *a.* Mydriatics (causing dilation of the pupil): belladonna, atropine, strychnine, scopolamine (hyoscine). *b.* Myoptics (causing contractions of the pupil): pilocarpine, eserine.

9. *Dieuretics.* Caffeine, theobromine, theophyline (theocin), hexamethylenetetramine.

10. *Emmenagogues.* Ergot, apiol, rue, tansy.

11. *Emetics.* Ipecac, potassium antimony tartrate (tartar emetic), apomorphine, mustard.
12. *Expectorants.* Ammonium chloride, ammonium anisate, woodtar creosote, eucalyptus, terebene.
13. *Astringents.* Tannic acid, alum.
14. *Counterirritants.* Mustard, capsicum, turpentine, chloroform, cantharides.
15. *Antiarthritics.* Lithium citrate, cinchophen, salicylates and iodides of sodium, potassium, ammonium, calcium, strontium, lithium.
16. *Alteratives.* Iodides of sodium or potassium, colchicum, taraxacum.
17. *Antacids.* Sodium bicarbonate, magnesium hydroxide and oxide, bismuth basic carbonate.
18. *Tonics, bitters.* Cinchona, nux vomica, ferric citrate, sodium hypophosphite, glycerophosphates of sodium, potassium.
19. *Narcotics.* Morphine, codeine, heroin, scopolamine (hyoscine).
20. *Demulcents.* Glycerol, olive oil, gelatin.
21. *Drugs for specific diseases.* For counteracting: *a.* malaria: quinine, Atebrin, plasmoquin. *b.* syphilis: arsphenamine (Salvarsan, Ehrlich 606), neoarsphenamine (Neosalvarsan). *c.* leprosy: esters and sodium salt of chaulmoogric acid. *d.* sleeping sickness: tryptane blue (Bayer 205). *e.* acute rheumatic fever: salicylic acid compounds.
22. *Enzymes.* Pepsin, pancreatin.
23. *Hormones.* Adrenalin (active principle of the suprarenal gland), thyroxin (active principle of the thyroid gland), insulin (active principle of the pancreas), pituitary extract (active principle of posterior lobe of pituitary gland).
24. *Vitamins.* (See **Vitamins.**) (R.K.S., R.M.W.)

DRUM. Pisces, Teleostei. Fishes (**Pisces**) of numerous species, mostly marine, constituting the family Sciaenidae. The **sheephead** is a North American fresh water species of some food value. (A.W.L.)

DRUMLIN. A drumlin is a hill composed of glacial material of unstratified and heterogeneous character usually about 100′ in height and ¼–½ mile in length, oval in shape, and with its long axis parallel with the general direction of ice movement. Sometimes a mass of bed rock seems to have been the anchor about which the glacial till was deposited. Drumlins are known, however which contain no bed rock core. Drumloid-shaped hills similar to the smaller glaciated rock features called **roches moutonnée** are sometimes called rock drumlins. (R.M.F.)

DRUPE. Fruit.

DRUSE. A cavity, usually in a **sedimentary** rock, the walls of which are encrusted with minerals which have been derived, through underground solutions, from the rocks in which the cavities were formed, by **solution.** (R.M.F.)

DRY PIPE. Steam Purifier.

DRYING. Distillation, Evaporation and Drying.

DRYOPITHECUS. Paleontology of Man.

DUANE AND HUNT'S LAW. The quantum-energy law for the generation of x-rays. When a cathode particle in an x-ray tube strikes the target, its energy may all be transformed into heat, or it may excite an atom of the metal to emit a quantum of x-radiation. (See **X-rays and Quantum Theory.**) If all the cathode particles have the same energy *Ve* (voltage times electronic charge), some may give rise to low-frequency quanta and have energy left to heat the target, others may excite quanta of higher frequency and have less energy to spare. But no quantum can be emitted of frequency and energy higher than that corresponding to the original energy of the electrons. This is Duane and Hunt's law. It is expressed by the so-called Planck-Einstein equation. If the highest frequency emitted is ν_{max}, and h is Planck's constant, the equation may be written $h\nu_{max} = Ve$. It follows that for a given voltage V, the **x-ray spectrum** must terminate abruptly at the frequency Ve/h. (L.D.W.)

DUCK. Aves, Anseriformes. Swimming birds (**Aves**) of moderately large size with heavy bodies, short legs, webbed feet, and broad flattened beaks with sieve plates at the sides. In common usage the term includes the closely related **teals, sheldrakes,** and **mergansers.** With the exception of the mergansers, which have narrow beaks with serrate edges and live chiefly on fish, the ducks eat rice and other plant products, with some insects and other small animals. They are among the leading game birds and many wild species have very palatable flesh. Many species have been domesticated and interbred with the common domestic duck.

Among species which have received special names are the **gadwall, widgeon, mallard, shoveler, pintail, bufflehead, scoter, and canvas-back.** (A.W.L.)

DUCKBILL. Mammalia, Monotremata. *Ornithorhynchus.* A primitive egg-laying mammal of Australia, also called the platypus and the duckmole. It is about 18″ long and has close fur somewhat like that of the moles. The muzzle is broad, flat, and naked, resembling the beak of a duck but not horny. The feet are broad and webbed. Duckmoles are found in the streams of southern and eastern Australia. They nest in burrows in the banks and deposit two small eggs at a time. The young are nourished with milk secreted by the mother. (A.W.L.)

Duckbill or Platypus. (*N. Y. Zool. Soc.*)

DUCT. A tube-like structure providing for the passage of secretions or excretions from any organ. (D.M.H.)

DUCTILITY. Ductile metals are capable of undergoing considerable amounts of plastic deformation before developing shear cracks or failing by rupture in tension. Ductility is generally associated with tensi'e properties or the ability to be cold drawn, as in wire drawing or sheet stamping operations. Per cent elongation in the **tension test** is the usual measure of ductility. (See **Malleability; Metals, Physical Properties of.**) (R.H.H.)

DUCTLESS GLAND. Endocrine Gland.

DUCTUS COMMUNIS. A passage connecting the ducts of all female organs of reproduction with the genital **atrium** in the flatworms. (A.W.L.)

DUGONG. Mammalia, Sirenia. A marine **mammal,** *Halicore,* found along the shores in the Oriental region. Related to the American manatee. It has a blunt muzzle, a broad horizontal tail, and pectoral flippers. These animals eat seaweed and are caught for their flesh and oil. (A.W.L.)

DUIKERBOK. Mammalia, Artiodactyla. Small South African **antelopes.** Daintily built, with large ears and, in the male, short straight horns. (A.W.L.)

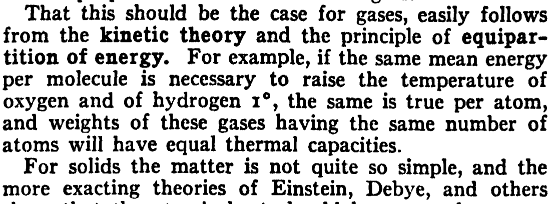
DULONG AND PETIT'S LAW OF SPECIFIC HEATS. It has long been known that the atomic heats of the great majority of elements have nearly the same value at room temperature; in fact, the thermal capacity of a gram atom of most elements is not far from 6 calories per degree. Dulong and Petit expressed this by stating that the specific heats of elements are in inverse proportion to their atomic weights.

That this should be the case for gases, easily follows from the **kinetic theory** and the principle of **equipartition of energy.** For example, if the same mean energy per molecule is necessary to raise the temperature of oxygen and of hydrogen 1°, the same is true per atom, and weights of these gases having the same number of atoms will have equal thermal capacities.

For solids the matter is not quite so simple, and the more exacting theories of Einstein, Debye, and others show that the atomic heat should be expected to vary with the temperature. According to Debye, there is a certain characteristic temperature for each crystalline solid at which its atomic heat should equal 5.67 calories per degree. Einstein's theory expresses this temperature as $h\nu_m/k$, in which h is **Plack's constant,** k is **Boltzmann's constant,** and ν_m is a frequency characteristic of the atom in question vibrating in the crystal lattice (see **Crystal Structure.**) (L.D.W.)

DUMMY ANTENNA. Antenna, Dummy.

DUNE. Dunes are elliptical or crescent-shaped mounds of sand which may reach a height of a hundred or more feet The windward slopes of dunes are gentle, the lee sides steep, if crescentic in shape the convex side faces the direction from which the wind is blowing. The crescentic-shaped dunes are called barchans. Sand



Types of sand dunes. (*After Walther and Cornish.*)

blown up the windward side drops down the lee slope causing the dunes to migrate slowly. Dunes are common and characteristic phenomena of lake and sea beaches, semi-arid regions, and particularly deserts, but also may develop on any dry, sandy soil in a relatively humid region where there is a lack of vegetation. Ancient geologic formations which may have originated as dunes may be identified by their peculiar type of **cross-bedding,** and by the peculiar texture of the sand. (R.M.F.)

DUNITE. Peridotite.

DUNLIN. Aves, Charadriiformes. *Tringa.* A common European shore bird; a **sandpiper.** Also called the ox bird. (A.W.L.)

DUNNOCK. Aves, Passeriformes. The European hedge sparrow, ***Prunella modularis.*** (A.W.L.)

DUODENUM. That portion of the intestinal tract immediately beyond the stomach. It begins at the **pylorus** and extends to the beginning of the **jejunum.** Horseshoe-shaped, it forms a curve around the head of the pancreas. The secretions of the duodenum are alkaline. Into it empty the bile duct from the liver and two ducts from the pancreas. The greater part of the digestion of food begins here.

The duodenum is a common site for ulceration. (See **Peptic Ulcer.**) (D.M.H.)

DUODIODE. Tube, Electronic.

DUPLEX PUMP. The kind of **direct-acting pump** most often found has two steam cylinders arranged side by side. The water cylinders are also two in number, arranged side by side. The duplex pump is in reality a twin-cylinder **pump.** It has two steam pistons, two water pistons, and two piston rods. The special advantage of the twin arrangement comes from the convenience of valve operation in a twin-cylindered direct-acting pump. The steam valve of one of the cylinders is caused to reciprocate properly in its valve chest with a motion derived from the travel of the piston rod of the other.

The mechanism is quite simple. A collar block attached to the piston rod operates an oscillating type lever to one end of which is attached the steam valve. The motion of that piston rod moves the valve in the other cylinder, which then executes a pumping stroke as the steam enters and pushes against the piston. As that piston rod moves, it similarly operates the valve in the first steam cylinder, causing it to effect a pumping stroke. Thus in a duplex pump the valve action on one cylinder is derived from the stroke of the other, and pumping strokes are consummated alternately, first in one cylinder, then in the other. (F.T.M.)

DURAIN. The term proposed by Marie Stopes in 1919 for an ingredient of bituminous **coal,** occurring in bands. In thin, translucent sections durain is seen to be composed of reddish **spores** in a gray, granular **matrix.** (R.M.F.)

DURALUMIN. Aluminum Alloys.

DURCHMUSTERUNGEN. Bonner Durchmusterungen.

DURIRON. Alloys.

DUST DEVIL. Whirlwinds over sandy areas which pick up dust and sand, swirling the particles upward. They sometimes become fairly strong and reach hundreds of feet upward. (P.E.K.)

DUST STORM. Over dusty, dry, or desert areas strong winds which have picked up considerable dust and carried it to great heights. Sand storms are similar to dust storms. Three factors are necessary in the development of a dust or sand storm, (1) a dusty or sandy surface, (2) strong winds which can strike at the ground and pick up dust particles, and (3) a steep lapse rate, i.e., unstable air, which permits the dust to be carried to great heights.

Visibility in dust storms is usually only a few yards and sometimes reduced to night-like darkness. (P.E.K.)

DYADICS. Two **vectors** placed in juxtaposition neither with a dot $\cdot$ nor a cross $\times$ between them constitutes a dyad, as for example $\mathbf{ab}$.

Any polynomial of dyads, as $\mathbf{a}_1\mathbf{b}_1 + \mathbf{a}_2\mathbf{b}_2 + \cdots + \mathbf{a}_n\mathbf{b}_n$, is called a dyadic.

A dyadic is sometimes regarded as a **tensor** of the second rank.

The first vector of a dyad is called its antecedent and the second its consequent. The antecedents and consequents of a dyadic are respectively the antecedents and consequents of its constituent dyads.

In general, a dyadic is usually denoted by bold-face capital Greek letters, as $\mathbf{\Phi}$.

If the order of the vectors in each dyad of a dyadic $\mathbf{\Phi}$ is reversed, the resulting dyadic is called the conjugate of $\mathbf{\Phi}$.

Two dot products of a dyadic $\mathbf{\Phi} = \mathbf{A}_1\mathbf{B}_1 + \cdots \mathbf{A}_n\mathbf{B}_n$ by a vector $\mathbf{v}$ are defined thus:

$$\mathbf{\Phi}\cdot\mathbf{v} = \mathbf{A}_1(\mathbf{B}_1\cdot\mathbf{v}) + \mathbf{A}_2(\mathbf{B}_2\cdot\mathbf{v}) + \cdots \mathbf{A}_n(\mathbf{B}_n\cdot\mathbf{v}),$$

$$\mathbf{v}\cdot\mathbf{\Phi} = (\mathbf{v}\cdot\mathbf{A}_1)\mathbf{B}_1 + (\mathbf{v}\cdot\mathbf{A}_2)\mathbf{B}_2 + \cdots + (\mathbf{v}\cdot\mathbf{A}_n)\mathbf{B}_n,$$

both being vectors. In $\mathbf{\Phi}\cdot\mathbf{v}$, the dyadic $\mathbf{\Phi}$ is said to act as pre-factor, in the other case, as post-factor.

A dyadic acting as pre-factor or post-factor upon any vector produces a **linear vector function** of this vector.

Any dyadic $\mathbf{\Phi} = \mathbf{A}_1\mathbf{B}_1 + \cdots + \mathbf{A}_n\mathbf{B}_n$ can be reduced to the trinomial form $\mathbf{a}_1\mathbf{b}_1 + \mathbf{a}_2\mathbf{b}_2 + \mathbf{a}_3\mathbf{b}_3$, where $\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3$ are chosen arbitrarily.

Any dyadic $\mathbf{\Phi}$ can be expressed in the form

$$\begin{aligned}\mathbf{\Phi} = {} & a_{11}\hat{\mathbf{i}}\hat{\mathbf{i}} + a_{12}\hat{\mathbf{i}}\hat{\mathbf{j}} + a_{13}\hat{\mathbf{i}}\hat{\mathbf{k}} \\ & + a_{21}\hat{\mathbf{j}}\hat{\mathbf{i}} + a_{22}\hat{\mathbf{j}}\hat{\mathbf{j}} + a_{23}\hat{\mathbf{j}}\hat{\mathbf{k}} \\ & + a_{31}\hat{\mathbf{k}}\hat{\mathbf{i}} + a_{32}\hat{\mathbf{k}}\hat{\mathbf{j}} + a_{33}\hat{\mathbf{k}}\hat{\mathbf{k}}.\end{aligned}$$

This is called the nonion form of the dyadic.

A dyadic which is identical with its conjugate is called a symmetric dyadic; for it, we have $a_{ij} = a_{ji}$, i.e., $a_{12} = a_{21}$, $a_{13} = a_{31}$, $a_{23} = a_{32}$.

A dyadic is called anti-symmetric or skew-symmetric when it is equal to the negative of its conjugate; then $a_{ij} = -a_{ji}$, i.e., $a_{11} = a_{22} = a_{33} = 0$, $a_{12} = -a_{21}$, $a_{23} = -a_{32}$, $a_{31} = -a_{13}$.

If $\mathbf{\Phi}$ is symmetric, and $\mathbf{v}$ is any vector, then $\mathbf{\Phi}\cdot\mathbf{v} = \mathbf{v}\cdot\mathbf{\Phi}$.

A dyadic which, acting as pre-factor or post-factor upon a vector, produces the vector itself, is called an idemfactor or unit dyadic. Its standard form is

$$\mathbf{I} = \hat{\mathbf{i}}\hat{\mathbf{i}} + \hat{\mathbf{j}}\hat{\mathbf{j}} + \hat{\mathbf{k}}\hat{\mathbf{k}}.$$

Any dyadic can be resolved into a sum of a symmetric part and a skew-symmetric part.

Any symmetric complete dyadic $\mathbf{\Phi}$ can be reduced to the normal form:

$$\mathbf{\Phi} = a\hat{\mathbf{i}}\hat{\mathbf{i}} + b\hat{\mathbf{j}}\hat{\mathbf{j}} + c\hat{\mathbf{k}}\hat{\mathbf{k}},$$

where the coefficients a, b, c are positive or negative (scalar) constants, by a transformation of axes. (L.L.S.)

DYADS. Dyadics.

DYAS. The western European term for the Permian system where it is readily divisible into two parts. (R.M.F.)

DYE BLEACHING. A method of forming a subtractive color synthesis to be used in making a color photograph. In a mixture of colorants such as cyan, magenta and yellow, each colorant tends to be bleached by light of its complementary color since such light is the only light absorbed by that colorant. Thus, the cyan colorant tends to be bleached by red light and not by blue or green light.

If an integral tripack composed of gelatin layers colored with such light-sensitive dyes is exposed to light from an original subject or a color transparency, each colorant layer will be bleached by its complementary color, yielding a dye image in which the colors correspond to those in the original. Such a simple process of color reproduction has long been sought but without notable practical success. The difficulty of making the process sensitive enough and at the same time stable after the images have been formed, has prevented any successful commercialization. (H.C.C.)

DYE MORDANTING. Dye Toning.

DYE TONING. A method of colorant formation used in subtractive processes of color photography. The positive silver images are converted into a substance, such as potassium iodide, which has a strong affinity for certain dyes. Such substances are mordants and will hold the dye in the same position and in the same relative density as formerly occupied by the silver image. Dye toning is, therefore, often termed dye mordanting.

The mordant image is treated with a dye which is then held by the mordant while the film or plate is washed free of unattached dye. The mordants generally used work well with basic dyes. Such dyes are very brilliant although usually not very stable or fast to light. (H.C.C.)

DYES AND DYEING TEXTILE FIBERS. With few exceptions the dyestuffs in use for dyeing textiles, coloring foods, as chemical indicators, biological stains, antiseptics, and photographic sensitizers, are made industrially from the benzenoid **hydrocarbons, benzene, toluene, naphthalene, anthracene.** These hydrocarbons are colorless substances when observed in natural light. They show, however, slight absorption of light of wavelength outside the range of easy visibility to the naked eye, at the extreme edge of the spectrum. Such simple derivatives of these hydrocarbons are pure **phenol, hydroquinone,** the naphthols, anthranol, chlorobenzene, dichlorobenzene, benzenesulfonic acid, **aniline** and hydrazobenzene are likewise colorless to the naked eye, and some show slight absorption of light beyond the visible spectrum.

But nitrobenzene is of a pale yellow color, and azoxybenzene pale yellow. Thus, these two substances show some absorption of light in the visible spectrum. Finally, benzoquinone and azobenzene are highly colored substances, thus showing marked absorption in the visible spectrum. Quinones are the only carbon-hydrogen-oxygen compounds that as a class possess marked color. Azo-nitrogen compounds possess marked color. Some nitro-compounds are decidedly colored, others slightly, some scarcely. The table on page 487 is intended to make these results graphic.

The groups which distinguish these and other highly colored organic substances—chromogenes—are called chromophors (color producers).

CHROMOGENE	CHROMOPHOR GROUP
Quinones..........	Azo-compounds....	—N : N—
Nitro-compounds...	$—NO_2$

Chromogenes, although highly colored, are not dyes. Colored substances, in order to be classed as dyes, must be capable of permanent attachment to some other substance, such as cotton and linen, wool and silk, rayon, in such a way as to withstand the action of water and soap. Dyes for ordinary use should also be fast to sunlight.

Chromogenes are converted into dyes by the introduction of a secondary group, called an auxochrome (color fixing) group, such as (1) amino group ($—NH_2$, also for example, $—N\!\begin{smallmatrix}H\\CH_3\end{smallmatrix}$, $—N\!\begin{smallmatrix}CH_3\\CH_3\end{smallmatrix}$, $>NH$), (2) hydroxyl group (—OH), (3) carboxyl group (—COOH). Picric acid (2,4,6-trinitrophenol) is a dye, while T.N.T. (2,4,6-trinitrotoluene) is not a dye, although highly colored. Para-aminoazobenzene ($C_6H_5—N:N—C_6H_4(NH_2)(4)$) and para-hydroxyazobenzene ($C_6H_5—N:N—C_6H_4(OH)(4)$) are dyes, while azobenzene ($C_6H_5—N:N—C_6H_5$) and para-para-prime-azotoluene ($(4')(CH_3)C_6H_4—N:N—C_6H_4(CH_3)(4)$) are not dyes although highly colored. Alizarin (1,2-dihydroxyanthraquinone) is a dye, while anthraquinone, like naphthoquinone and benzoquinone, is not a dye although highly colored.

TABLE SHOWING HIGHLY COLORED DERIVATIVES OF BENZENOID HYDROCARBONS

Note: Highly colored substances (not dyes) are underlined once, dyes twice

Hydrocarbon	Selected Derivatives of Hydrocarbons				
Benzene	Phenol Dihydroxybenzenes (1, 2; 1, 3; 1, 4) Aniline Benzidine Chlorobenzene Dichlorobenzene Benzene sulfonic acid	Benzoquinone Hydrazobenzene	Azobenzene Aminoazobenzene Hydroxyazobenzene	Azoxybenzene	Nitrobenzene 4-Nitrophenol Sodium-4-nitrophenolate 2,4,6-Trinitrophenol 2,4,6-Trinitroaniline
Toluene	Cresols Orcinol Toluidine Tolidine Chlorotoluenes Toluene sulfonic acids	Toluquinone Hydrazotoluene	Azotoluene		Nitrotoluenes 2,4,6-Trinitrotoluene
Naphthalene	Naphthols Dihydroxynaphthalenes Naphthylamines Chloronaphthalenes Naphthalene sulfonic acids	Naphthoquinone			Nitronaphthalenes
Anthracene	Anthrols and Anthranol Dihydroxyanthracenes Anthramine	Anthraquinone 1,2-Dihydroxyanthraquinone (alizarin)			

Auxochromes increase the solubility of the dye over that of the chromogens, and the presence of the sulfonic acid group is of great importance in this respect (see **Thioalcohols**). Dyes must usually possess a basic or acidic nature. Basic dyes contain the amino auxochrome (forming salts, e.g., hydrochlorides), feebly acid dyes the hydroxyl chromophore, and acid dyes the sulfonic acid (more commonly) or carboxyl (less commonly) auxochrome (forming salts, e.g., sodium salt). The solubility of acid dyes is frequently attained by the use of the sodium salt.

The effect of increasing the weight of the dye molecule by addition of methyl ($—CH_3$), ethyl ($—C_2H_5$), amino ($—NH_2$) groups is to darken the color. For example, aminoazobenzene is pale yellow, diaminoazobenzene orange, and triaminoazobenzene brown.

As to the basic or acidic nature of the fibers to be dyed, wool and silk are proteins (see **Aminoacids**) and behave as acids towards bases, and as bases towards acids (that is, they are amphoteric) and are readily dyed directly by dyes of a basic or acidic nature. Cotton and linen, on the other hand, are cellulose (see **Carbohydrates**) and noted for their chemical inertness. These are scarcely affected by basic or acidic dyes. Rayons of cellulose are similar to cotton and linen in respect to dyeing, and rayons of cellulose acetate require special dyes.

The cellulose fibers are dyed directly by some dyes such as benzidines, primulines (both are amino dyes), curcumines (hydroxy dyes), by the use of **sodium** chloride or sodium sulfate solution. But generally these fibers are dyed by the use of mordants. In this process dyestuffs containing either hydroxyl ($—OH$) or carboxyl ($—COOH$) groups in their composition are used with a solution of **chromium, aluminum, iron, tin** or **copper** salt. Other dyes are used as mordant dyes, and other mordanting materials, for example, **tannic acid**, are used with basic dyes. With these salts the mordant dyes form a colored insoluble substance called a lake, which is permanently fixed in the fiber under the conditions of dyeing. The color is dependent upon the mordant used for a particular dye. **Cellulose** acetate fibers are dyed by ionamines, which are insoluble azo or anthraquinone dyes, temporarily converted into soluble derivatives by the introduction of the group $—CH_2SO_3Na$, and later split off in the dyeing process, leaving the insoluble dye on the fiber. Insoluble azo or anthraquinone dyes are also maintained in suspension in the dye bath by means of sulfonated castor oil. These dyes do not adhere to cotton, linen, or viscose, and therefore permit the operation of selective dyeing when other fibers are used with cellulose acetate.

In vat dye processes an insoluble dye is converted into a weakly acidic, alkali-soluble, colorless or leuco-compound. Upon immersion of the fiber in the dye bath and removal of the immersed fiber, the dye is fixed in the fiber by **oxidation** in the air. Indigo and anthraquinone dyes are typical vat dyes. **Sodium** hydro-

CHEMICAL INDICATORS.

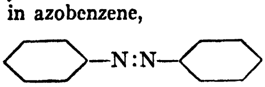
sulfite ($N_2S_2O_4$) is frequently used to reduce the dye to the leuco form.

Selected classes of dyes are discussed as follows:

(1) Azo- dyes, (2) Disazo- dyes, (3) Triphenylmethane dyes, (4) Xanthene dyes, (5) Acridine dyes, (6) Thiazine dyes, (7) Alizarin and Anthraquinone dyes, (8) Indigo dyes.

The azo- dyes contain one or more azo- groups (—N:N—) as in azobenzene,



They are formed mainly by diazotization (see **Diazo-Compounds**) of primary amines and coupling with:

1. An **amine,** in acid solution. Reaction slow, accumulation of acid may be prevented by gradual addition of sodium carbonate.
2. A **phenol,** in alkaline solution. Reaction rapid, accumulation of acid is prevented by presence of alkali.

Coupling takes place at the carbon para to $—NH_2$ and —OH (—ONa) group; if the para carbon is occupied by another group, then coupling takes place at the carbon ortho to $—NH_2$ and —OH(—ONa), not at the carbon meta to $—NH_2$ and —OH but beta-naphthol and beta-naphthylamine at carbon number 1, never at 3 or 4. Aminonaphthols in (a) acid solution, at carbon ortho to $—NH_2$ group, (b) alkaline solution, at carbon ortho to —OH(ONa) group. Diamines undergo only meta coupling.

Colors certified for use under the Food, Drugs and Cosmetics Act of 1938 (see U. S. Code: Acts of the 75th Congress, page 990) (a) in foods, drugs and cosmetics: green numbers 1 to 3, yellow numbers 1 to 6, red numbers 1 to 4 and 32, orange numbers 1 and 2, blue numbers 1 and 2; (b) in drugs and cosmetics taken internally: green numbers 4 to 8, yellow numbers 7 to 11, red numbers 5 to 31 and 33 to 39, orange numbers 3 to 17, brown number 1, blue numbers 4 to 9, violet numbers 1 and 2, black number 1; and (c) in externally applied drugs and cosmetics: green number 1, yellow numbers 1 to 6, red numbers 1 to 13, orange numbers 1 and 2, blue numbers 1 to 5, violet numbers 1 and 2, black number 1. In the year 1940 certificates were issued for 1,610,000 lbs. of colors in the (a) group, 292,000 lbs. in the (b) group, and 9600 lbs. in the (c) group.

Special applications of dyes have attained a position of great importance. Some of these applications and the dyes used are given below. Data given for various dyes that are used for such special purposes as coloring food, chemical analysis, biological investigation, and photographic sensitizing. There are special dyes for such materials as gasoline and synthetic resins.

CERTIFIED BIOLOGICAL STAINS

The following dyes are certified by the Commission on Standardization of Biological Stains.

Name of Stain	Application	Solubility grams per 100 ml.
Aniline blue, water soluble	Cytoplasm (acid)	
Bismarck brown Y		1.4
Brilliant cresyl blue		
Brilliant green		
Carmin.	Nuclear (basic)	
Congo red	Cytoplasm (acid)	
Cresyl violet		0.4
Crystal violet		1.7 (chloride)
Eosin, bluish		39.1 (Sodium salt)
Eosin, yellowish	Cytoplasm (acid) Blood	
Ethyl eosin		0.03 1.13% sol in alcohol (95% strength)
Fast green FCF		16.0
Fuchsin, acid	Cytoplasm (acid)	
Fuchsin, basic	Nuclear (basic) Bacterial	
Hematoxylin	Nuclear (basic)	
Indigo carmine		1.7
Janus green B		5.2
Jeuner's stain		
Light green S F, yellowish	Cytoplasm (acid)	20.4
Malachite green		
Martius yellow		4.6 (Sodium salt)
Methyl green	Nuclear (basic)	
Methyl orange		0.5 0.015 (acid)
Methyl violet		2.9
Methylene azure		
Methylene blue	Nuclear (basic) Vital Blood Bacterial	3.6 (chloride)
Methylene violet		
Neutral red	Cytoplasm (acid) Vital	5.6 (chloride)
Nile blue A		
Nigrosin		
Orange G	Cytoplasm (acid)	10.9
Orange II		11.4
Phloxine		50.9 (Sodium salt)
Pyronin		9
Rose bengal		36.3
Safranin O	Nuclear (basic)	5.5
Sudan III	Fat	Insol. 0.15% sol. in alcohol (95% strength)

Name of Stain	Application	Solubility grams per 100 ml.
Sudan IV	Fat	Insol. 0.09% sol. in alcohol (95% strength)
Tetrachrome stain (MacNeal)		
Thionin	Nuclear (basic)	0.25
Toluidine blue		3.8
Wright's stain		

PHOTOGRAPHIC SENSITIZERS

Eosin, erythrosin	For yellow-green
Pinaflavole, orthochrome T	For green
Pinachrome, pinaverdol, acridine orange	For orange
Ethyl red	For orange-red
Pinacyanole (6800), naphthocyanole (7500)	For red of wavelength (Angstrom units) specified
Kryptocyanine (8000), dicyanine (9000), neocyanine (10,000)	For infrared of wavelength (Angstrom units) specified

(R.K.S.)

DYNAMIC CHARACTERISTIC. This refers to the characteristics of a piece of equipment under actual operating conditions. As applied to vacuum **tubes** it designates the characteristics obtained when operating into a load with a varying or a-c signal present in the circuit. Static characteristics of such tubes are taken with fixed voltages, which are adjusted by steps, on the various electrodes. Examples of these are the mutual characteristic which gives the relation between grid voltage and plate current, and the plate characteristic which gives the relation between plate voltage and plate current. Often these characteristics do not begin to approach the behavior under regular operating conditions because of circuit impedances and varying voltages and currents present in the circuit. Fortunately, the dynamic characteristics may be obtained with sufficient accuracy from the static characteristics when the circuit constants have been given. The tube circuit may then be analyzed. (L.R.Q.)

DYNAMIC COOLING AND HEATING. Adiabatic Processes in the Atmosphere.

DYNAMIC METAMORPHISM. Metamorphism.

DYNAMIC PRESSURE, FLUID. The pressure necessary to accelerate a fluid from rest to a speed of V is the dynamic pressure equivalent to that speed. If ρ is taken as mass density of the fluid,

$$\text{Dynamic pressure, } q = \frac{\rho V^2}{2}.$$

This conception is useful in aerodynamics as the dynamic pressure represents the unit air pressure acting on a surface increment in atmospheric air moving with velocity V over the surface. By **Bernoulli's theorem,**

$$p = p_0 - \frac{\rho v^2}{2} = p_0 - q.$$

The vacuum caused by air in motion over a surface is greatest when this imaginary dynamic pressure is greatest since q represents the vacuum. (F.T.M.)

DYNAMICAL PARALLAX. Dynamical parallax is an indirect method for the determination of the distances of **binary stars.** In the determination of **orbits** of binary stars the semi-major axis of the relative ellipse is determined in angular units. This length cannot be expressed in any linear units unless the distance of the system is known. With this distance known the orbit may be solved, and the combined masses of the two stars determined in terms of the sun's mass as unity. For the systems thus far solved it is found that the majority of the stars are between 1/5 and 10 times the mass of the sun. Hence, as a first order of approximation we may assume that for any binary system the combined mass will not differ greatly from twice the mass of the sun.

The rigorous expression for the so-called harmonic **Keplerian Law of Planetary Motion** shows the period or revolution of one object about the other to be dependent upon the combined masses of the objects and also their distance apart. The combined mass of the earth and the sun is known, and the period of revolution of the earth about the sun is one year. Hence, assuming the combined mass of the binary system to be twice that of the sun, and knowing the period of revolution of the system in years, we may find the mean distance between the components of the system in astronomical units. Since from the orbit we know the distance between the components in angular units, we can immediately find the angular distance subtended by one astronomical unit at the distance of the star, or, in other words, we can find the stellar parallax of the system.

The parallax thus determined is based on the assumption that the combined mass is twice that of the sun. However, with the parallax thus computed and the apparent **magnitudes** of the stars known, we can then calculate the **absolute magnitude** of the system. With this absolute magnitude we go to the **mass-luminosity** relation and get a second approximation to the mass of the system. With this improved mass the process is repeated and an improved value of stellar parallax obtained. By a sufficient number of approximations, values of the so-called dynamical parallax may be obtained with an accuracy approaching that of the direct trigonometric determinations.

Within recent years several methods have been devised for obtaining dynamical parallaxes for systems which are moving so slowly that orbit determination is impossible. While such methods do not lead to results of great accuracy, nevertheless, they are valuable for statistical discussions. (W.K.G.)

DYNAMICS OF GASES. The laws pertaining to the forces of gas pressure and to the flow of gases are based ultimately upon the **kinetic theory,** but certain principles can be stated without analyzing their origin to that extent. To a first approximation, the **ideal gas law,** or the **Boyle-Charles law,** represents the dynamics of gases at rest. At a given temperature, the pressure of a body of gas varies inversely as its volume, and hence directly as its density (**Boyle's law**); and at a fixed volume, the pressure is a linear function of the temperature, varying at the same rate (1/273 per centigrade degree) for all gases (**Charles's law**). But dynamic processes in a gas are complicated by the fact that change in volume is in general accompanied by change in temperature, so that simple dynamics is overshadowed by **thermodynamics.** It was for this reason, for example, that the correct formula for the speed of **sound** in air proved, for a time, elusive. A gas is highly compressible, and this property affords ready opportunity for the energy of mechanical impulses, which would be merely transmitted by a non-compressible fluid, to be transformed into heat, or for the gas to use its thermal energy to create impulses of its own. The same circumstance complicates the effect of gravity. The **atmosphere** is not an ocean of uniform density and definite depth; its pressure and density are logarithmic functions of the altitude. The forces associated with moving gases form the subject-matter of **aerodynamics.** (See also **Ther-**

mal Convection, Winds, Pressure Gauges, Air Pumps, etc.) (L.D.W.)

DYNAMICS OF ROTATION. A body is said to rotate when all of its particles move in circles about a common axis with a common **angular velocity.** This motion may be either free or constrained, as illustrated, respectively, by the earth turning on its axis, and by a flywheel or a pendulum.

If one twirls an umbrella about its handle, it tends to open. This is because the **centrifugal forces** exert torques tending to throw the stays outward on their pivots. Through any point of a rigid body there are at least three lines, mutually perpendicular, about which the body would rotate without any such centrifugal torque. It may be shown that the **moment of inertia** of the body with respect to any one of these lines is either a maximum or a minimum as regards all lines through the given point. They are called principal axes. In general there is only one line about which a free body will rotate permanently; it is the principal axis of greatest moment of inertia through the **center of mass.** A body constrained to rotate about an arbitrary axis will, when released, tend to change its motion so as to rotate about this permanent axis, but the adjustment is complicated by precession, so that the body may "wobble" like a badly thrown discus.

If a free body, at rest, is given a sudden push along some line not through the center of mass, it begins to rotate about some other line beyond the center of mass and perpendicular to the applied force. This line is the axis of instantaneous rotation. It is only a temporary axis, the rotation being at once transferred to an axis through the center of mass. The line mutually perpendicular to the instantaneous axis and to the line of the force passes through the center of mass, and its intersections with the other two lines are conjugate points, having the same relation as the center of oscillation and the center of suspension of a rigid **pendulum.** If the push is given in line with the center of mass, the axis of instantaneous rotation is at infinity, and the motion is then one of pure translation.

A torque applied so as to tend to change the axis about which a body is rotating results in the peculiar behavior known as **precession.** The **angular momentum** of a rotating body is the product of its angular velocity by its moment of inertia about the axis of rotation. The **kinetic energy** associated with rotational motion is equal, in absolute units, to ½ the product of the moment of inertia by the square of the angular velocity—a formula analogous to that for kinetic energy of linear motion. (L.D.W.)

DYNAMITE. Explosives.

DYNAMO. Dynamo refers to a general class of machines capable of transformation of electrical into mechanical energy, or vice versa. The word is a shortened form of dynamo-electric. A feature of all dynamo machines is the employment of magnetic induction in effecting the transformation. The essential parts of an ordinary dynamo are the **armature** and the **field.** One of these is mounted on a rotating shaft, and the other is stationary. Theoretically, the dynamo is perfectly reversible, that is, it may be used either as a generator or a motor. Actually, this is not always possible. (See also **Generators, Motors.**) (F.T.M., L.R.Q.)

DYNAMOMETER. A dynamometer is an instrument for measuring force, such as a spring balance. Most writers, however, apply the term to certain devices for the measurement of mechanical power. The principal classification is derived from the fact that some types of dynamometers absorb all of the power, which is converted into heat, whereas others transmit the power they receive to some other absorber of power, measuring it during the process. These are called, respectively, absorption and transmission dynamometers.

In the absorption dynamometer class there are types which convert the mechanical to heat energy through the medium of mechanical friction. They are all similar to the Prony brake. (See **Brake Horsepower.**) The friction surfaces are variously wooden blocks against metal drums or pulleys, bands with wooden cleats, ropes, or friction-surfaced brake bands. Also there are hydraulic dynamometers which absorb the power by fluid friction. One common arrangement is similar to a **centrifugal pump,** except that the casing, instead of being rigidly fixed to a bed plate, is freely supported on the propeller shaft. It is restrained from rotating by an attached arm. The restraining moment in the brake arm is measured by platform or spring scales. The energy absorbed appears as a heating of the water in the dynamometer. To prevent it boiling it must be steadily renewed. Thus the energy is carried off in a stream of water entering the dynamometer cool and leaving warm. Air friction has also been set to use in the fan brake absorption dynamometers.

One of the most convenient means for measuring power is to convert it to electrical power (watts). In an electrical dynamometer a **generator** is slightly modified. The stator is mounted, free to revolve, but restrained from revolving by a brake arm which is attached to it, and to which are fastened weighing scales. The tendency of the casing to rotate with the rotor which is connected to the source of the power is opposed by the brake arm. The force shown on the scales becomes a **torque** when multiplied by its lever distance from the center of rotation. Since power is torque multiplied by rotative speed, the only other reading necessary from the dynamometer is the speed of the rotor shaft. In all absorption dynamometers the casing is mounted free to revolve under the action of mechanical friction, fluid friction, or magnetic drag. Actual rotation is prevented by the attached brake arm. Power is measured as a torque operating at the rotative speed of the driven shaft.

A transmission type dynamometer is illustrated by the torsion type, in which a shaft delivering power is twisted through a small angle by the torque. Such a shaft may be calibrated at rest by measuring the torsional deflection obtained under known torque loadings. This dynamometer has its greatest field of usefulness where the other types are impractical. Measurement of power output from a large marine engine is typical. (F.T.M.)

DYNAMOTOR. This is a double **armature** rotating electrical machine. One of the armatures is wound for low voltage direct current, and serves as a motor armature. The other armature is wound for a high d-c voltage and serves as a generator winding. The machine is used for supplying plate voltage to portable radio equipment, being operated from storage batteries on the motor end and supplying the high voltage d.c. from the generator winding. (L.R.Q.)

DYNATRON. This term is applied to a vacuum **tube** operated in such a manner that its plate characteristic has a negative resistance section, i.e., the plate current increases while the plate voltage decreases. The most common application is for stable **oscillators.** The screen-grid or tetrode vacuum tube exhibits this characteristic when the screen voltage is higher than the plate voltage. (L.R.Q.)

DYNE. The c.g.s. absolute unit of force, defined as the force required to give a free mass of one gram an acceleration of 1 cm. per sec. per sec. Since the weight of one gram mass, or one gram of force, would give it an acceleration of about 980 cm. per sec. per sec., a dyne is about 1/980 of this weight, or only a little more

than a milligram. Nevertheless it is a fundamental dynamic unit of physics, and is the basis of the units of **energy** (**erg**), of **power** (**watt**), of **pressure** (**bar**), etc. (L.D.W.)

DYSENTERY. A term applied to intestinal disorders characterized by frequent watery stools which may contain **blood, pus,** and mucus. Abdominal pain, tenesmus, and constitutional symptoms may accompany the diarrhea. Dysentery may be caused by **bacteria, parasites,** and chemical irritants. There are two important forms—amoebic and bacillary.

Bacillary dysentery is world wide in distribution, but occurs most commonly in tropical and subtropical climates. Lack of sanitation and crowding are predisposing factors. Flies are known to spread the disease. It is always a problem in armies and cases occurred on all fronts in World War I and II. The causative bacteria are varieties of *Bacillus dysenteriae—Shiga,* and the Flexner group, including Schmitz, Sonne, and the paradysenteriae are the commoner types. *B. dysenteriae Shiga* causes the most severe disease. Symptoms vary according to whether the disease is mild, fulminating, relapsing or chronic. The mild forms may be marked by diarrhea only. In more serious types, the onset may be sudden, with severe abdominal cramps and copious diarrhea. Fever, prostration, and dehydration may be extreme. **Arthritis, neuritis** and **endocarditis** may occur as late complications after the acute phase has passed. Chronic dysentery and healthy dysentery **carriers** occur.

The treatment of bacillary dysentery is with **sulfonamides,** sulfadiazine being the most effective at present. Sanitary disposal of feces, fly control, water, milk, and food inspection and personal cleanliness are all important in the control of the disease.

Amoebic dysentery is an infection of the large intestine caused by the protozoan, *Entameba histolytica.* Its geographical distribution is the same as that of bacillary dysentery. A common mode of spread is by carriers—healthy individuals who pass the **cysts** in their stools. Bloody diarrhea with relatively little pus is characteristic. The disease tends to be recurrent—many remissions and exacerbations occurring. It may be difficult to distinguish amoebic from bacillary dysentery in the acute stage, except by the detection of amoebic cysts in the stools of the patient with the amoebic form. Complications of amoebic dysentery are metastatic **abscesses,** usually in the liver, but other organs may be the site.

The treatment of the acute disease is with various drugs, chiefly carbarsone, an arsenical, and **emetine,** which is a specific in amoebic liver abscess. In intestinal amoebiasis, carbarsone and emetine are used frequently in courses, the one following the other. Chiniofon, an iodine compound, is also used. (D.M.H.)

DYSMENORRHEA. **Menstruation.**

DYSPAREUNIA. Painful or difficult **coitus.** (R.S.M.)

DYSPEPSIA. This term does not represent any disease entity, but is merely a group of symptoms due to various physiological or **pathological** activities of the **gastro-intestinal** tract which may indicate some form of impairment of the normal digestive function. (R.S.M.)

DYSPNOEA. Dyspnoea means difficult breathing. More specifically, the term indicates discomfort arising because of consciousness of the necessity to exert effort to breathe. This occurs normally after violent exercise, and is a frequent symptom of heart disease, **pneumonia,** and **emphysema;** any condition which is associated with **acidosis, oxygen** lack, or mechanical hindrance to the respiratory movements may cause dyspnoea. (D.M.H.)

DYSPROSIUM. Symbol: Dy. Atomic number: 66. Atomic weight: 162.46. (**Isotopes:** page 290.) Type of compound: Dy_2O_3, white. Color of salts: Yellow. Discovered by Boisbaudran in 1886. A member of the **yttrium** sub-group of the rare earth metals. (R.K.S.)

E

E LAYER. Ionosphere.

***e*, THE NUMBER.** The number e may be defined by:

$$e = \lim_{n \to \infty} \left(1 + \frac{1}{n}\right)^n,$$

or by

$$e = \lim_{x \to 0} (1 + x)^{1/x},$$

and is represented by the infinite series

$$e = 1 + \frac{1}{1!} + \frac{1}{2!} + \frac{1}{3!} + \frac{1}{4!} + \cdots + \frac{1}{n!} + \cdots$$

It has the approximate value: $e \approx 2.71828$.

The number e is an **irrational number** and is also a **transcendental number.** It is used as the base of the system of natural (or Napierian) **logarithms.** (L.L.S.)

EAGLE. Aves, Falconiformes. Large birds (**Aves**) of prey with strong hooked beaks, large curved claws, and powerful flight. The American golden eagle, *Aquila chrysaetus,* is an example of the typical members of the group, which also includes the harpy eagles, hawk eagles, harrier eagles, sea eagles, and others. The bald eagle, *Haliaeetus leucocephalus,* national bird of the United States, is one of the sea eagles. (A.W.L.)

EAR. Auditory Organ.

EARTH. (See tables of planetary data in the article on **Planet.**) The earth is third planet in point of distance from the sun and is unique in being the only planet which is known to carry an **atmosphere** capable of supporting human life.

The earth is approximately spherical but, due to the fact that it is rotating on an axis, the actual shape is an oblate **spheroid.** The actual shape is determined by making accurate determinations of astronomic **latitude** at a number of different stations and then determining the linear north-south distance between the two stations measured along the surface of the earth. If the earth were a perfect sphere, a degree of latitude would have the same linear length everywhere. Observations show that a degree of astronomic latitude is longer the higher the latitude on the earth. Accurate measurements indicate a difference of 26.70 miles between the equatorial and polar diameters of the earth, the polar being the shorter.

A theory that the earth is in rotation was advanced by Copernicus in the 15th century but it was not until the 19th century that any proofs independent of the motions of the heavenly bodies were available. The most familiar of these is the so-called **Foucault pendulum.**

In accordance with the Copernican Theory of the structure of the universe, the earth should be revolving about the sun, but a proof of this motion was not available until 1725, when Bradley demonstrated that the **aberration of light** which he had previously observed could only be explained by the revolution of the earth about the sun. There are several other proofs of the revolution of the earth, but none of them can be demonstrated without the use of refined telescopic observations. The best known of these proofs is the annual **variation in the radial velocities** of the stars and **stellar parallax.** (W.K.G.)

EARTH, ELECTRICAL. Ground, Electrical.

EARTH RADIATION. Heat Balance in the Atmosphere.

EARTHNUT OIL. Esters.

EARTHQUAKES. The lithosphere, or so-called crust of the earth, is continuously undergoing deformative movements which are expressed at the surface in folds, faults and volcanic activity. When the adjustments beneath the surface are sudden a vibration is expressed in the form of an earth tremor or earthquake, the result of a sudden fracture in the lithosphere.

An earth fracture is called by geologists a **fault,** and the surface along which realignment of the crustal blocks takes place is called a fault plane. The intersection of the fault plane with the surface of the earth is called the trace of the fault plane. The relative movement of the fault blocks may be vertical, horizontal or oblique. Pronounced vertical movements of the fault blocks may produce fault scarps, often the loci of intermittent earthquakes. Incipient fault scarps may be, however, obliterated or greatly reduced by erosion. Earth tremors which are too gentle to be recorded by the senses alone are called **microseisms.** Instruments for measuring earthquake waves are called **seismographs** or seismometers and the study of earthquakes is called **seismology.**

The first seismograph was used in Italy in 1841, but many different types of instruments have been invented since. In the simple type of instrument, as illustrated,

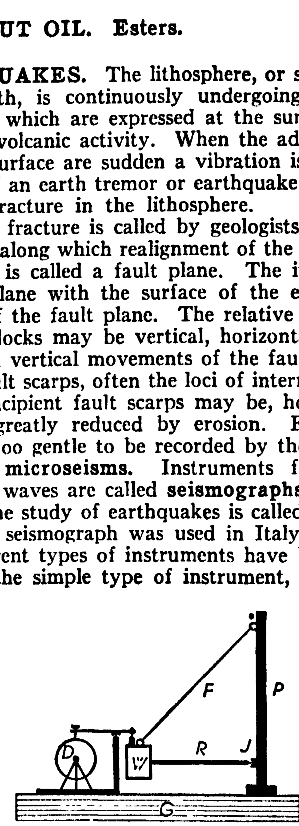


Diagram showing the principle of a seismograph. *G,* ground; *P,* post set in the ground; *W,* weight; *R,* rigid support contacting the post with a free-moving sharp point at *J*; *F,* flexible wire; *D,* recording drum revolved by clockwork; and the marker extends from *W* to *D.* When the ground shakes, the suspended weight, due to its inertia, scarcely moves, but the shaking motion is transmitted to the marker which leaves a record on the drum.

a delicately balanced horizontal pendulum is attached to a mast from the heavily weighted end. An arm attached to the pendulum magnifies and records the movements of the pendulum on a revolving drum or **chronograph** which automatically registers both the time and magnitude of the shock. The resulting records are called **seismograms.** A seismoscope is an instrument which detects an earthquake but does not record it. The various types of true seismographs may be classified as horizontal, vertical, inverted, electromagnetic, and torsional.

The principal machines now in use are the Milne-Shaw, McComb-Romberg, Wenner, Benioff, Wood-Anderson, Galitzin, Wiechert and Mainka. Of the American operating stations there are 46 in the United States, one in Puerto Rico, two in Alaska, and 6 in Hawaii. Many more are needed, and the same holds true of the rest of the world, especially on the oceanic islands.

The point of origin of an earthquake, at varying dis-

tances beneath the surface of the earth, is called the **centrum.** Directly above the centrum, on the surface of the earth, is the **epicentrum,** or center of the maximum shock.

Earthquake waves are classified as follows: 1. Preliminary. These waves pass through the earth following a curved path below the straight line from the earthquake (**epicenter**) to the recording instrument (**Seismograph**). There are two types of these waves, probably following the same path but at different velocities. The first preliminary wave, designated *P* for **primus,** is also known as (a) longitudinal, because of its back and forth vibration in direction of progress, and (b) compressional, because of its effect on the medium through which this type of wave passes. When these waves are reflected at the surface of the earth, or other reflecting surface, they are known as reflected waves. All of these waves are also known as body waves. 2. Surface waves or long waves. Much of the energy of an earthquake goes into surface or long waves. These are mainly of two types, (a) Rayleigh, with vibration in the form of a vertical ellipse back and forth in the direction of progress, and (b) Love, with only transverse-horizontal movement at right angles to the direction of progress.

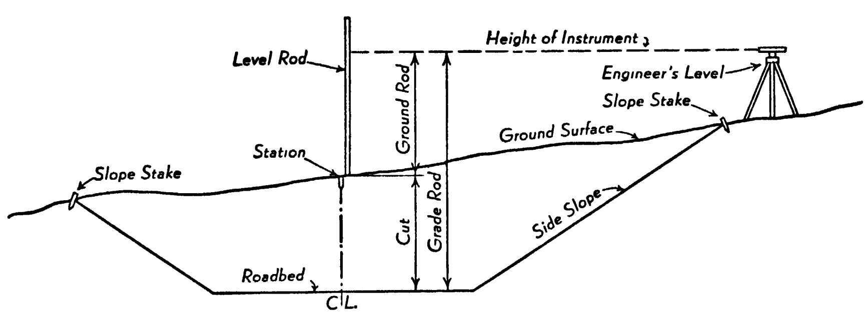
The intensity or destructive activity of an earthquake, in populated areas, is determined by the acceleration, amplitude, period of vibration, length of time of vibration, and character of the surficial materials in the region of the epicenter.

Amplitudes vary from a fraction of an inch to several inches. The destructive phase of earthquakes varies from 1 minute to only a few seconds. It is estimated that for the whole earth, there are over 10,000 earthquakes per year, but the majority of them occur in regions of recent mountain building. A major earthquake occurs, approximately, once a week. The total number of all earthquakes, with definite epicenters, was 548, between 1925 and 1930; one about every 16 hours.

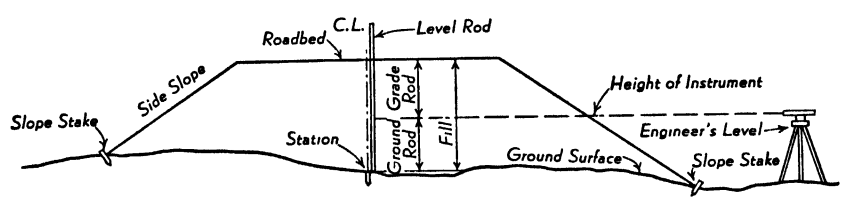
Dutch East Indies, Caribbean Sea, Mexico, South America, and Alaska. (R.M.F.)

EARTHWORK. This term includes work, the object of which is to alter the surface of the earth to serve some useful constructional purpose. In addition to excavation, building of embankments and trimming of slopes, earthwork also includes the clearing and grubbing of rough land, grading, etc. Excavation of rock and loose rock is usually considered earthwork. Among the most common forms of earthwork are preparation of subgrade for railways and highways, building of embankments for hydraulic work and construction of open drainage systems. In the preparation of a roadbed, the original surface of the ground is altered to the required degree by cuts and fills. As far as possible, cut should equal fill, so that the material excavated may be hauled a short distance and used to fill depressions in the proposed roadway. Where the amount of cut is insufficient for filling, the deficiency must be made up by hauling from **borrow pits.** An excess of cut is deposited on spoil banks.

The vertical dimension of the cut or fill at any **station** is found by leveling (see **Differential**). An engineer's **level** is set up near the station. The height of the instrument, which is the vertical distance between the line of sight of the level and a reference plane called the datum, is obtained by taking a rod reading (see **Level Rod**) on a **bench mark** or other point of known elevation above the datum. After the height of instrument is determined a rod reading is taken on the ground at the station. This is the ground rod. The difference between the height of instrument and the known **grade** elevation at the station is the grade rod The cut or fill is the algebraic difference between the grade rod and the ground rod. The point where the side slope of a cut or fill will intersect the ground surface is marked by a stake called a slope stake. Slope stakes are set before construction is begun.



Cross-Section of a Highway in Cut



Cross-Section of a Highway in Fill

It has been estimated that over 3 million people have been killed by earthquakes of intensities 9 and 10 from the 6th century to 1927. Tremors of the ocean bottom cause seismic seawaves, called *Tsunami* (Japanese term). Seismic seawaves have been known to rise 100′ or more, and when such waves break upon a densely inhabited coast, they cause great destruction of life and property. Approximately 224 seismic seawaves are known to have occurred, chiefly on the coasts of Japan,

To measure the amount of cut or fill in earthwork, transverse cross-sections of the cut or fill are measured at regular intervals. These sections are then plotted on paper, and the area computed. Sections are taken close enough so that the volume of earthwork between them is considered that of a prism of length equal to the distance between stations, and area equal to the average of the two sections. This is known as the end area method. A more accurate result is obtained by the use of the

prismoidal formula, which states that the volume of the earth equals $\frac{1}{6}(a_1 + 4a_m + a_2)D$, a_1 and a_2 are the end areas, a_m is the mid-section area, D is the length of the section being measured. Earthwork is usually done on a contract basis and paid for on the basis of volume excavated, or volume of fill. A fill of earth usually shrinks 10–20% upon compacting. Rock may be expected to occupy 15–30% greater volume after excavation than before.

If the volume of cut or fill between any two successive **stations** is given an algebraic sign (+ for cut and − for fill), the algebraic sum of the volumes starting at an initial station, may be represented by a continuous curve called a mass diagram. The abscissa for any point on the curve is its horizontal distance (in units of 100′) measured from the initial station; the ordinate is the algebraic sum (in cu. yds.) of the volumes up to the point. Plus-ordinates (cut) are plotted above the x-axis and minus-ordinates (fill) below. (F.T.M., C.W.C.)

EARTHWORM. Annelida, Oligochaeta. Terrestrial segmented **worms** of many species. They burrow in earth containing organic matter on which they live, coming to the surface only in damp cloudy weather and at night. Their activity in loosening and mixing the soil in fields is estimated to be valuable in crop production. (A.W.L.)

EARWIG. **Dermaptera.**

EBERHARD EFFECT. A photographic effect studied by Eberhard (1912). Eberhard gave a photographic plate a uniform exposure through a metal plate with openings of various sizes and found that the density of the exposed areas varied, the density decreasing with the size of the area. The amount of the variation in density increases with the thickness of the emulsion coating and is decreased by an exposure of the background or by general fog. The effect is produced by all organic developers but not by ferrous oxalate and is considered to be due to the effect of the accumulation of restraining by products of the process of development. The Eberhard effect is a factor affecting the fidelity of photographically recorded sound, and the accuracy of the photographic image in astrophysical and photometric investigations. (C.B.N.)

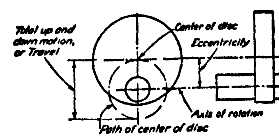
EBONY. **Diospyros Ebenum.**

EBULLITION. The boiling or ebullition of a liquid is due to the escape of bubbles of its vapor formed where heat is applied below the surface, as at the bottom of a kettle. For the bubbles to form, the temperature must be sufficient to produce a vapor pressure equal to the hydrostatic pressure of the liquid plus the pressure of the air or the vapor above it; hence at normal atmospheric pressure the liquid must be somewhat hotter than the normal **boiling point.** If the liquid contains a dissolved gas, the first bubbles to appear are composed largely of that gas; the transition from the escape of these bubbles to ebullition proper may not be marked. When the liquid has begun to boil steadily, it maintains a very nearly constant temperature until it has all boiled away, no matter how rapidly the heat is applied.

The formation of vapor bubbles appears to require some sort of nucleus; so that if the liquid is pure and perfectly free from suspended matter, and the vessel very smooth, the liquid may become superheated before ebullition suddenly begins. If the solid surface imparting heat to the liquid is very hot, a film of vapor forms between it and the liquid and escapes quietly from under the liquid without forming bubbles. This is the so-called "spheroidal state," observable when drops of water glide silently off a hot stove. (L.D.W.)

ECARDINES. **Brachiopoda.**

ECCENTRIC. The eccentric is a machine element employed to convert rotating to reciprocating motion. Its function is similar to that of the **crank.** The eccentric is used chiefly for short throws, where it would be undesirable to break the shaft, as is necessary in the case of a crank. It consists of a disk mounted on a shaft in such a way that the geometric center of the disk does not coincide with the center of rotation. The

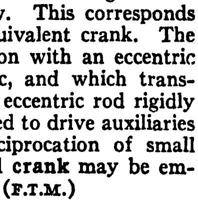


Simple eccentric.

distance between the center of rotation and the geometric center of the eccentric is the throw. This corresponds to the crank-arm distance of an equivalent crank. The eccentric must be used in conjunction with an eccentric strap which surrounds the eccentric, and which transmits the reciprocating motion to an eccentric rod rigidly attached. The eccentric is chiefly used to drive auxiliaries such as valve gear, and where reciprocation of small magnitude is needed. The **cam** and **crank** may be employed to provide similar motion. (F.T.M.)

ECCENTRICITY. This term is used in astronomy with two different significances. The term as descriptive of the shape of an **ellipse,** and hence as one of the elements of an **orbit,** is discussed elsewhere. We shall limit this article to a brief description of the correction for eccentricity that must be applied to many types of instruments used for **angular** measurement. Instruments for this purpose usually consist of a circle graduated in angular units, with an arm, assumed to be concentric with the circle, which sweeps around the circle, carrying a **vernier,** or a measuring microscope, for the purpose of determining accurately the direction of the arm relative to the circle. It is practically a mechanical impossibility to make the centers of the circle and the measuring arm exactly coincident.

In the diagram we have C the center of the circle OMA, graduated from O. C' is the center of the measuring arm (commonly known as the alidade). The direction $C'M$ is the actual direction of the alidade, while OM is the direction obtained from the circle reading (i.e., the angle OCM). The difference between these two directions, the angle $C'MC$, is the eccentricity correction for the circle reading OM. This will be different for different circle readings, being zero for the circle reading OA.



Eccentricity correction for circle with alidade.

An equation may be developed which will give the eccentricity correction for any circle reading as a function of the reading and three numerical constants. To determine these constants at least three known angles must be measured with the instrument. The differences between the values obtained with the instrument and the known values of the angles are the eccentricity corrections for the circle readings. These eccentricity corrections are then used for the solution of three equations for the three constants. With the constants determined the equation, giving the eccentricity correction for any circle reading, may be written down. The results are usually tabulated, or plotted on a curve and supplied by the maker of the instrument. (W.K.G.)

ECCENTRICITY OF A CONIC. **Conic Sections.**

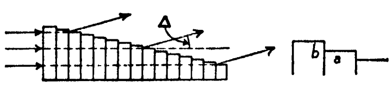
ECDYSIS. The molting or shedding of the **cuticula** by **arthropods.**

Since the cuticula of these animals is also the rigid skeletal support of the body and is inelastic, it is shed at intervals during growth and a new covering of larger dimensions is formed. In preparation for molting the insect or other arthropod becomes inactive for a time, then by crawling movements crowds forward in the old integument, which splits down the back and allows the animal to emerge. During the resting period preparation is made by the secretion of fluid from the molting glands of the cellular layer and the loosening of the under part of the **cuticula.** Following the shedding of the old cuticula, a new layer is secreted during a further period of inactivity. All cuticular structures are shed at ecdysis, including the terminal linings of the alimentary tract and of the air tubes if they are present.

The **molting** of reptiles is sometimes called ecdysis. (A.W.L.)

ECHELETTE. **Echelon.**

ECHELON. A highly specialized form of **diffraction grating,** devised by Michelson. It consists of a row of glass plates of exactly equal thickness, packed together to form a miniature stairway of equal risers. The light enters normally to the largest plate at one end (see figure) and emerges at various deviations through



the low "risers." It is easily shown that if the thickness of the plates is a, the height of the "risers" b, and the refractive index of the glass n, the equivalent path difference between successive emergent streams for any angle of deviation Δ is $na - a\cos\Delta + b\sin\Delta$; or since Δ is in practice always small, $\cos\Delta = 1$ and $\sin\Delta = \Delta$ (in radians), giving $(n-1)a + b\Delta$. This must be equal to an integral multiple, N, of the wavelength λ for any spectrum line, the deviation of which is therefore

$$\Delta = N\frac{\lambda}{b} - (n-1)\frac{a}{b}.$$

The smallest value N can have (for $\Delta = 0$) is $(n-1)\frac{a}{\lambda}$, which, since a is usually several mm. and $(n-1)$ is 0.5 or more, is of the order of several thousand. The **dispersion,** viz.,

$$D = \frac{d\Delta}{d\lambda} = \frac{N}{b} - \frac{a}{b}\frac{dn}{d\lambda},$$

is correspondingly large. The echelon is thus especially adapted to the study of the **hyperfine structure** of spectrum lines.

A kind of reflection echelon of very small steps, called an "echelette," has been ruled on metal by R. W. Wood. (L.D.W.)

ECHIDNA. Mammalia, Monotremata. The spiny ant-eaters of the Australian region. Egg-laying mammals from 1′ to 20″ in length, belonging to several species. The body is covered with hair and spines and has a slender snout, short legs, and strong claws. They are burrowing animals. There are two genera, *Tachyglossus* (*Echidna*) and *Zaglossus* (*Proechidna*). (See also **Fossil Mammals.**) (A.W.L.)

ECHINODERA. **Kinorhyncha.**

ECHINODERMATA. A large division of the animal kingdom including the starfishes, sea cucumbers, brittle stars, sea lilies, sea urchins, and basket stars, all marine animals.

This phylum is characterized by the following structures: 1. The adult is almost perfectly radially symmetrical, although the young are bilateral. 2. The wall of the body contains a hard skeleton in most forms, made up of calcareous bodies called ossicles. 3. The **coelom** is well developed. 4. A water vascular system is present, consisting of a closed series of tubes opening to the exterior at one point on the body and bearing many delicate sacs, the tube feet or tentacles, which protrude at the surface of the body. 5. There is no special excretory system.

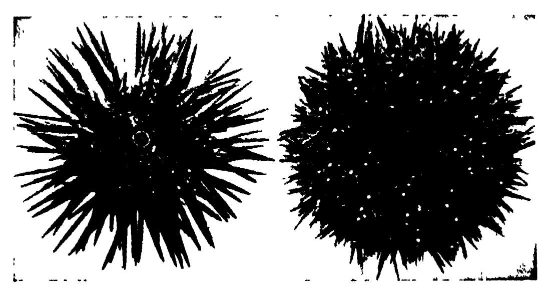
The echinoderms are divided into several classes which fall into two subphyla:

Subphylum Eleutherozoa. Without a stalk.
- Class **Asteroidea.** The starfishes.
- Class **Ophiuroidea.** The brittle stars.
- Class **Echinoidea.** The sea urchins, sand dollars, etc.
- Class **Holothuroidea.** The sea cucumbers.

Subphylum Pelmatozoa. With a stalk at least when young.
- Class **Crinoidea.** The feather stars, basket stars, and sea lilies.

(See also **Invertebrate Paleontology.**) (A.W.L.)

ECHINOIDEA. The sea urchins, keyhole urchins, and sand dollars. A class of the phylum **Echinodermata.**



Echinoidea. (*N. Y. Zoological Society.*)

The members of this class are distinguished by the following characters: 1. The body is circular, varying from almost globular to thin disks. 2. The tube feet are suckers. 3. The surface bears long spines and **pedicellariae.** 4. There are no radiating arms. 5. The ossicles are closely associated to form a shell.

Sea urchins live on organic matter of all kinds, including small animals, plant tissues, and waste matter They are of little economic importance but in some of the Mediterranean countries and to a limited extent in the Orient they are used as food.

The class is divided into the following orders:

- Order Cidaroida. Sea urchins without gills around the mouth.
- Order Centrechinoida. Gills present around the mouth.
- Order Exocycloida. With indications of bilateral symmetry.

Many species flattened. Sand dollars, etc. (A.W.L.)

ECHINORHYNCHOIDEA. **Acanthocephala.**

ECHIURIDA, ECHIUROIDEA. **Gephyrea.**

ECHO SUPPRESSOR. When an electric wave on a line encounters a discontinuity or point at which the impedances do not match (see **Impedance Matching**) some of it is reflected. This reflected wave may return to the sending end of the line with sufficient

amplitude to be objectionable. This is especially true in telephone service. While an effort is made to prevent reflections, there are cases where energy is fed back along the line and returns to the sender as an echo. In certain systems two lines (4 wires) are employed for transmission in the two directions and in such systems echo suppressors may be used to suppress the returning wave. This is accomplished by using a relay to short one line when there is a signal on the other. Thus if party A is talking and sending a voice signal to B, the voice currents on the line from A to B operate a shorting relay across the line from B to A so party A does not receive his own voice as an echo. (L.R.Q.)

ECLAMPSIA. A disease marked by convulsions during the latter half of pregnancy. (See **Toxemias of Pregnancy.**) (R.S.M.)

ECLIPSES. The term eclipse is applied to the darkening of a heavenly body due to the presence of another object. There are two cases to be considered, depending upon whether the object in question is self-luminous or is shining by reflected light. In the case of a self-luminous object, an eclipse or **occultation** takes place when an opaque object passes between the object and the observer. An object which is shining by reflected light is eclipsed when an opaque body passes between the object under consideration and its source of light. Eclipses of the first type are illustrated by an eclipse of the sun where the moon passes between the sun and the observer, in the case of an occultation of a star by the **moon,** and in the cases of **eclipsing binary** stars. A typical example of the second case is found in an eclipse of the moon where the earth passes between the sun and the moon.

Eclipses of the sun and moon have always been regarded with much superstitious awe and we find references to them in all of the ancient literatures. Because of their comparatively infrequent occurrence at any one point of the earth, records of eclipses of the sun may be used by historians to fix accurate dates for events. As an example of this reference may be made to an Assyrian tablet which states: "Insurrection in the city of Assur. In the month of Sivan the sun was eclipsed." This undoubtedly refers to the solar eclipse of June 15, 163 B.C. This is the same eclipse referred to in Amos VII, 9: "I will cause the sun to go down at noon, and I will darken the earth in the clear day."

The accompanying figure illustrates the shadow cast by the opaque body O; the body S being assumed luminous. An observer in the region A, the umbra

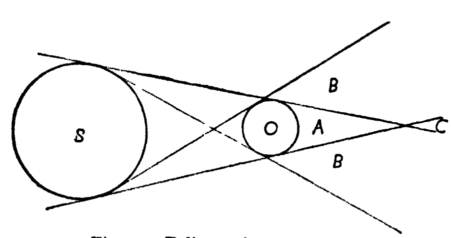


Fig. 1. Eclipse of sun or moon.

of the shadow, will be unable to see any portion of S and will be in darkness; in B and C, the penumbra, he will be able to see portions of S, in B observing the disk of S with a circular segment cut out, and in C observing S as an **annulus,** i.e., a ring of light. From a knowledge of the diameters of S and O and the distance between the two objects, the dimensions of the various parts of the shadow may be calculated.

For an eclipse of the sun we consider S (Fig. 1) as the sun and O the moon. Because of the fact that the **orbit** of the earth-moon system about the sun is eccentric the length of the umbra cone, A, varies between 236,000 miles at **aphelion** and 228,000 miles at **perihelion,** while, owing to the eccentricity of the moon's orbit, the distance of the moon from the surface of the earth varies between 217,800 miles at perigee and 247,500 miles at apogee. Examination of these numbers indicates that with the earth at aphelion and the moon at perigee, the surface of the earth will be 18,200 miles inside of the apex of the umbra. Under these conditions, the most favorable for an eclipse of the sun, the shadow of the moon on the earth will be a spot about 170 miles in diameter and within this area a total eclipse of the sun may be observed. Surrounding the spot of totality there will be a region of about 3000 miles radius within which the sun will be partially eclipsed. With the earth at perihelion and the moon at apogee the surface of the earth will be 19,500 miles beyond the apex of the umbra cone and, while an annular eclipse may be observed, no totality is possible.

As the moon revolves about the earth in its orbit the shadow sweeps along the plane of the moon's orbit with a velocity of about 2100 m.p.h. to the eastward. The earth is rotating at such a rate that a point on the **equator** is moving to the east with a velocity of about 1040 m.p.h. Accordingly under the most favorable conditions for a solar eclipse (i.e., the earth at aphelion, the moon at perigee, and the eclipse taking place at noon for an observer on the equator) the shadow will pass the observer with a speed of $2100 - 1040 = 1060$ m p.h. from west to east. The spot will pass the observer in slightly less than 8 minutes, which is the maximum duration of totality. The duration of a partial eclipse may be several hours.

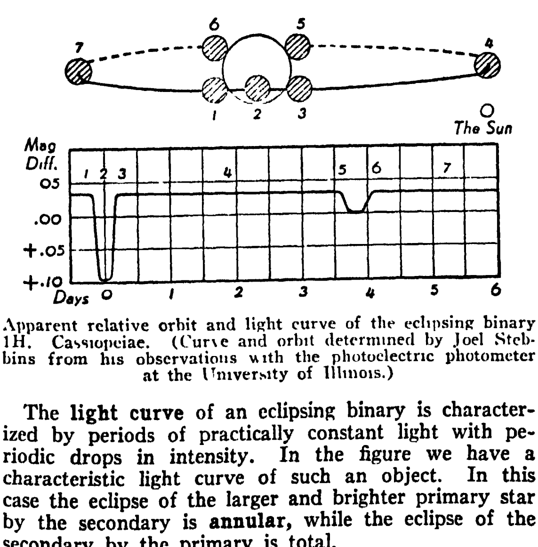
For an eclipse of the moon we consider S, Fig. 1, the sun and O the earth. From the relative dimensions and distances we find that even under the most unfavorable conditions, i.e., with the earth at perihelion and the moon at apogee, the shadow of the umbra cone of the earth will extend well out beyond the distance of the moon. Hence an annular eclipse of the moon is impossible although partial eclipses, i.e., eclipses when the moon passes through the earth's shadow far enough off the central line to pass outside the umbra, are quite common.

Because of the fact that the plane of the moon's orbit is inclined to the plane of the **ecliptic,** an eclipse of either the sun or the moon may occur only when the moon is close to one of the **nodes,** i.e., close to the plane of the ecliptic, and must also be in **conjunction** (for an eclipse of the sun) or in opposition (for an eclipse of the moon). Hence eclipses of the sun occur with the moon in new **phase,** and eclipses of the moon with the moon in full phase. Since the earth-moon system revolves about the sun once each year the line of nodes would pass through the sun twice in each year if the direction of that line were fixed in space. However, due to a **perturbation** known as regression of the moon's node, the line actually passes close to the sun three times each year. The period when the line of nodes is close to the sun is known as an eclipse season. Two solar eclipses, either total or partial, must occur each year, and five may take place. No lunar eclipse need occur in any year, although three are possible. The minimum number of eclipses in any year is two, both solar, while the maximum number is seven, five of the sun and two of the moon, or four of the sun and three of the moon. Considering the earth as a whole, solar eclipses are more common than eclipses of the moon. However, since each eclipse of the moon is visible over a large portion of the earth's surface while eclipses of the sun are observed only over very restricted areas, for any particular locality eclipses of the moon are more common than eclipses of the sun. The sequence of eclipses may be determined by an ancient method known as the **Saros.**

The progress of an eclipse of the sun is designated by a series of "contacts": first contact coming when the edge of the penumbra *B* first touches the sun, second contact when the sun first passes into the umbra *A*, third contact when the umbra leaves the sun, and fourth contact when the last edge of the penumbra leaves the sun. Accurate recording of the times of the contacts gives valuable information regarding the complicated motions of the moon.

For many years the only information regarding solar **prominences**, the **flash spectrum, Baily's beads,** and the **solar corona** that was available was obtained from observations taken at the time of total solar eclipses. At the present time the prominences may be carefully and completely studied at any time by means of the **spectroheliograph** and related instruments. An instrument has already been developed which will permit photography of the inner corona without an eclipse, and the instrument is still in the process of improvement toward the photography of the entire corona. However there are still several problems, e.g., the flash spectrum, which can only be obtained at the time of a solar eclipse and expeditions will probably be dispatched to regions of totality for many years to come. An eclipse of the moon is of comparatively little scientific importance. At the time of such an eclipse the moon is not completely dark, but is illuminated by light which is refracted into the umbra by the atmosphere of the earth, and the moon is visible with a dull reddish light. (W.K.G.)

ECLIPSING BINARY. When the **orbit** plane of a **binary star** lies so nearly in the line of sight of the observer that the components undergo mutual **eclipses** the object is known as an eclipsing binary. In case the binary is also a **spectroscopic binary** and the **parallax** of the system is known we have one of the most valuable specimens for stellar analysis. Eclipsing binaries are **variable stars,** not because the light of the individual components vary, but because of the eclipses. The most notable of the eclipsing binaries is the star **Algol** (β **Persei**), so named the "demon star" by the Arabs in all probability because they noticed the variation in light.



Apparent relative orbit and light curve of the eclipsing binary 1H. Cassiopeiae. (Curve and orbit determined by Joel Stebbins from his observations with the photoelectric photometer at the University of Illinois.)

The **light curve** of an eclipsing binary is characterized by periods of practically constant light with periodic drops in intensity. In the figure we have a characteristic light curve of such an object. In this case the eclipse of the larger and brighter primary star by the secondary is **annular,** while the eclipse of the secondary by the primary is total.

The **orbit** of an eclipsing binary may be determined from a study of the light curve. In addition to the seven **elements** of the orbit it is also possible to determine the relative sizes of the individual stars in terms of the radius of the orbit. In the determination of the orbit of a spectroscopic binary it is impossible to determine the semimajor axis, *a*, and the inclination of the orbit plane, *i*, independently; but a quantity ($a \sin i$), expressed directly in linear units (i.e., miles or kilometers) may be determined. If a star is both an eclipsing and spectroscopic binary we can determine all seven elements of the orbit, including *a* and *i*, in angular units from the light curve, and the quantity ($a \sin i$) in linear units from the spectroscopic data. Hence, we can determine the radius of the orbit in linear units and then get the sizes of the individual stars in linear units. Since from the period we can get the relative masses of the two stars, and can get the relative sizes from the combination of the photometric and spectroscopic orbits, we are able to determine the densities of the individual stars. (W.K.G.)

ECLIPTIC. The great circle cut out on the **celestial sphere** by the plane containing the **orbit** of the earth is known as the ecliptic. The ecliptic is the fundamental plane for the system of **spherical coordinates** in which celestial **latitude** and **longitude** are measured. The ecliptic is also the reference plane to which the planes of the orbits of all the **members** of the **solar system** are referred.

The plane of the ecliptic is inclined to the plane of the **equator** by an angle of approximately $23^\circ.5$, known as the obliquity of the ecliptic. The two planes intersect in a line known as the line of **nodes.** The points where this line of nodes intersects the celestial sphere are known as the **equinoxes.** The apparent motion of the sun in the ecliptic about the earth, due to the actual motion of the earth in its orbit, causes the sun to pass through each one of the equinoxes once each year. The point where the sun crosses the equator from south to north is known as the **vernal equinox,** and the opposite extremity of the line of nodes is the autumnal equinox. Due to **precession** the direction of the line of nodes is continually changing relative to the stars. At present the vernal equinox is in the **constellation** of **Pisces** and is continually moving along the ecliptic in a direction contrary to the annual motion of the sun at such a rate that it will complete one revolution of the ecliptic in approximately 25,000 years. (W.K.G.)

ECLOGITE. This is a coarse, granular rock composed chiefly of **garnet** and **pyroxene** with subordinate amounts of various minerals such as **rutile, magnetite, apatite,** etc. **Hornblende** sometimes is present, replacing the pyroxene, often to the extent that a garnet **amphibolite** is produced. The origin of eclogites is obscure, they may result in part from the deep-seated **metamorphism** of **gabbroic** rocks, but some may have resulted from crystallization of a primary **basic magma** under conditions of great pressure. They may represent segregations in a highly basic magma analogous to segregations of basic minerals in **granites** and other common **igneous** rocks. Seemingly confirmatory evidence of this idea is found in the chunks of eclogite-like material found in the **kimberlite** of South Africa. (E.S.C.S.)

ECOLOGY. The biological science that deals with the relations of organisms and the environment, including relations with other organisms. The relations of the individual are the subject matter of **autecology** and those of groups belong to **synecology.** In all of its divisions the science is now complex.

The living organism is inevitably exposed to certain physical factors which vary over the surface of the earth. The force of gravity causes stresses in its body and influences the pressure under which it must live. It is immersed in a fluid medium, either water or air, whose pressure on a given unit of surface depends on the amount of material above and so upon the altitude at which the organism lives. The pressure of water in the ocean is roughly one ton per sq. in. per

mile of depth. That of air is approximately 15 lbs. per sq. in. at sea level and lessens rapidly at higher altitudes. The oxygen content of these media influences respiration and their physical characteristics are important in locomotion. Many animals float and swim in water but relatively few fly and none can float permanently in the air. On the ground the friction between the body and the earth necessitates other types of locomotion and burrowing forms also must be specially adapted.

The temperatures to which the animal is subjected are extremely important, since they affect its physiological processes directly. The adaptation of animals to temperatures is often complex.

Light is important both for its effects on the living substance and as a factor in vision.

Since water is an essential constituent of living matter, the presence of an adequate supply is of fundamental importance to living things. On land variation is extreme. Between the dearth of water in arid regions and its abundance in marshes, and between the rainy and dry seasons of some areas, many factors interact in maintaining a supply which is sufficient only for animals that are adapted to conserve it. Even in such regions occasional years of drought impose severe conditions.

The food supply, like water, is a fundamental need. Since animals depend upon organic food this relationship is essentially one of living things with each other.

As a result of all of these factors, animals are restricted to parts of the earth where tolerable conditions prevail. Any species is found in its characteristic environment where it is associated with others that require similar conditions. These groups form the communities of the ecologist. By common agreement four main types are recognized: land communities, communities of waters and shores, communities of the seashore, and fresh-water communities. Land communities are those of deciduous forests, evergreen forests, grasslands, deserts, arctic and alpine regions, and minor subdivisions. In the sea are found the pelagic communities of the open waters, benthonic communities of the bottom, and littoral or shore communities, and in fresh water similar subdivisions are recognized in addition to those of still and running water.

Some of the major results of the adjustment of animals to the environment are expressed under **distribution.** (A.W.L.)

ECONOMIZER. Any device, the presence of which in a machine or cycle of machinery is nonessential, but which effects a saving, usually of the raw material, may be, with reason, named an economizer. Thus an attachment for the carburetor of a gasoline engine, designed to increase the energy delivered per unit of fuel used, may be called an economizer.

The economizer of a steam power plant is a heat exchange surface the purpose of which is to recover waste heat in the flue gas by absorbing it in the boiler feed water. Such economizers often form an integral part of the **boiler** surface, with heating surface in the form of tubes. Heat is recovered from flue gas by passing it through the tube surface into the feed water stream, which circulates inside the tubes. Ordinarily, no steam is produced in the economizer, though steaming economizers have occasionally been built. (F.T.M.)

ECTOCYST. **Zooecium.**

ECTODERM. **Germ Layers.**

ECTONEURAL SYSTEM. A portion of the nervous system of **echinoderms** which forms a plexus under the ectoderm and a radial nerve along each arm or equivalent radius. (A.W.L.)

ECTOPROCTA. A class including most members of the phylum **Bryozoa.** The included species live in colonies of many forms and are characterized by the retractile tentacles and by the anus lying outside of the circlet of tentacles.

The class is divided into two orders:

Order Gymnolaemata. **Lophophore** circular. Mouth usually closed by a flap called the operculum. Marine.

Order Phylactolaemata. Lophophore horseshoe-shaped or oval. Fresh-water species. (A.W.L.)

ECZEMA. A loose term indicating any inflammatory skin disease characterized by watery discharge with formation of scales and crusts. The term covers many skin diseases, but is used most commonly to describe the allergic dermatitis of infants and children. (R.S.M.)

EDEMA. Swelling due to excessive tissue fluids. The causes of edema are many. Physiologically the balance of the body fluids between the cells (intracellular fluid) the fluid bathing the cells (extracellular fluid), and the **blood** plasma is upset. Fluid is drawn from the blood into the tissues when there is a higher osmotic pressure in the tissues than in the blood (see **Osmosis**). This higher pressure may be due to an actual increase (e.g., in salt retention due to impaired kidney function) or it may be a relative increase, as in edema associated with low serum proteins in the blood due to nutritional deficiency. Obstruction to venous or lymph flow also results in edema, by the mechanical factor of increased pressure in the capillaries. This occurs with **varicose veins** and **elephantiasis.** Capillary damage due to infection, bacterial toxins, or to trauma will allow the passage of fluid from the blood into the tissue spaces and produce edema. Exudation of fluid into the extracellular spaces is part of the general process of **inflammation** and is found at the site of any localized inflammatory reaction or infection.

The common conditions characterized by edema are congestive **heart failure, nephritis, varicose veins, cirrhosis,** and allergic phenomena such as **angioneurotic edema.** In congestive failure, the fluid tends to collect in dependent portions, the feet, legs, and over the sacrum. In nephritis these areas plus the loose tissue around the eyes and other easily distensible tissues become edematous. If the edema is so marked that it involves all the tissues, the condition is spoken of as anasarca. (D.M.H.)

EDENTATA. **Ant-eaters, sloths and armadillos.** An order of mammals without teeth in the front part of the jaws and with no enamel on the teeth. The feet bear claws. (A.W.L.)

EEL. Pisces, Teleostei. Elongate slender fishes (**Pisces**) without pelvic fins and in some species lacking pectoral or median fins. Several families, including the true eels (*Anguilla*), the muraenas (*Muraena*), and the **conger eels** (*Leptocephalus*). The true eels are both marine and fresh-water animals and the muraenas and conger eels are marine. The muraenas are also called morays in some places. They are found in the warmer seas, especially about coral reefs.

Eels are eaten but they do not rank among the important food fishes. (A.W.L.)

EEL GRASS. ***Zosterna marina.*** Najadaceae. Eel grass is a common plant of sandy or muddy ocean shores. The plant has a creeping somewhat fleshy stem which roots freely at the nodes and has short erect branches. Usually it grows in salt water from a foot to over 4′ deep, and is frequently found in tidal pools. The long linear leaves have sheathing bases and float more or less erect in the water. The very peculiar flowers consist of a single **carpel,** containing a single **ovule,** two flat **stigmas,** and a **stamen,** which has two half **anthers** joined by a slender connective. These flowers are borne on a long flat **spadix.** The pollen

grains are thread-like and have a specific gravity equal to that of the salt water in which they grow. Thus when mature they float in the water, neither rising nor falling, as they are carried by the currents to the large flat stigma. The fruit is an **achene.**

Quantities of eel grass are raked up and dried. It is used for packing, for stuffing for various objects, in the manufacture of certain kinds of wall board and for insulation in walls.

The plants suffer periodically from a certain disease which seriously depletes their numbers. In some regions the natural growth of eel grass has been practically wiped out by this disease.

Fresh water eel grass, **Vallisneria spiralis,** is an entirely different plant, with an interesting method of **pollination.** (R.M.W.)

EELWORM. Nemathelminthes, Nematoda. A roundworm, *Ascaris lumbricoides,* 6–15″ long, parasitic in the adult stage in the small intestine of man and the domestic animals and during development in other tissues of the body. They sometimes occur in large numbers in children, who take in the young **larvae** in water or on raw foods, such as fruits and vegetables. (A.W.L.)

EFFECTIVE HEIGHT. Antenna.

EFFECTIVE RESISTANCE. Resistance.

EFFICIENCY. The general significance of this term as applied to a device or machine may be expressed as the ratio of output to input of energy or of power. If a d-c motor, for example, is operating on 4 amperes at 100 volts (the power input is 400 watts), and if the motor actually delivers only 280 watts of mechanical power, its efficiency at that load is 280 watts ÷ 400 watts, or 70 per cent. In general, the efficiency of a machine varies somewhat with the conditions under which it operates. Usually there is a load for which the efficiency is a maximum. This may be illustrated by a heavy block-and-tackle. For a small load the efficiency would be very low, because of power wasted in bending the ropes; for an excessive load it would again be low, on account of the large friction which would then develop; while for intermediate loads, higher efficiencies would prevail.

The concept may be extended to other than purely mechanical systems. Thus, the efficiency of an electric lamp may be expressed in candles or lumens of luminous flux (output) per watt of electric power (input); or that of an automobile horn in watts of acoustic power (noise) per watt of electric input. Various types of heat engine exhibit different thermodynamic efficiencies, i.e., the ratio of the work derived in the engine to the heat energy applied to it. (See **Thermal Efficiency.**) (L.D.W.)

EFFICIENT STATISTIC. Among **consistent statistics,** a **statistic** is said to be efficient if in large **samples** it is **normally distributed** with a minimum **variance.** Thus, an efficient statistic T_1 must first of all be consistent, secondly it must be normally distributed in large samples, and finally variance of $T_1 \leqq$ variance of T_2 in large samples, where T_2 is any other consistent statistic. There may be more than one efficient statistic but as the size of the sample increases, efficient statistics give essentially the same results since their variances approach equality. We state some properties of efficient statistics. If T_1 and T_2 are both efficient statistics of the parameter θ, and if the distribution of $(T_1 + T_2)\sqrt{N}$ approaches normality in the limit as N increases, then $\lim_{N \to \infty} r_{T_1T_2} = 1$, where r is the **coefficient of correlation between T_1 and T_2.** Let T_1 be an efficient statistic, and T_2 denote a consistent statistic which is not efficient such that

$$\lim_{N \to \infty} \frac{\sigma^2 T_1}{\sigma^2 T_2} = E < 1, \quad \text{then } r_{T_1T_2} = \sqrt{E}.$$

A **sufficient** statistic T which is consistent and normally distributed in the limit as N becomes large, is an efficient statistic. Clearly, in large samples, efficient statistics should be used wherever possible. (L.A.A.)

EFFLORESCENCE AND LOSS OF WATER. When a substance evolves moisture upon exposure to the **atmosphere,** the substance is said to be efflorescent, and the phenomenon is known as efflorescence. At ordinary temperatures the vapor pressure of water is as follows:

Temperature, °C.	Water Vapor Pressure, in mm. Mercury	
	At Saturation	At 50% Humidity
0	4.6	2 3
10	9.2	4 6
20	17.5	8 8
30	31 8	15 9
40	55 3	27.7

If the substance has a higher water vapor pressure than corresponds to that of the atmosphere at the given temperature, water vapor is evolved from the substance until the water vapor pressure of the substance equals the water vapor pressure of the surrounding atmosphere.

Substances that are ordinarily efflorescent are **sodium** sulfate decahydrate, **sodium** carbonate decahydrate. **magnesium** sulfate heptahydrate, **ferrous** sulfate heptahydrate.

When the saturated solution of a substance in water has a water vapor pressure greater than that of the surrounding atmosphere, evaporation of the solution takes place, leaving the substance.

See **Deliquescence** for the converse phenomenon. (R.K.S.)

EFFLUENT STREAM. A stream that flows out of another stream or out of a lake. Also a stream whose upper surface is below the surface of the local **ground water table.** (R.M.F.)

EFFUSIVE. The term applied by geologists to molten material (lava) which has been poured out on the surface of the earth from a vent or fissure, as distinguished from ejected volcanic material (ashes and bombs) and injected **magmas** (plutonic rocks). (R.M.F.)

EGG. The female reproductive cell or **gamete.**

EGGPLANT. Potato Family.

EGRET. Heron.

EIDER. Aves, Anseriformes. *Somateria.* **Ducks** of several species which breed in the far north along rocky coasts. They are noted for the fine down with which they line their nests. This material has a high commercial value and is collected for market. (A.W.L.)

EINSTEIN EQUIVALENCE PRINCIPLE. One of the interesting features of the theory of general **relativity** emphasizes the fact that the weights of bodies and the **forces** which they oppose to **acceleration** are proportional, each being in direct ratio to the masses of the bodies. The relativity theory points out that they are really indistinguishable. Everyone is familiar with the sensations of increased or reduced weight caused by upward or downward acceleration in a passenger elevator. If the elevator moved without noise or jar and if one could not see out, an accelerated

motion in any direction would occasion forces which one would be unable to distinguish from that due to a gravitational field. A cream separator or a centrifuge, or a bucket of water whirled about the head without spilling it, illustrate how **centrifugal force** (also due to inertia) may imitate gravity. It is this relationship which is enlarged upon in relativity theory as the principle of equivalence. (L.D.W.)

EINSTEIN SHIFT. According to the **relativity** theory, when radiation quanta leave a massive source like the sun or a **star**, they are retarded by the gravitational attraction and hence lose energy. This means that they lose **frequency** and that the wavelength λ increases. For a star of radius R and mass M, the fractional increase in wavelength is

$$\frac{\Delta\lambda}{\lambda} = \frac{G}{c^2} \cdot \frac{M}{R},$$

in which G is the **gravitation constant** and c is the **electromagnetic constant** (speed of light). The coefficient $G/c^2 = 7.414 \times 10^{-29}$ cm. per gram. For the sun, $M = 2.3 \times 10^{33}$ grams and $R = 1.394 \times 10^{11}$ cm. Then $\Delta\lambda/\lambda = 1.23 \times 10^{-6}$, so that each solar spectrum line should be shifted toward the red by a little over a millionth of its own wavelength.

Measurements of this precision are hardly possible at present. But there are other stars (in particular, the **white dwarfs**) so massive and so dense that the shift has actually been observed and found to be of the correct order of magnitude. (L.D.W.)

EINSTEIN THEORY. Relativity.

EJA. Reptilia, Sauria. The desert saw viper of Egypt, a vicious poisonous **snake.** (A.W.L.)

EJACULATORY DUCT. The portion of the male genital duct between the duct of the **seminal vesicle** and the **urethra.** (A.W.L.)

EJECTAMENTA. Volcanism.

EJECTOR. Any mechanism or device which can in some fashion remove an object or a material from a certain position, is rightfully called an ejector. Thus many machines are equipped with ejector elements the function of which is the removal of a part from one position to another. The pump which moves a fluid from some place where it is not desired is an ejector. A device employed to remove non-condensable gases from a steam condenser is called an air ejector. The steam-jet ejector is a widely used type, especially on large condensers. It consists of a steam jet receiving steam at a pressure from 100–250 lbs. per sq. in. The steam issues from the jet with high velocity, picking up such particles of air or other gas as may be entangled in the steam jet. The jet is then decreased in velocity, and a pressure built up. In this way, such gas as is entangled with the steam jet is compressed. (F.T.M.)

ELAEOLITE. Syenite.

ELAIOPLAST. A minute body in the cytoplasm of some **cells**, supposed by some cytologists to be a form of plastid about which fat is deposited. (A.W.L.)

ELAND. Mammalia, Artiodactyla. The largest African **antelopes.** The body is like that of a cow but the head is smaller and the horns are moderately long, straight, and spirally twisted. There are several species of the genus *Taurotragus.* (A.W.L.)

ELASTIC AXIS. Flexure.

ELASTIC CURVE. The curve of the **neutral** surface of a structural member subjected to **loads** which cause bending is called the elastic curve. The ordinates between this curve and the original position of the neutral surface represent the **deflections** due to bending. (C.W.C.)

ELASTIC LIMIT. The maximum unit **stress** which can be obtained in a structural material without causing a permanent **deformation** is called the elastic limit. (See **Ultimate Strength.**) (C.W.C.)

ELASTICITY. The property whereby a body, when deformed, automatically recovers its normal configuration as the deforming forces are removed. Each of its several types is probably due to the action of intermolecular forces which are in equilibrium only for certain configurations.

Deformation or, more briefly, strain is of various kinds; in each case its measure is a certain abstract ratio. For example, the elongation of a rod under tension is expressed as the ratio of the increase in length to the unstretched length. Linear compression is the reverse of elongation. They are both accompanied by a fractional change in diameter, the ratio of which to the elongation is called the Poisson ratio. Shear is a strain involving change of shape, such that an imaginary cube traced in the unstrained material becomes a rhombic prism. The measure of shear is the tangent of the angle through which the oblique edges have been made to depart from their original perpendicular direction. Volume strain is the ratio of a decrease in volume to the normal volume. **Flexure** or bending, and torsion or twisting, are combinations of these more elementary strains. A straight rod bent into a plane curve undergoes elongation on the convex side and linear compression on the concave side, while there is an intermediate neutral layer which suffers neither.

For every strain there arises, in an elastic substance, a corresponding stress, which represents the tendency of the substance to recover its normal condition. Stress is expressed in units of force per unit area. Tensile stress, for example, is the ratio of the force of tension to the normal cross-section of the rod subjected to it. Shearing stress is the force tending to push one layer of the material past the adjacent layer, per unit area of the layers. Pressure, expressed in like units, is the stress corresponding to volume compresion, etc.

For each type of strain and stress there is a modulus, which is the ratio of the stress to the corresponding strain. In the case of elongation or linear compression, it is commonly called Young's modulus; we also have the bulk modulus and the shear modulus or rigidity. (See **Tension Test.**)

In engineering design Young's modulus is used for tension and compression and the rigidity modulus for shear, as in torsion springs. Nominal values in lbs. per sq. in. are given for the principal classifications of structural metals (and their alloys).

MATERIAL	YOUNG'S MODULUS	RIGIDITY OR SHEAR MODULUS
Magnesium....	6.5×10^6	2.4×10^6
Aluminum......	10.2×10^6	3.6×10^6
Copper.........	14.5×10^6	6.1×10^6
Steel......	30×10^6	11.6×10^6

(L.D.W., R.H.H.)

ELATERITE. A variety of **bitumen** which is elastic when fresh but becomes hard and brittle when exposed to the air. (R.M.F.)

ELECTRET. Dialectric Absorption.

ELECTRIC AND MAGNETIC DOUBLE REFRACTION. In 1875 Kerr discovered that glass and many other isotropic, transparent solids and liquids exhibit **double refraction** like crystals, when placed in a strong electric field; and in 1905 Cotton and Mouton, after some preliminary results by Kerr and others, demonstrated the corresponding phenomenon with a magnetic field. These are now known respectively as the Kerr electro-optical effect and the Cotton-Mouton effect. In both cases the magnitude of the effect, as measured by the phase difference produced per unit thickness of medium, is, for a given substance, wavelength, and temperature, proportional to the square of the field intensity. The optic axis of the doubly refracting substance corresponds to the direction of the imposed field.

Of the two phenomena the Kerr effect is much more pronounced and is as yet the only one of practical importance. The Kerr cell, in which nitrobenzene, a liquid, is commonly employed because of its large and quick response to the electric field, has in recent years been extensively used as an electro-optical control or shutter for light beams, for example, in the recording of sound pictures. (L.D.W.)

ELECTRIC AND MAGNETIC UNITS. The measures of electrical quantities are based upon two quite distinct principles, giving rise to two distinct systems of electric units, which differ not only in size but in their physical makeup or dimensions; just as oil is measured and sold either by the gallon (volume) or by the pound (mass).

1. In the electrostatic system, the fundamental unit is that of quantity of **electricity**, defined as the charge which, concentrated upon a small sphere, repels a similar equal charge at unit distance (in a vacuum) with unit force. The c.g.s. electrostatic unit charge is the "statcoulomb," in which the unit distance is 1 cm. and the unit force is 1 **dyne**. It is equal to about 3.3×10^{-10} coulomb. Based on this is the seldom-used e.s.u. current or "statampere," which is 1 statcoulomb per sec.

2. The electromagnetic system, on the other hand, is founded upon the unit **electric current**, viz., the **abampere**, from which is derived the absolute **ampere**. The abcoulomb is 1 abampere per sec., and the absolute **coulomb** is $\frac{1}{10}$ of it. Aside from these are the international coulomb and ampere, defined electrochemically.

For some purposes it is convenient to use an e.s.u. of **electric potential** or of **electromotive force**, viz., the "statvolt," which is that potential difference through which the transference of 1 statcoulomb of electricity requires the expenditure of 1 erg of energy. But the practical e.m.f unit is the **volt**, similarly defined but in terms of the coulomb and the joule. The abvolt depends on the abcoulomb and the erg in the same way. There is also an international volt.

The practical unit of electrical **resistance** is the **ohm** (either absolute or international), equal to 10^9 abohms. The resistivity of a substance is commonly expressed in terms of the ohm-centimeter; i.e., as the resistance between opposite faces of a 1-cm. cube of the substance.

The practical unit of **capacitance** is the farad, which is 1 coulomb/volt, and is thus electromagnetic. The "abfarad" is the fundamental c.g.s. unit, 1 abcoulomb/abvolt or 10^9 farads. The microfarad (0.000001 farad) is commonly used in actual measurements.

The practical and fundamental c.g.s. units of **inductance** (or mutual inductance) are respectively the henry (defined under **Inductance**) and the abhenry, equal to 10^{-9} henry. The millihenry (0.001 henry) is usually more convenient.

The purely magnetic units begin with the concept of the unit magnetic pole (see **Magnetism**). The **oersted** and the **gauss** are respectively the units of magnetic intensity and magnetic induction. Often more convenient than the maxwell or "line" as a unit of **magnetic flux** is the "volt-second" or "weber," which is 10^8 maxwells. Magnetomotive force and magnetic potential may be expressed either in gilberts or in ampere-turns (see **Magnetic Circuit**). (L.D.W.)

ELECTRIC CELL. The electric cell is composed of two dissimilar metals or materials which are immersed in a solution capable of acting upon them chemically. A primary cell is one composed of two dissimilar electrodes which are immersed in a solution of an acid which acts more readily on one of the electrodes than on the other. The result of this chemical reaction is the production of an electromotive force. If the electrodes are connected by an external circuit, the electromotive force will maintain a flow of current through the circuit composed of the external connections, the electrodes, and the electrolyte. As current flows the chemical energy resulting from the action of the acid on the electrodes is converted into electrical energy.

A secondary cell is one in which electric current must first be passed between the electrodes of the cell under the influence of an externally generated electromotive force. The chemical action resulting makes the cell capable of giving off electric current by means of a secondary reversed chemical action. A group of secondary cells is a storage **battery**.

The physicist Volta discovered in 1800 that when two dissimilar metals were immersed in a solution such as sulfuric acid, they produced an electromotive force. By experimenting with different metals, he was able to arrange them in an electrochemical series which will show the relative electromotive force, and which of two elements used in a cell will be the positive, and which the negative electrode. A typical electrochemical series is as follows (for further details, see **Reactions Involving Oxidation-Reduction**):

Zinc
Iron
Tin
Lead
Copper
Silver
Platinum
Carbon (non-metal)

If any two of these metals are immersed in sulfuric acid the one nearest the top of the electrochemical series will be the positive electrode, and current will flow from it in the solution and to it in the external circuit.

A Voltaic cell is shown in Fig. 1. A simple cell of this type would soon become polarized. As current flows around the circuit, the following reaction takes place:

$$Zn + H_2SO_4 = ZnSO_4 + H_2.$$

The hydrogen thus liberated by the chemical reaction gathers on the negative electrode and, as a result, the electromotive force diminishes and finally disappears. This action is known as **polarization**, and must be overcome in any practical cell.

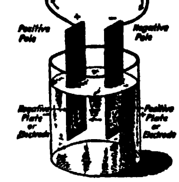


Fig. 1. Elementary cell.

There are many types of primary cells, amongst which might be mentioned the Daniell cell with zinc in sulfuric acid, and copper in copper sulfate: the LeClanche cell, using zinc and carbon in an aqueous solution of ammonium chloride; the Weston cell, with mercury and cadmium in a solution of cadmium sulfate. (See **Standard Cell.**) Depolarization in the Daniell cell is accomplished by absorption of the hydrogen by the copper sulfate, which is separated from the acid-filled portion of the cell by a thin porous partition, through which the hydrogen may pass. In the LeClanche cell, manganese dioxide,

a substance which gives off oxygen to combine with the hydrogen, is used as a depolarizer. The Weston cell is a voltage standardizing apparatus, and is not designed to produce a flow of current, but rather to yield a standard voltage for comparison. Its voltage is 1.0183 volts at 20° C.

The most widely used primary cell is the dry cell, whose popularity is the result of its portability and simplicity. Having no liquid electrolyte, the dry cell offers no danger from spilled acids; moreover, it is inexpensive and reliable, and long-lived when used for supplying intermittent currents, as for ringing doorbells, or with telephones, etc. The common dry cell (Fig. 2) has an electromotive force of about 1½ volts. The electrodes are zinc and carbon, with the former being in the shape of a cup some 2½″ in diameter by 6″ high for the standard type, although smaller sizes are used in flashlights. The carbon electrode is centralized in the zinc cup, and the space between carbon and zinc filled with the necessary electrolyte and depolarizer. The electrolyte is a damp sal ammoniac compound, and the depolarizer is manganese dioxide. The open end of the zinc cup is then sealed off with pitch or cement and binding posts are connected to the zinc and carbon. (F.T.M.)

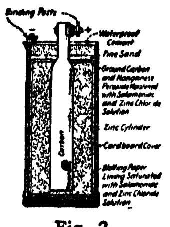

Fig. 2. Dry cell.

ELECTRIC CIRCUITS. The simplest type of electric circuit may be considered as beginning at any point and continuing without branching until that point is reached again. Along this closed path electricity moves because in some portion or portions of the path an **electromotive force** E is applied to it, doing work on the electricity and causing it to progress against the **resistance** as an **electric current**. It is convenient to divide the total resistance R of the circuit into two parts, the internal resistance R_i, viz., the resistance of that part in which the electromotive force is applied, and the external resistance, R_e, of that part in which no electromotive force is active. The current is the same through the whole of such a simple circuit, and its value, if constant, is given by **Ohm's law:**

$$I = \frac{E}{R} = \frac{E}{R_i + R_e}. \tag{1}$$

Let two points A and B be selected on the circuit and let the electric **potentials** at those points be respectively V_A and V_B. If the resistance of the part of the circuit between A and B is R_{AB} and if the part of the

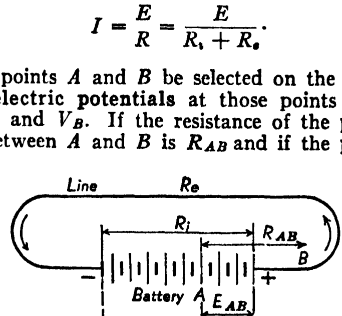

Diagram of simple circuit showing internal and external resistance. The two points A and B are selected at random; part of battery may or may not be included between them.

total electromotive force E applied to the circuit between these points is E_{AB}, then for the section AB, Ohm's law takes the special form

$$I = \frac{V_A - V_B + E_{AB}}{R_{AB}}, \tag{2}$$

in which E_{AB} is + or − according as it acts with or against the current. (The latter is illustrated by the part of a circuit containing a storage battery being charged or a motor exerting its back electromotive force.) We may equate (1) and (2), since the current is the same in all parts of the circuit; the potential difference between any two points A and B may then be calculated, thus:

$$V_A - V_B = \frac{R_{AB}}{R} E - E_{AB}. \tag{3}$$

If there is no active electromotive force in the part AB, then (2) gives $I = (V_A - V_B)/R_{AB}$. For any two pairs of points, A, B and C, D, since I remains the same, we then have

$$\frac{V_A - V_B}{V_C - V_D} = \frac{R_{AB}}{R_{CD}}, \tag{4}$$

the so-called "law of potential drop."

If the circuit has appreciable **inductance,** Ohm's law in its simple form (1) applies only so long as the current is constant. (See **Alternating Currents** and **Alternating-Current Circuits.**) Also, a circuit may be broken by a **condenser,** or have a condenser in parallel with it, or it may have appreciable **distributed capacitance;** in any such case its behavior upon the application of an electromotive force departs from Ohm's law. Divided circuits and networks, especially if they involve inductances or capacitances and carry variable currents, present somewhat complicated problems. (See **Kirchhoff's Laws of Networks.**) (L.D.W.)

ELECTRIC CONDUCTION. The conduction of electricity material substances is of two general kinds. 1. A migration of ionized (and hence electrified) atoms or molecules, as in **ionized gases** and electrolytes. 2. A process in which the atoms are in the main stationary, as in metals. This article deals with the second type only.

The electric conductivity of solids has an almost unbelievable range. For silver and sulfur (the best and the poorest among elements), the ratio is something like 1000 billions of billions to 1. Their resistivity is, of course, in the inverse ratio. (See **Resistance.**) Metals, as a class, aside from being almost immeasurably better conductors, differ in several respects in their conduction from non-metals. For example, the conductivity of pure metals consistently decreases with rising temperature, while the non-metallic solids, including carbon, generally have maximum conductivity at one or more temperatures. Selenium has most extraordinary properties (see **Photoconductivity**). Some metals exhibit **superconductivity** near the **absolute zero** of temperature. The alloying of metals, and even the admixture of small quantities of impurities, often profoundly affects the conductivity. Thus "constantan," an alloy of copper and nickel, shows almost no change of conductivity with temperature. The **Wiedemann-Franz law** expresses the remarkable relation which exists between the electric and the thermal conductivities of metals. The various **thermoelectric phenomena, thermionic phenomena, the Hall Effect,** etc., must also be taken into account by any theory of metallic conduction.

The idea proposed by Weber (long before electrons were known) and elaborated by Drude and Lorentz (with the aid of electron theory) has, until recently, completely dominated our thinking about metallic conduction. It supposes that good conductors contain electrons free to move about among the relatively fixed atoms; that when an electric field is applied to the conductor, the electrons drift along through it, colliding with the atoms and producing heat; and that poor conductors are such because few of their electrons are free. Tolman and Stewart (1916) tried suddenly stopping a metal rod in rapid longitudinal motion, and found that it became negatively charged at the forward end, as if the electrons had piled up there. A large number of experimental facts are in qualitative agreement with this theory. But two great difficulties are encountered: lack of even approximate quantitative agreement in many details, and the existence of certain stubborn anomalies; such, for example, as superconductivity and the conflict

between **Dulong and Petit's law of specific heats** and the principle of **equipartition of energy.** At present it appears that the solution of the difficulty may be a revision of our concept of the **electron** and its behavior, in terms of **wave mechanics.** (L.D.W.)

ELECTRIC CONDUCTIVITY. Resistance.

ELECTRIC CURRENTS. Electricity is a tangible thing, with some of the properties of ordinary matter, and among them the ability to move. Whenever it moves, we have an electric current. Since electricity may exist as separate electrons, protons, or positrons, or in collected charges of these entities, the electric current presents a variety of aspects. Usually we think of the progressive motion of electrons in a conductor, called **electric conduction,** or the two-way traffic of charged ions called "electrolytic conduction"; but the current may consist of a flight of electrons or other charged particles through a vacuum, or it may be a bodily movement of an electric charge, like that on one of the carriers of a **static machine.** Also there is that singular process assumed by Maxwell to take place in a **dielectric** or even in a vacuum, to account for the behavior of electromagnetic fields and radiation, and called the "displacement current." A current may be continuous, that is a progressive movement of electricity in one direction (the so-called **direct current**), or it may consist of temporary surges called **transients,** or be merely a vibration of the electricity with very short amplitude, as in **alternating currents** and **electric oscillations.** In conduction currents, contrary to the usual impression, the actual net progress of the electricity is very slow, seldom more than a few centimeters a minute. This is because of resistance and the continuous dissipation of energy in accordance with **Joule's law.** The speed of the electrons in a vacuum tube may, on the other hand, reach thousands of miles per sec. Electric impulses, or "compression waves," in a conductor also travel with great speed (in a telephone wire, many thousands of miles per sec.), and it is this property that gives electric communication the lightning-like rapidity commonly associated with electric currents. To drive electricity against its inertia or against the opposition of obstacles such as massed atoms or molecules requires **electromotive force.** If the electricity moves through any region where there is such opposition but with no battery or other source of electromotive force within that region to supply energy (as in a resisting wire), its motion is maintained at the expense of its own energy The **electric potential** changes as the electricity progresses, by an amount proportional to the potential energy which the electricity must thus give up. This leads to the familiar "law of potential drop." (See **Electric Circuits, Ohm's Law, Ampere, Electromagnetism,** etc.) (L.D.W.)

ELECTRIC DEGREE. Degree.

ELECTRIC DISPLACEMENT. Dielectrics.

ELECTRIC EEL. Pisces, Teleostei. A true **eel,** *Electrophorus electricus,* of the rivers of northern South America. It reaches a length of 6′ and is capable of giving a powerful electric shock. (A.W.L.)

ELECTRIC FIELD. Electrostatics; Fields of Force.

ELECTRIC FURNACE. An electrically heated furnace for the melting and alloying of metals. It is especially successful in the production of alloy steels, but is also used for non-ferrous alloys, particularly in the brass industry. The effect of the electricity upon the metal is purely to supply heat, there being no electrochemical action. The heating effect of the modern furnace is secured either by induction or by the use of the arc.

The high-frequency induction furnace may take several forms, the most usual being a refractory crucible surrounded by a water-cooled copper coil. Power in the form of high-frequency a.c. varying from 60 to 60,000 cycles per sec. is supplied to the coil from a suitable power supply such as a motor generator set which converts 60-cycle current to a higher frequency, a widely used value being 960 cycles per sec. Heat is produced in the metallic charge by means of eddy currents induced by the high-frequency field surrounding the coil. The

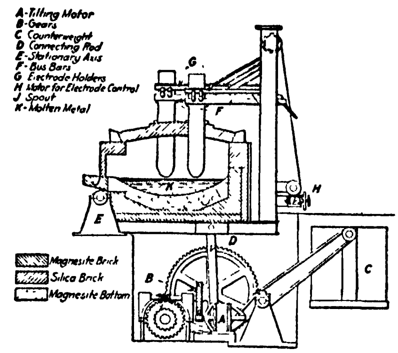

Fig. 1. Electric-arc melting furnace.

capacity of this type of furnace varies from a few pounds to as much as ten tons. Refractories used may be made of either quartz sand as in the "acid" crucible or magnesite as in the "basic."

The furnace is primarily a remelting furnace, very little refining or purifying of the metallic charge being accomplished. Close control of composition is accomplished by selection of raw materials, the speed of melting being such that control by chemical methods is impractical. Violent stirring of the molten charge as indicated by the arrows in the figure is produced by the interaction of

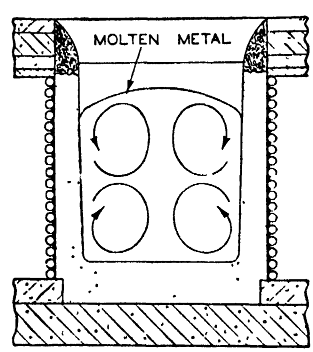

Fig. 2. Section of induction furnace showing stirring of the melt.

the eddy currents with the high-frequency field. Since lower frequencies are most efficient for stirring, many modern furnaces have two frequencies applied to the coil, a high frequency for rapid melting, and a low frequency for rapid stirring.

The type of arc furnace in most general use is the three-phase arc furnace invented by Heroult and bearing his name. The heat is produced in this furnace by three arcs striking directly to the bath from the electrodes which are usually made of carbon or graphite. Power is supplied to the arcs from large transformers and is regulated by automatic equipment designed to give minimum carbon contamination of the melt from the electrodes. The capacity of these furnaces varies from about ½ ton to in excess of 100 tons. These furnaces are primarily refining furnaces and may be either "acid"

where the refractories are predominately silica, or "basic" where the refractories are predominately magnesite. The basic furnace is the more widely used.

The operation of such a furnace is usually divided into two periods. First there is an "oxidizing" period in which the metallic charge is melted and held under a slag containing considerable iron oxide. This serves to eliminate carbon, silicon, phosphorus, and some sulfur. The "oxidizing" slag is then raked and poured off and a second or "reducing" slag usually very low in iron oxide and high in lime content is placed on the bath. This slag serves to eliminate sulfur and some other undesirable non-metallic material. The composition is adjusted to the desired limits, the temperature is raised to the proper value and the steel is poured into a ladle and from the ladle into ingots or into sand molds for the production of steel castings. Complete control of both temperature and composition have made this type of furnace the primary producer of high-quality alloy steels for use in the automotive, aircraft, and machine tool industries. (C. R. TAYLOR, AM. ROLLING MILLS.)

ELECTRIC HEATING. Electricity is employed for the generation of heat in industrial, commercial, and domestic use. When compared with direct heating from fuels, electric heating will show a much higher cost, since the equipment for converting heat energy into electrical energy fails to convert, at its best, some 70% of the heat units. Nevertheless, since electrical heating apparatus produces the heat at the very spot desired, and exactly in the desired amount, the difference in cost is not so pronounced, because of the economy of electric heating apparatus. For localized heating, such as cooking, soldering, and welding, electric heating is especially good; also it is used where cost is not an important item, viz., apartments, shipboard, hospitals, etc.

Heat may be obtained from electrical energy by means of resistance heating, induction heating, and the arc. Resistance heating is used in most domestic appliances, industrial ovens, and the like. Arcs are used for welding, lighting, and furnaces. (See **Electric Furnace, Arc Lamp.**) Induction heating has been employed in welders, furnaces, and therapeutic devices.

The amount of heat developed in resistance heating is proportional to the resistance of the heating element, and to the square of the current flowing. The electrical energy converted into heat when I amperes flow through a resistance of R ohms for t seconds is $I^2 \times R \times t$ watt-seconds. There are 1055 watt-seconds in a B.T.U. In resistance heating, it is essential that the resistor have little or no tendency to oxidation, a relatively high melting point, a high resistance so as to minimize the length of resistor, and minimum deterioration or embrittling upon repeated cycles of heating and cooling. Resistance wire used at present imperfectly meets these specifications. Nickel chromium steel wire is used in round and flat ribbon forms in various heating appliances. Insulation is usually by porcelain supports or mica. If, due to the convenience of application of heat, and the close control which can be exercised over temperature in electric heating, the product being subjected to heat can be made better, or with less labor, or with less wastage and spoilage, the higher cost of electric heating may often be more than overcome by savings in other lines. This has been true in cases such as ironing in laundries, cooking in candy manufacture, maintaining of glue pots, soldering irons, etc., at constant temperature, the even browning of loaves in bakers' ovens, the heating of presses and matrices, and a host of other heating applications.

In recent years advances made in domestic heating offer possibilities of electric heating for such purposes becoming economically feasible. Among these may be mentioned the system known as radiant heating. The first is based on the theory that most of the heat lost from the body is by radiation to colder surroundings. If, then, the walls of a room are heated there will be no absorption of radiation from the body and hence there will be no sensation of cold. While pipes carrying steam or hot water are used for this purpose, electric heating elements embedded in the walls offer enticing possibilities. (F.T.M., L.R.Q.)

ELECTRIC IMAGE. Electrostatics.

ELECTRIC INDUCTION. Electrostatics.

ELECTRIC INSULATION. Any **dielectric** is an electric insulator, but experience has demonstrated the value of certain solids, such as glass, porcelain, rubber, mica, silk, paraffin, etc., for practical use. Oil and air also are often used where the cooling of the conductor is necessary or where very high voltages are employed. Insulating material is commonly applied to a conducting surface for the prevention of current leakage, and to protect materials and persons in the vicinity of the surface. Electrical insulation is sometimes applied continuously to a conductor in the form of a complete covering like the rubber insulation on wires; or else the insulation may be applied at regular intervals like the porcelain insulating supports on an electrical bus-bar. With solid insulators, mechanical strength is often a consideration; as are also incombustibility, flexibility, non-hygroscopic character, high surface resistance, the ability to withstand high temperatures, the possibility of being machined or molded, and moderate cost. Low dielectric constant would also be desirable in cases where distributed **capacitance** is to be minimized.

The primary requirement of an insulator, however, concerns its insulating strength, that is, the maximum voltage per unit thickness which the material will sustain without electric breakdown or sparkover. (This is quite apart from its resistivity.) In reckoning this with alternating voltages, the maximum or peak voltage must be used, which is $\sqrt{2}$ or 1.41 times the effective voltage at which the service is rated. (Thus the insulation on a 11,000-volt line must be able to sustain 15,600 volts.) Solid insulators are sometimes subject to surface leakage, or conductivity due to films of moisture or other impurities; as well as to true conductivity of the insulator itself. The latter is not serious except in the case of the mountings of electrometers, ionization chambers, etc., where quantitative accuracy is desired, and for which one of the best insulators is found to be sulfur.

Vulcanized rubber compound and varnished cambric are the principal materials for insulating wires. For standard low-voltage wiring, the rubber is usually about 3/64" thick. Rubber-insulated wires are covered with a protective braid. Slow-burning wires are insulated with layers of braid impregnated with fire-resistant compound. Fine wire used in low-voltage coils is commonly insulated by simply applying a suitable varnish or enamel directly to the bare wire. (L.D.W., F.T.M.)

ELECTRIC MOMENT. Electrostatics.

ELECTRIC MOTOR. Motor, Electric.

ELECTRIC NETWORKS. Kirchhoff's Laws of Networks.

ELECTRIC OSCILLATIONS AND ELECTRIC WAVES. The most important early researches in this field were carried out by Heinrich Hertz, who, about 1888, discovered that when an electric discharge takes place in a **circuit** having suitable **inductance** and **capacitance**, the resulting oscillations of the **electricity** therein give rise to radiation, usually some meters in wavelength. The existence of the radiation was proved by its inducing oscillations in a similar circuit set up at a distance. He found that this Hertzian radiation (as

it is now called) can be reflected by metal surfaces and refracted by large blocks or prisms of dielectric material, just as **light** is reflected and refracted, and that it exhibits corresponding interference phenomena. The applications of Hertzian waves in radio are treated elsewhere. (See **Radio Communication.**)

The natural frequency of an oscillatory circuit or "Hertz oscillator" having resistance R (ohms), inductance L (henrys) and capacitance C (farads) is given by the equation

$$f = \frac{1}{4\pi}\sqrt{\frac{4}{LC} - \frac{R^2}{L^2}} \text{ (cycles per sec.).}$$

In using such formulae, the high-frequency values of R, L, and C must be employed, these being in general different from their low-frequency or steady-current values. The tuning condensers and inductance coils used in obtaining currents of desired frequencies are familiar to every radio amateur. High-frequency currents produced in this way range from 10 kilocycles per sec. for the longest radio waves (30 ki'ometers) to at least 75,000,000 kilocycles per sec. for the ultra short waves (4 mm.), detected some years since by Nichols and Tear and bordering on the infra-red. (See **Electromagnetic Radiation.**)

Electric waves may be propagated on long wires, somewhat as sound waves travel through a long tube. By terminating the wire in a small capacitance, the waves may be reflected and made to form interference nodes as do sound waves in an organ pipe. The wave length may be thus determined by what is known as the Lecher oscillator method, using two parallel wires.

It is often desirable to introduce into a communication line, such as a telephone circuit, a combination of inductances, or of inductances and capacitances, so designed as to form an effective barrier to currents of certain frequencies or frequency ranges, while others are allowed to pass through. Such arrangements, called wave **filters,** find many applications in modern electro-acoustic technology. (L.D.W.)

ELECTRIC POTENTIAL. If a charge of **electricity** is moved from one region of space to another, it encounters, in general, electric forces which either help or hinder the transfer and which therefore add to or subtract from the **potential energy** of the charge. Let us suppose that a positive unit charge has been brought into the region A from a region so remotely beyond the borders of the material universe that no electric forces exist there. In general, a certain amount of work, V_A, has been done against the electric forces encountered on the way in; consequently V_A may be regarded as the potential energy which the unit charge has acquired in the process. This work per unit charge, V_A, is called the absolute electric potential of the region A. It is a scalar quantity, and may be either positive or negative; for example if A is in the vicinity of a large negative charge, the unit positive charge has been attracted and has done work, or lost potential energy, during its journey, and V_A is therefore negative. If a second region B is at a potential V_B, less than V_A, the unit charge would lose potential energy in moving from A to B, in the amount $V_A - V_B$. Thus, in an electrolytic cell, a positive ion migrates from the high-potential to the low-potential electrode, and does work in heating the solution. Negative charges tend to migrate from lower- to higher-potential regions; this is illustrated by the electrons in a wire.

The absolute zero of potential is of course that at an infinite distance from the universe; but for practical purposes an arbitrary zero is used, commonly that of the earth's surface (which is by no means constant); or that of some other large **conductor,** such as the metallic base or case of the apparatus being used. The ordinary unit of electric potential is the **volt.** (See **Electromotive Force.**) (L.D.W.)

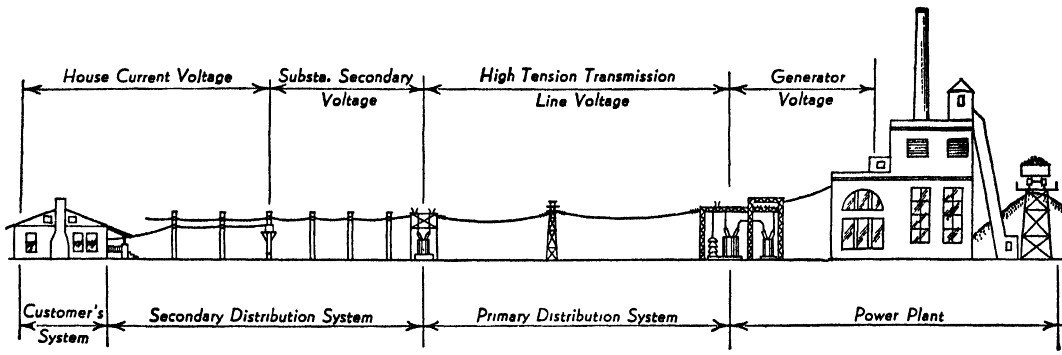
ELECTRIC POWER. Electric power is the product of **electric current** and **electromotive force;** that is, multiplication of current flowing by **voltage** forms the basis of the calculation of electric power. In a d-c circuit, the current measured in amperes, multiplied by the voltage between wires, is the power in **watts.** A thousand watts constitutes the kilowatt, a larger and more frequently employed unit of electric power.

The voltage and current may not be in phase with each other in an a-c circuit and, while the instantaneous power is the product of the instantaneous voltage and current, this out-of-phase relation causes the power to fluctuate between positive and negative values. Hence for the average power (which is usually what is desired) this factor needs to be taken into account in determining electric power in an a-c circuit, for it is only that component of the current which is in phase with the voltage that contributes to the average electrical power. The out-of-phase component produces the "wattless power." The power factor measures the fraction of the current that is in phase and available for true power. It is equal to the cosine of the phase difference between voltage and current. In a single-phase a-c circuit having current of I amperes, voltage of E volts, and power factor f, the true power is EIf watts. In a balanced three-phase circuit, it is $\sqrt{3}\ EIf$ watts. (See **Alternating Current, Direct Current.**) (F.T.M.)

ELECTRIC POWER TRANSMISSION. If power could be generated for the same cost at any point in the country, there would be no need for electric power transmission. But since the larger the electrical generating unit, the lower the unit cost of production, there has developed the method, so extensively used at present, of generating electric current in large **central stations.** From this has arisen the need for electric power transmission to carry the energy so produced to the users. The system of distribution extending from the generating station to the user is of varying complexity, depending on the number of customers and their location relative to the plant. From the standpoint of economy in power transmission, it is desirable to have the plant near the center of the load served, but other factors, such as suitability of sites, proximity of fuels, real estate costs, water supply, etc., are prominent influences bearing on the location of the generating station.

The physical system of conductors, whereby the generators are connected with the customers' lines, may be separated into two parts. These are shown in the figure. The primary distribution system generally consists of a transmission line carrying three-phase a.c. from the switchboard of the plant to a **substation** located near the load served. A secondary distribution system extends from the substation to the customer's site. The primary system is generally known as the transmission line; the secondary system as the distribution network. The first is characterized by relatively high voltage; the second by medium and low voltage.

Energy may be transmitted electrically in overhead wires or underground cables as an electronic flow under pressure. The flow is measured in amperes. The voltage is the electric pressure. Electrical energy is proportional to the product of these two quantities. This energy can not be transmitted without some losses, the principal one being a resistance loss, which depends upon the current flow and the size of the wire. In transmitting a given amount of energy, this loss may be reduced by increasing the voltage, since any voltage increase will allow a decrease of current. Or, from another viewpoint, for a given amount of energy, and a given permissible loss, higher voltages will permit the use of smaller wires. The foregoing should serve to show that, where practicable, electric power should be transmitted at high voltages. For various reasons this is not feasible in the distribution networks, but is so on transmission lines. In consequence, the operating voltages of the latter range up-



Elements of a power system.

wards from 6600 volts to nearly 300,000 volts. Commonly employed system voltages are 33,000, 66,000, 132,000, and 220,000. However, the higher voltages are strictly for overhead lines, cable transmission usually being limited to voltages lower than 40,000 volts.

These economic transmission voltages are higher than those under which power generating and utilizing apparatus can be operated, and a voltage transformation is essential if high transmission line voltages are to be used. By far the simplest and most effective means of accomplishing this is to employ a static **transformer.** The transformer may be used only with **alternating current,** and this goes far in explaining the prevalence of the a-c method of power transmission, because in many other respects high voltage d.c. is a superior means of transmission. As is shown in the diagram, the generator voltage is increased in the switchyard transformer to some economic transmission line value. The transmission line extending from station to load center may be of any length, as dictated by the geography of the locale; however, it does not commonly exceed 200 miles. Above some such distance the transmission line losses grow to where it becomes financially more attractive to build the generating station closer to the load and carry the energy to it by rail or water in the form of fuel. The longer lines are usually from hydro developments where the availability of water power offsets the line cost. At the receiving end of the transmission line, the voltage-decreasing transformer reduces the voltage to that which may be handled readily by the distribution network. This is often 2200 volts. At this voltage the energy flows through the network to the pole type transformers located close to the customer, or group of customers, it serves. At these transformers the voltage is reduced to 110 or 220 volts, in accordance with the customer's needs.

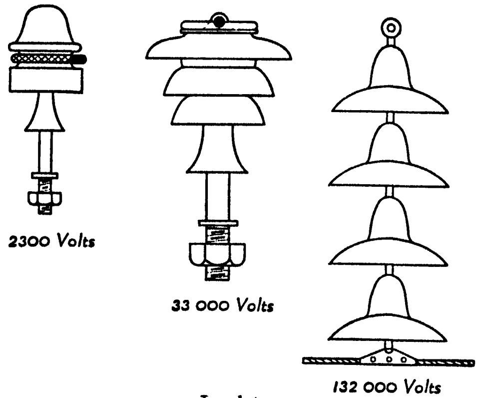
The energy loss occasioned by current flowing against the line resistance is not the only loss of energy in power transmission. The long stretches of parallel conductors have a capacitive effect, causing them to draw a current much as a **condenser,** even though the switches at the far end of the line are open. Furthermore, at high voltages, the air surrounding the conductors becomes partially ionized, and there exists a brush or **corona** discharge which represents a leakage of energy. The latter, as a matter of fact, is a limiting factor in the raising of electrical pressure on the transmission line and on the size conductor, and tends to offset the savings due to low current flowing when high voltages are used. Good transmission line design requires proper coordination of voltage, wire size, and line losses, so that the desired power may be transmitted at a minimum total annual cost.

When current flows on a long transmission line, the **inductance** of the line itself, plus its **capacitive** effect, combine with the **resistance** loss to give a voltage at the discharge end which varies with the load, even though the voltage is constant at the generator end. This feature is known as transmission line regulation, and is susceptible of prediction and analysis by theories developed by the electrical engineer. From the standpoint of the equipment served, it is desirable that this line regulation be offset so that lamps, heaters, etc., may operate on standard voltage. **Induction regulators** and tap-changing **transformers** are among the means employed to offset transmission line regulation. Furthermore, it is not difficult to demonstrate that the economy of power transmission varies as the square of the **power factor,** making it extremely desirable to operate the transmission line at unity power factor. On account of the induction characteristics of most electrical loads, and the capacitive effect of a transmission line itself, the current on a transmission line will tend to vary from lagging to leading, or vice versa with load, although customarily it tends to be lagging. For this reason, the synchronous motor is frequently employed for power factor correction, it being well known to have the electrical feature of drawing leading or lagging current, depending upon the amount of field excitation. Where this is not done, static capacitors are often added to improve the power factor.

The sheer physical extent of the ordinary transmission line makes it a likely victim of lightning, and no extensive transmission line could be successfully operated without adequate lightning protection. This may consist of **lightning arrestors** strategically placed, or an overhead grounded guard wire. Direct strokes are usually immediately dissipated by flash-over on the insulators, the lightning then finding its way down the pole to the ground. High-frequency induced waves (2000 to 5000 cycles) may not possess flash-over potential, and will travel along the line until relieved by an arrestor, or dissipated in resistance loss. Aside from lightning, a line should be protected against overload and short-circuits. This is commonly the function of transformer fuses, substation **circuit breakers,** and generator circuit breakers.

Turning from electrical to mechanical characteristics of electric power transmission, we find the material employed as conductor is universally either copper or aluminum frequently with a steel core for mechanical strength. The former is used in most cases, but the latter is in use for the very high voltage lines where, because of the larger diameter permitted by the lower density, it is effective in reducing corona loss. Except for very low-voltage distribution network lines, the wires are bare of insulation, and are carried by insulators of porcelain or glass of a design suitable for the voltage employed. Sometimes these insulators are mounted rigidly on the cross arm of the poles, but for the higher voltages they depend from the poles, and are known as suspension insulators. On high-voltage lines, each insulator is a chain of separate units, so that the voltage from line to pole may have a uniform gradient across the insulator. The distribution network and the low-

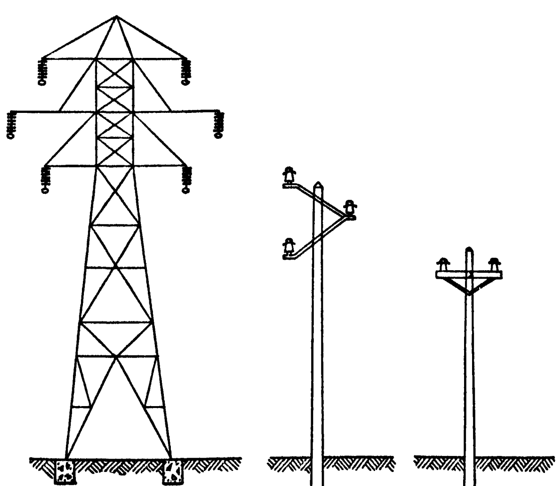
voltage secondary transmission lines are generally supported by wooden poles having cross arms. The pole most commonly used at present is of Southern pine, well



Insulators.

creosoted. These poles should be sufficiently high so that, at the middle of the span between them, the bottom of the wire sag has a minimum clearance over the ground. As specified in the safety code governing the industry, this clearance varies with the voltage and with the surroundings; for example, in rural districts, for line voltages of 15,000 volts, 18′ clearance should be maintained.

The spacing of poles must be chosen with due regard for temperature and sag conditions. Larger sags in the wire between poles give lower stresses in the wire, and permit the use of longer spans, but at the expense of the use of taller poles, needed to maintain the minimum clearance previously mentioned. Consequently, the observer may see extremes of design representing individual designers' viewpoints, varying from relatively low, closely spaced poles, with little sag, to long spans where tall poles are spanned by wire having a much greater sag. At the same time, the effect of contraction caused by lowering of temperature in winter, and the loads suffered during storms, particularly sleet storms, must be guarded against. While high voltage lines are frequently constructed on exceptionally high wooden poles(i.e., 50–80′), the steel pole or steel tower is the more frequently used. A common arrangement for high-tension transmission lines is the four-legged steel tower, as diagrammed in the accompanying sketch. This tower is conveniently arranged to support two three-phase circuits, and is frequently built as high as 100′, which permits extremely long spans because of the considerable amount of sag permissible. One hundred and ten thousand-volt transmission lines, so supported, are frequently run with no more than 6 or 8 towers per mile. (F.T.M.)



Typical supports.

ELECTRIC RATES. An electric utility company derives its revenues directly from the customers it serves on the basis of monthly billings. The customers' meter readings are put into the rate structure and the amount due from that customer determined. The apparent simplicity of the process is misleading, for the establishment of the rate structure that will fulfill the requirements of a successful working rate is a matter of no inconsiderable difficulty. From the public's standpoint the rates should meet the following conditions:

1. Rate schedudes should be simple. The problem of setting up a schedule that will fairly distribute the costs is aggravated by the necessity of its being comprehensible to the public as well as to the rate expert.
2. Rate schedules should be uniform over large territorial areas. There is much yet to be accomplished here Persons in one community frequently are paying on one basis, and those in the neighboring community on another which is so different as to be unintelligible to the first.
3. Direct service from producer to consumer. This requires the elimination of the energy jobber, subcontractor, or middleman.
4. Distribution of costs in such a way that persons creating a desirable and relatively inexpensive type of load may enjoy the full use and benefit of electrical appliances.

Scientific electric rate-making might be said to have originated with Dr. John Hopkinson, an Englishman who lived in the last half of the nineteenth century. The Hopkinson rate theory was based on two charges, one a fixed annual charge per kilowatt of maximum demand, the other a small unit charge against each kilowatt-hour of energy used. Other early leaders in rate-making theory were W. J. Green and Arthur Wright in 1896, and H. L. Doherty in 1900.

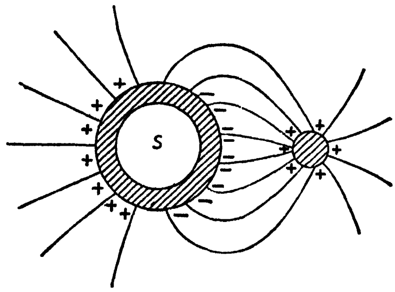
The following elements enter into the cost of electrical energy to the consumer:

Fixed element.
Energy element.
Variable load element.
Customer element.
Investors' profit.

The first of these is governed by the extent of plant investment and the current financial rates. It remains a fixed sum regardless of the amount of energy sold. The second is directly proportional to the plant output. The third, the variable load element, is governed by the characteristics of the load served, the load factor, the abruptness of the peaks, etc. The customer element will be proportional to the number of customers and nearly independent of both the plant investment and its kilowatt hour production. The profit is that which any sound normal business is expected to make. (F.T.M.)

ELECTRIC SCREENING. The experiments of Faraday revealed that any region completely enclosed by metal or other good **conductor**, however thin, is entirely free from **electrostatic** fields due to anything going on outside the enclosure. This is not because conductors are impervious to electric fields, but is due to the fact that the free **electrons** in the conducting shell surrounding the enclosure instantly adjust themselves so as to offset the effect of any electrostatic force that would otherwise penetrate the interior. Even a cage of fairly coarse screen wire is quite effective. Since **electromagnetic radiation** involves electric fields, we have here an explanation of why metals are opaque to it.

The screening effect of conductors is utilized in many kinds of electrical apparatus, as by enclosing electroscopes and the wires leading to them in metal cases or



Showing induction and external field. Space *S* is completely shielded.

conduits, the placing of metal covers over radio tubes, etc. Whole buildings are sometimes covered with sheet iron to prevent induction sparks due to lightning from setting fire to inflammable contents, such as gasoline or explosives. (See **Electrostatics; Coaxial Cables and Wave Guides.**) (L.D.W.)

ELECTRIC SYSTEM PROTECTION. The protection of **alternating current** cable networks and overhead transmission lines is a large and important field of electrical power engineering. The need for protection should be obvious. The nature of electrical phenomena is such that trouble may develop and lead to considerable damage to equipment before attendants are aware of it or before they can perform the protective operations manually. Not only will failure to protect the electrical equipment endanger the equipment itself; what is more important, it may also endanger life. Failure of generating station equipment involves more than the cost of repairs to such. It may mean complete shutdown or restricted output, bringing loss of revenue, complaints, and ill will of customers. Though often complicated, the protective system is not excessively expensive compared to the value of the equipment it protects.

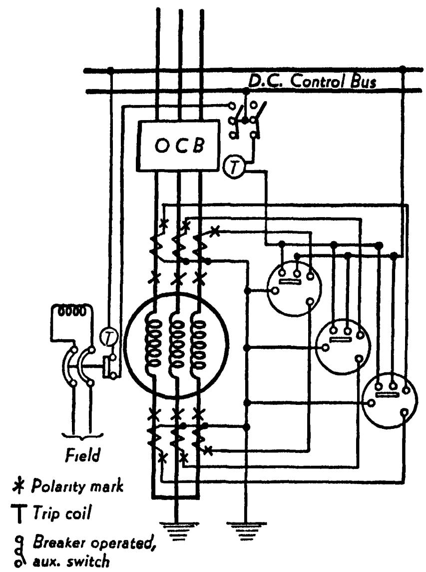
Protection is mainly against sustained overloads, high temperatures, and internal faults. In the case of **generators** or **transformers**, sustained overloads and high temperatures can usually be taken care of by the control room staff, guided by instruments indicating the magnitude of these abnormalities. They may be assisted by automatic relays giving audible or visual warning of these abnormalities when a predetermined value is exceeded. But upon internal fault developing, the equipment should be quickly and automatically disconnected. The internal faults may be short-circuited turns, open circuits, phase-to-phase short-circuits, or grounds.

The protective system should be satisfactory from the following points: 1. Selectivity. The protective system should be able to distinguish which portion of a sectionalized system is in trouble and to disconnect it only, leaving the remainder free to function normally. 2. Perception. It should distinguish between normal and abnormal conditions with a high degree of accuracy. 3. Sensitivity. It should not allow unduly large growth of the fault before the protective actions are completed.

The simplest protective apparatus is the fuse. The multitude of low-capacity, low-voltage power applications have made the fuse the most common protective device. All other protective systems are built around the circuit breaker.

The reactance of **alternator** windings or of added bus reactors is generally such that they can withstand a severe external fault such as a phase short-circuit without damage. Hence there is little value in protecting them against external faults. Alternator protection has resolved itself into protection against internal faults only, at least for large central station generators. Protection against internal faults is ordinarily restricted to the armature circuit because of the low voltage of the field windings and the rarity of trouble therein.

A differential scheme of alternator protection is one in which currents flowing in their proper paths between points to which protection extends (i.e., location of the



Differential generator protection.

current transformers), are so balanced against each other as to leave the relays unaffected. A diversion of current from the proper path, as through a ground fault, will divert current through the relay and cause it to function so as to clear the apparatus in trouble. Note that the amount of current flow has no effect on the relays as long as it is confined in the proper path.

Transformers represent a large investment. They are essential equipment, they can hardly be installed in duplicate, and therefore an adequate protection system is a necessity. The transformer should be guarded against overload, excessive temperature, and internal faults. As in the case of an alternator, protection against internal faults should be positive and rapid in action. Overheating and overloading generally manifest themselves by the same symptom—rise of temperature. The transformer may be protected against such by alarms which will warn the attendants of high oil temperature, incorrect flow of cooling water, etc. In some instances recording instruments are installed to take a continuous record of transformer temperature. The recorder can have auxiliary contacts which close an alarm or trip circuit when a predetermined temperature is exceeded.

Protection of motors is important. Continuity of service is considered so important in some cases that a burnout on overload is risked rather than to take unnecessary trip-outs. However, in other cases the protection applied includes under-voltage, no voltage, over-current, heating, grounds, open phase, and short-circuits. Periodically attended motors may have much simpler protection than others, this possibly extending to the use of indicating devices only, allowing the judgment of the operator to handle abnormal situations. Due to the common practice of full voltage starting, it is difficult to supply the motor satisfactorily with overload protection unless the starting current is made to flow in a line separate from that containing the protective devices.

Thermal fuses may be used for the smaller motors requiring only over-current protection. Thermal cutouts wherein a pair of spring contacts are secured together with a metal of calibrated fusibility are also used to protect the individual motor.

Station bus short-circuits and grounds are not common occurrences, yet they may be so damaging both to station and connected network that every effort is put forth to confine the evil effects to the locality in trouble and to disconnect it from the rest of the system as rapidly as possible. For this purpose buses are sectionalized by reactors, by automatically operated oil circuit breakers, or by both, or, being non-sectionalized, they can be protected by over-current relays or by differential protection.

Circuit breakers are installed at strategic points in a transmission system to open the circuit and remove a faulty section of the system before damage can occur to the rest of the equipment. The operating relays of these breakers have a wide variety of possibilities and the type used in connection with any breaker depends upon the system, the particular part of the system, and just how it is to be protected. Thus a simple over-current relay with a breaker might be used to isolate completely an entire system from the generator and remove the voltage from the fault. However, in most power systems, as has been pointed out, it is highly undesirable to interrupt service, and so various sectionalizing breakers with special types of tripping relays are used. (F.T.M., L.R.Q.)

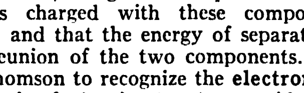
ELECTRICAL BRIDGE. The electrical bridge is a term referring to any one of a variety of electric networks, one branch of which, the "bridge" proper, connects two points of equal potential and hence carries no current when the circuit is properly adjusted or "balanced." This is well illustrated by the **Wheatstone bridge** and the **Carey-Foster bridge** for measuring **resistances.** Among many other important special types may be mentioned the following: the decade bridge, of the Wheatstone type, in which the ratio coils are decimal multiples of an ohm; the percentage bridge, in which a change of one division on the slide-wire scale corresponds to a change of 1% in the ratio of the compared resistances; the Callendar and Griffiths bridge, a special adaptation of the Carey-Foster type; the Thomson (Kelvin) double bridge, having eight arms and used for comparing low-resistance standards; the Wien bridge for a-c capacitances, the Nernst high-frequency capacitance bridge, and the farad bridge which reads capacitances directly in farads; the inductance bridge and the Heaviside mutual inductance bridge; the resonance and the Maxwell bridges for comparison of inductance with capacitance; and the frequency bridge, resembling the Wheatstone bridge but used for the measurement of alternating current frequencies. For details, the reader should consult works on advanced electrical measurement. (L.D.W.)

ELECTRICAL CONDENSER. An electrical condenser is an arrangement of conductors and **dielectrics** used to secure an appreciable capacitance, sometimes one of specified value. The essential feature of all condensers is a system of two or more conductors, separated by layers of dielectric. The potential difference between the conductors, when charged, is limited by the electric polarization in the dielectric. This makes it possible to accumulate large charges at comparatively small voltages. The oldest form of condenser is the **Leyden jar,** still often used where heavy electric discharges are desired. Many modern condensers consist of alternate metal and dielectric plates or sheets, sometimes of metal foil and paraffin paper strips rolled in a compact bundle. Condensers in which the dielectric is air, usually of adjustable capacitance, are much used in radio and other oscillatory circuits. An electrolytic condenser consists of an electrolytic cell in which a current has deposited a very thin layer of nonconducting material on one of the electrodes. This layer acts as the condenser dielectric. Such condensers have very high capacitance in proportion to their size and weight, and are much used in electric **filters** and other electronic apparatus. Standard condensers, of accurately known capacitance, are employed in electrical measurements. The capacitance of a condenser depends upon the total area a and the thickness d of the dielectric and upon its dielectric constant k. If the dimensions are in centimeters, the capacitance for a condenser of flat-plates is approximately given in electrostatic units by the formula $C = ka/4\pi d$ and in microfarads by $C = 8.84 \times 10^{-8} ka/d$. Thus, if there are 21 metal plates 10 cm. sq., separated by 20 sheets of mica 0.01 cm. thick and of dielectric constant 6, the capacitance is about 0.106 microfarads. The capacitance is often made adjustable by varying the distance d or by arranging the plates to move past one another so as to vary the area a of dielectric subject to the electric field between them. (L.D.W.)

ELECTRICAL INSTRUMENTS. Instrument, Electrical.

ELECTRICITY. The electrification of amber by rubbing with wool or fur was observed many centuries ago. Not until the work of Volta, late in the 18th century, was electricity recognized through any but electrostatic phenomena, and investigations on the properties and applications of **electric currents** were among the most brilliant features of 19th-century physics. Even in the 1890's physicists were still asking, "What is electricity?" It had then long been known that an appropriate application of energy will separate electricity into two components, designated as positive and negative; that bodies charged with these components attract each other; and that the energy of separation is yielded upon the reunion of the two components. It remained for J. J. Thomson to recognize the **electron,** and for the recent analysis of **atomic structure** to identify the proton and the positron. As a physical magnitude, methods have been devised for measuring quantities of electricity, not only in terms of the elementary electronic charge, but in larger units determined by electrostatic, electromagnetic, or electrochemical effects. (See **Electric and Magnetic Units.**) Among the most important aspects of the subject are the magnetic properties of moving electricity (**electromagnetism**) and the incorporation of both components of electricity in the structure of all atoms and molecules of matter. (See **Electrostatics.**) (L.D.W.)

ELECTROCAPILLARITY. The **surface tension** between two conducting liquids in contact, such as mercury and a dilute acid, is sensibly altered when an **electric current** passes across the interface. As a result, when the contact is in a capillary tube, the pressure difference on the opposite sides of the meniscus is affected by a current traversing the capillary column, to an extent dependent upon the direction of the current across the boundary. This has been utilized in different forms of capillary electrometer. In the Dewar type, two small



Capillary electrometer.

vessels of mercury are joined below the mercury level by a horizontal capillary tube, the mercury in which is interrupted by a short space filled with dilute acid. Upon applying a small potential difference to the two bodies of mercury, the equilibrium is disturbed and the drop of acid moves toward the low-potential end until the resultant capillary pressure is balanced by the hydrostatic pressure of the mercury. Since this effect is approximately proportional to the potential difference, the apparatus serves as a sensitive indicator for potentials of a few hundred millivolts. (See **Capillarity.**) (L.D.W.)

ELECTROCARDIOGRAM. A tracing on photographic film of the pathway traveled by the wave of electrical activity which sets off the contraction of the heart muscle with each beat of the heart. The electrocardiogram is a valuable diagnostic aid in heart disease.

Normally, the electrical current sweeps down from the heart's pacemaker in peristaltic waves over the auricles and by special conduction tracts and fibers into the ventricles. The electrocardiograph, which is essentially a string **galvanometer** with a photographic attachment, records this normal pathway as a series of waves or deflections of definite pattern. Deviations from the normal pattern occur in the form of changes in rate and rhythm, and in abnormalities of shape, direction, and amplitude of the individual waves. Such changes are often indicative of heart disease. **Arteriosclerosis** of the heart vessels and **coronary occlusion** result in heart muscle damage which may block the normal pathway and the electrical impulse must therefore pursue a different course in traversing the heart. Various disturbances in rhythm may follow interference with the normal conduction system. These are commonly associated with arteriosclerotic and **rheumatic heart disease.** (R.S.M.)

ELECTROCAUTERY. A cautery consisting of a platinum wire in a holder, which may be heated to any desired degree when electric current is supplied. (R.S.M.)

ELECTROCHEMISTRY. When substances are subjected to the **electric current** different results are observed, depending upon the nature of the substance. Solids such as metals and certain forms of non-metals, e.g., graphitic carbon, conduct the current without undergoing chemical change, whereas solutions of **salts, acids, bases** in water, and fused salts, acids, bases undergo chemical change at the **electrodes** upon passage of electric **direct current.**

The extent of chemical change is dependent in each case upon the amount of current which passes. One equivalent (see **Chemical Composition**) of **element, compound** or **radical,** is liberated per 96,500 coulombs of current (1 coulomb equals 1 ampere-second) (Faraday, 1833), at each electrode. The positive electrode *in the solution* is called the anode, and the reaction at the anode occurs by loss of negative charge of the anion. The negative electrode *in the solution* is called the cathode, and the reaction at the cathode occurs by loss of positive charge of the cation. The process itself is called electrolysis.

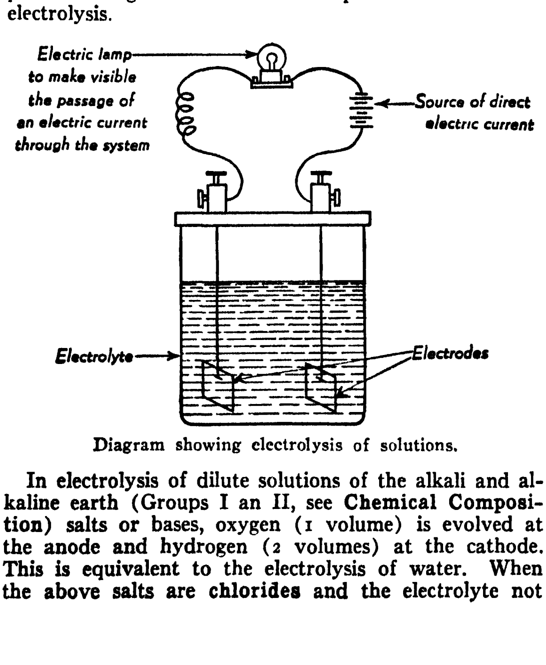


Diagram showing electrolysis of solutions.

In electrolysis of dilute solutions of the alkali and alkaline earth (Groups I an II, see **Chemical Composition**) salts or bases, oxygen (1 volume) is evolved at the anode and hydrogen (2 volumes) at the cathode. This is equivalent to the electrolysis of water. When the above salts are **chlorides** and the electrolyte not dilute, the reaction is more complicated at times. More or less **chlorine** is evolved with or without **oxygen,** according to the composition, concentration and mixing of the solution, the temperature, and the substance of which the anode is composed. Thus, with **sodium** chloride solution (1) chlorine is separated at the anode and **sodium** hydroxide at the cathode when a semi-porous diaphragm is used to separate mechanically but not electrically the anode and cathode compartments, (2) sodium **hypochlorite,** when the solution without a diaphragm is mixed by rapid stirring, (3) sodium **chlorate,** when the warmed solution without a diaphragm is mixed and the current is passed a long time, and, with sodium chloride fused, sodium metal at the cathode and chlorine at the anode. Graphite or amorphous carbon is used as a resistant anode, iron or nickel as cathode, and asbestos cloth as a diaphragm.

In electrolysis of many metallic salts, other than those of the alkali and alkaline earth metals, the metal is deposited at the cathode. **Copper** or **lead** is refined or deposited on another metal or on graphite by electrodeposition, **nickel, silver, gold, zinc, cadmium** or **chromium** is deposited in electroplating of objects, and **aluminum, magnesium, sodium** or **calcium** is produced by electrolysis of a fused electrolyte.

The electrical conductivity or conductance of an electrolyte depends upon the composition and concentration of the electrolyte, and on the temperature. Its value is expressed as reciprocal ohms, or mhos, and the equivalent conductivity is the conductivity of one equivalent weight of the substance at the given concentration and temperature when measured in a cell having two parallel platinized electrodes 1 cm. apart. In practice, the conductivity cell has two **platinum** electrodes each about 1 sq. cm. in area and is calibrated by the use of a standard solution.

ELECTRICAL CONDUCTIVITY OF POTASSIUM CHLORIDE SOLUTION AT 18° C.

Gram Mols per Liter of Solution	Conductivity (Mhos)	Difference in Conductivity between Successive Dilutions (Mhos)
1	98.2	
0.1	111.9	13.7
0.01	122.5	10.6
0.001	127.6	5.1
0.0001	129.5	1.9

The equivalent conductivity at zero concentration or infinite dilution is obtained by extrapolation of the curve plotted from the above values, and is in the case of **potassium** chloride at 18° C., 130.1 mhos. For **hydrochloric acid** the value is 379.5 and for **potassium** hydroxide 236.6.

The equivalent conductivity for each of the common anions and cations has been determined:

Hydrogen (H^+)	314	mhos
Sodium (Na^+)	43.5	
Potassium (K^+)	64.4	
Ammonium (NH_4^+)	64.5	
Hydroxyl (OH^-)	172	
Chloride (Cl^-)	65.5	
Nitrate (NO_3^-)	61.7	
Sulfate ($\frac{1}{2}SO_4^{--}$)	68	
Acetate ($C_2H_3O_2^-$)	34.6	

From these values the equivalent conductivity of acids, bases, salts may be ascertained, and in the case of electrolytes of low conductivity, for example, **acetic acid** and **ammonium** hydroxide, furnishes the accepted values.

The conductivity depends upon the velocity of each **ion** and upon the viscosity of the solution. Since the total current passing a given cross-section of the solution is carried partly by anions and partly by cations, the more rapidly moving ions (anions or cations, as the case

may be) carry more than half of the current. The fraction of the current carried by anions and by cations is proportional to the relative speed of each group. The result is that the faster ions crowd around their electrode to a greater degree than the slower ions around their electrode—the discharge at the electrode is strictly proportional to the current passing and is equivalent at each electrode. Under a potential gradient of one volt per cm. at 18° C. the speed of ions is as follows:

H^+	10.8	cm. per hour
Na^+	1.26	" " "
K^+	2.05	" " "
OH^-	5.6	" " "
Cl^-	2.12	" " "
NO_3^-	1.91	" " "

These values are practically in the same ratio as the equivalent conductivities of the ions.

The modern theory of electrolytic dissociation was announced by Arrhenius (1887) and extended by Milner (1912), Debye and Huckel (1923) and Onsager (1926). In the case of strong **electrolytes** like salts, **hydrochloric, hydrobromic, nitric acids, sodium, potassium,** quarternary **ammonium** (not ammonium), **calcium, barium** hydroxides, the dissociation into ions is complete. Changes in conductivity with changing concentration are due to the electrical effects of the ions upon each other. Each ion of positive or negative charge is surrounded in the solution by an ionic atmosphere of negative or positive charge, respectively. Weak electrolytes include ammonium hydroxide and many organic bases (see **Amines**), and practically all of the organic and some inorganic acids. These are slightly dissociated into ions.

Conductivity ratios at 18° C. of some weak acids are as follows:

Acid	Concentration	Ratio of Conductivity at Given Concentration to Conductivity at Zero Concentration at 18° C.
Carbonic	0 1 molar	0.002
Acetic. . .	1.0 normal	0 004
Hydrosulfuric . . .	0 1 molar	0.0007
Hydrofluoric .	1.0 normal	0 07
Boric	0 1 molar	0.001

Such acids are slightly ionized and the values given in the last column above represent practically the equilibrium fraction ionized at the corresponding concentration and temperature thus:

$$\text{Non-ionized Acid} \rightleftarrows H^+ + \text{Anion}^-$$

$$\text{Concentration:}\quad \frac{1-x}{v} \qquad \frac{x}{v} \qquad \frac{x}{v}.$$

Where 1 is the original amount, $1 - x$ the amount non-ionized under the conditions, and v the volume of solution.

Ostwald showed that, in each case of a weak electrolyte

$$\frac{\frac{x}{v} \times \frac{x}{v}}{\frac{1-x}{v}} = \frac{x^2}{1-x} \times \frac{1}{v} = \text{Constant.}$$

This constant is called the ionization constant of the acid or the base. (See **Acids, Bases, Salts.**) The less the ionization of the acid (or base), the nearer the constant approaches in value the product of the concentration of the two ions.

The intensity aspects of electrochemical reactions are discussed in the article on **Reactions Involving Oxidation-Reduction.** (R.K.S.)

ELECTRODE. In an electric circuit, part of which is composed of other than the usual conductor of copper, or other metal, the terminal connecting the conventional conductor and the conducting substance is an electrode. Examples of electrodes are to be found in the electric **battery,** where they dip in the electrolyte; the **electric furnace,** where the electrodes connect the external circuit with the heating arc, and in the electric chair, where the electrodes connect the external shocking circuit with the body. For electrode potentials, see **Reactions Involving Oxidation-Reduction.** (F.T.M.)

ELECTRODE POTENTIAL. Reactions Involving Oxidation-Reduction.

ELECTRODELESS DISCHARGE. There are two ways in which a current may be maintained in a rarefied gas without the introduction of **electrodes** into the gas. 1. A tube containing the gas may be placed between external metal plates having a rapidly alternating, high-potential difference. The tube then acts as the **dielectric** in a **condenser,** and the gas may become luminous with a discharge across the tube similar to that with internal electrodes. 2. The tube may be surrounded by a **helix** through which a high-frequency current is passing. In this case the luminosity takes the form of a ring, inside the tube, coaxial with the turns of the helix. This is due to the alternating electric intensity induced by the current in the helix. The discharge has the characteristics of the positive column in an ordinary discharge tube, except that it forms a closed ring. Striations sometimes appear, in radial planes. If the oscillations in the helix are intense, the ring discharge is confined to the space immediately inside the tube wall; if less so, it extends farther inward. The discharge is facilitated by **ultra-violet** radiation traversing the gas. Volatile impurities in the tube, such as sulfur or phosphorus, impair the discharge and may stop it. With some gases there is a distinct **phosphorescence,** called the "afterglow," persisting for some seconds after the helix oscillations cease. There is evidence that this effect is associated with impurities and is of chemical origin. (See **Ionized Gases.**) (L.D.W.)

ELECTROENCEPHALOGRAM. A record of the electrical potentials of the brain, which appear as waves of characteristic rate, amplitude, and rhythm. Abnormalities of these pictures aid in the diagnosis of such conditions as **epilepsy** and brain tumor. (D.M.H.)

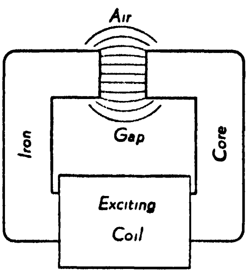
ELECTROLYSIS. The process of decomposition of an **electrolyte** by the passage through it of an **electric current** is electrolysis. In electrolysis, the body of the electrolyte must surround two **electrodes,** one called the anode, the other, cathode. Current flows from the anode to the cathode, and the dissociated parts of the electrolyte are liberated at the surface of the electrodes, that moving toward the anode being the anion, and, to the cathode, the cation. For example, a solution of copper sulfate, commonly called blue-stone, is an electrolyte. When a current is passed through it between two electrodes, the copper sulfate is broken down into metallic copper, which is deposited on the cathode in the form of a copper plate. The molecule of water is caused to liberate its oxygen, which appears at the anode, while the hydrogen unites with the sulfate iron to form a solution of sulfuric acid. Electrolysis of a damaging, uncontrolled nature sometimes occurs in buried water pipes or the reinforcement of concrete. It originates from stray lighting or traction currents. A damp soil is essential to action of this nature. (See **Electrochemistry; Reactions Involving Oxidation-Reduction.**) (F.T.M.)

ELECTROLYTE. This term is commonly applied to substances which either in the molten state or in **solu-**

tion conduct electricity by transfer of **ions**. The term is not applied to the metals in elementary form. Another usage is to apply the term electrolyte to the conducting solution itself. The more important electrolytes are solutions of salts, acids, or bases, usually in water. (See **Acids, Bases, and Salts; and Electrochemistry.**) (R.K.S., F.T.M.)

ELECTROLYTIC DISSOCIATION THEORY. Reactions Involving Recombination of Ions.

ELECTROMAGNET. A **magnet** whose field is produced by an **electric current**, and which is largely demagnetized upon cessation of the current, is an electromagnet. In order to obtain the strongest field possible, highly permeable soft iron or steel is employed for the core of electromagnets. In an electromagnet the current flows through a solenoid, which is a conductor wound in the form of a **helix**, and which produces a strong magnetic field coaxial with the helix. The core is placed inside the helix in order to give a magnetic path of the least reluctance. Electromagnets are found in a number of different forms, such as the plain solenoid with cylindrical core, or the horseshoe electromagnet, much used in electric bells, telegraph instruments, and telephones. Very powerful electromagnets are often used to move masses of iron, such as scrap iron, and have the advantage that the loading or unloading of the crane to which the magnet is attached is simply a matter of applying or disconnecting the electric current.



Sketch of electromagnet having two poles; one of a large variety of designs.

Typical electromagnet, carrying load. (*Electric Controller & Manufacturing Co.*)

For practical calculations we may write the Bosanquet law $\phi = \mathfrak{M}/\mathfrak{R}$ for the flux in a **magnetic circuit** in more useful approximate form:

$$\phi = \frac{nI}{5l/2\pi\mu a} = \frac{nI}{0.796l/\mu a}.$$

This refers to a simple, closed magnetic circuit of length l (cm.), uniform permeability μ, and uniform cross-section a (sq. cm.), excited by a magnetomotive force nI (ampere-turns). The denominator is the reluctance of the circuit. If either the permeability or the cross-section is not uniform, this reluctance must be separated into parts, each having its own value for l, μ, and a. For example, let us calculate the ampere-turns nI required to produce an induction of 2200 gausses in the air between the poles of an electromagnet having an iron core of permeability 1500 and cross-section 40 sq. cm., the distance around through the iron being 78 cm. and the single air gap 6 cm. wide. The required flux is 40 sq. cm. $\times$ 2200 gausses = 88,000 lines or maxwells. The reluctance of the iron part of the circuit is 0.796 $\times$ 78 cm. $\div$ 1500 $\times$ 40 sq. cm. = 0.001 reciprocal cm., and that of he air gap, 0.796 $\times$ 6 cm. $\div$ 1 $\times$ 40 sq. cm. = 0.119 reciprocal cm. (taking the permeability of air as 1); so that the total reluctance is 0.12 reciprocal cm. That is, 88,000 maxwells = $nI \div 0.12$ reciprocal cm., or nI = 10,560 ampere-turns. The result, though only roughly approximate, is sufficiently accurate for practical purposes. It is to be noted that since the air gap contributes by far the larger part of the reluctance, the flux is very sensitive to variations in its width. (F.T.M., L.D.W.)

ELECTROMAGNETIC CONSTANT. The speed of propagation of electromagnetic waves such as **light**, in a vacuum, commonly denoted by c, appears so frequently in physical formulae that it has become one of the most important of all physical constants. This is especially true since the advent of multitudes of formulae of **relativity** involving this factor. The precise determination of its value has justly, therefore, engaged the attention of the ablest experimenters.

Early attempts to measure the speed of light failed from lack of any adequate conception of the magnitude of the quantity to be measured. The first inkling of the truth was arrived at by Roemer in 1675, when he surmised that certain irregularities in the observed recurrence of the eclipses of Jupiter's satellites were due to the fact that time is required for the light to traverse the varying distance from Jupiter to the earth. The value thus calculated was not far from those obtained by the best experimental methods. The first direct determination was made by Fizeau (1849), who sent out a beam of light between the teeth of a rapidly revolving cogwheel, to be reflected by a distant mirror and returned in time to be stopped by the next tooth. Foucault (1854) improved upon this by using a revolving mirror, the beam finally reflected from which, after its return from a distant fixed mirror, was deviated because of the slight rotation of the revolving mirror during the journey of the light out and back. This method was later perfected and refined by Michelson and others. Michelson's final value (1930) was 299,772 kilometers per sec. The most probable value, as of 1941, is given by Birge as 299,776 kilometers per sec.

Aside from direct determinations of c as the speed of light, the constant has been deduced from measurements of standing electric waves on wires (Mercier, 1923), the result of which was 299,782 kilometers per sec.; and from the measured ratio of the abcoulomb to the c.g.s. electrostatic unit charge, the numerical value of which (according to Rosa and Dorsey, 1906) is 2.99781×10^{10}, giving c = 299,781 kilometers per sec. A careful comparison of the results of the direct and the indirect methods by Edmondson (1934) and others has led to the suspicion that the former are subject to some unexplained periodic influence, possibly associated with changes in the long base lines used in the measurements. The agreement and constancy of the indirect results are considerably better. (L.D.W.)

ELECTROMAGNETIC FIELD. It is commonly stated that a wire carrying an **electric current** is surrounded by a **magnetic field** whose lines of force are circles with the wire as their axis. This statement im-

plies that the magnetic field is directly traceable to the moving **electricity** in the wire. There is, however, another aspect of the matter. Each electric particle projects into space a radiating field of electric force, whose lines may be thought of as bristling out from the wire like the fur on the tail of an angry cat; and as the particles move alcng the wire the lines of force move with them. According to the theory of Maxwell, it is the motion of these lines of electric force that sets up the magnetic field transverse to them. More generally, a variable electric field, with moving lines of electric force, is always accompanied by a transverse magnetic field; and conversely, a variable magnetic field, with moving lines of magnetic force, is accompanied by a transverse electric field. The joint interplay of electric and magnetic forces here described is what is called an electromagnetic fie'd, and is considered as having its own objective existence in space apart from any electric charges or magnets with which it may be associated. An essential feature of the theory is that this process, whatever it is, represents a flow of energy at right angles to both electric and magnetic components. The flux density of this energy (corresponding to the intensity of radiation) is represented by what is known as the Poynting vector. **Electromagnetic radiation** is, on this theory, the propagation of these electric and magnetic stresses through space with the speed of light, somewhat as the much slower waves of elastic stress are propagated through steel. The conditions in an electromagnetic field are expressed mathematically by the well-known **Maxwell's equations.**

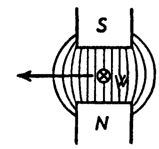
When an electric charge is set into motion, it builds about itself an electromagnetic field, and this implies a distribution of energy throughout space. The density of this energy at any point of the field is proporational to the product of the electric and magnetic **vector** components and the sine of the angle between them (vector product). The total field energy can be obtained by suitable integration, and is greater than that of the purely electric field of a stationary charge. Maxwell's theory treats this excess as kinetic energy, thus endowing the moving charge with an "electromagnetic mass" and an "electromagnetic momentum" inherent in its electrical character. That this may be the nature of all **mass** and **momentum** at once suggests itself when we consider the electrical constitution of matter, discovered since Maxwell's time. (L.D.W.)

ELECTROMAGNETIC INDUCTION. Probably the most noteworthy of the many scientific contributions of the renowned Michael Faraday was his discovery in 1831 of electromagnetic (or more logically, magneto-electric) induction. As exhibited in the usual experimental arrangements, this phenomenon is the setting up, in a circuit, of an **electromotive force** by reason of the variation of the magnetic flux linked with the circuit; the magnitude of that electromotive force being, as Faraday found, proportional to the rate at which the flux through the circuit, or the "linkage," varies. If the flux linkage with the circuit, in maxwell-turns, is expressed by $N\phi$ (the actual flux, ϕ, times the number of turns, N), the electromotive force generated by its variation, in volts, is:

$$E = \frac{N}{10^8}\frac{d\phi}{dt}.$$

(See **Volt.**) The electromotive force is positive (counterclockwise) when $\frac{d\phi}{dt}$ is positive, that is, when the flux is increasing, negative when it is decreasing; as viewed by one looking in the direction of the magnetic induction.

Another aspect of the matter is that if a conductor moves through a magnetic field, or if a magnetic field sweeps over a conductor, in such a way that the conductor cuts across the lines of force, the electricity in the conductor experiences forces at right angles to the field and to the (relative) motion. More general still is the Maxwell concept that when magnetic lines of force move sidewise, their movement results in an electric field at right angles to the magnetic lines and to their motion. (See **Electromagnetic Field.**)



Wire (W) moving to the left across an upward magnetic field has induced in it an e.m.f. away from the observer.

Faraday's discovery was almost accidental. Happening to thrust a bar magnet into a coil connected with a **galvanometer,** he noted a momentary deflection of the needle. If the north pole is thrust downward into the coil, so as to increase the flux linked with the coil, the current will be counterclockwise as viewed from above, and reverses on drawing the magnet out again.

The far-reaching consequences of this simple observation can hardly be overestimated. It was the forerunner of the invention of electric **generators** and **alternators,** of the original Bell telephone, of the **induction coil,** of the transformer, of the induction motor, of **magnetic damping** devices, and of many other electric appliances. It is the basis of **Lenz's law** and of the **Wilson experiment,** and the explanation of **eddy currents.** The **volt** and the **henry** are definable in terms of it. The phenomenon is called mutual induction when the variation of current in one circuit causes a variation of magnetic flux through, and hence an electromotive force in, another coupled circuit. It is a curious fact that in a vacuum the linkage through one circuit A due to unit steady current in a neighboring circuit B is equal to the linkage through B due to unit current in A; hence the mutual inductance of two circuits is the same, whichever is the primary circuit. If the circuits are closely coupled and have high self-inductance, and if an alternating electromotive force E be applied to A, the resulting a.c. induces an electromotive force in B approximately equal to $\frac{n_B}{n_A} E$; in which N_A and N_B represent the numbers of turns in the respective circuits. The principle is utilized in induction coils and in potential transformers. (L.D.W.)

ELECTROMAGNETIC MASS. Electromagnetic Field.

ELECTROMAGNETIC RADIATION. A century ago **light** was believed to be a transverse wave motion in an **ether** behaving like an elastic solid. Intensive study of the **electromagnetic field,** however, led James Clerk Maxwell (1873) to substitute electric and magnetic for elastic forces in the theory of light propagation. According to his view, light is the result of vibrating electric charges. These set up alternating **electric** and **magnetic fields** at right angles to each other and to the direction of propagation, which pass on the energy from one portion of the ether to the next as an electromagnetic wave. (Poynting's theorem states that the rate of this energy transfer is proportional to the product of the electric and magnetic intensities.) The theory was very successful in explaining many of the electrical and magnetic properties of light, such as the **Faraday effect** and the **Kerr effect.**

Maxwell suggested that it should be possible to produce waves of much longer wavelength than light by causing electricity to oscillate in a conductor. This was a forecast of the **Hertzian radiation,** upon which radio transmission depends, and which exhibits many of the characteristics of light, such as reflection, refraction, diffraction, interference, polarization, etc., but on a gross scale. Other researches showed that the **infra-red** and **ultra-violet** radiations have these same properties. It was therefore natural to classify them

together as the same phenomenon in different frequency ranges. **X-rays** for a time could not be identified with this group, but their diffraction by crystals finally demonstrated their wave character and they now take their place next to the ultra-violet. Meanwhile the **quantum theory** put a new aspect on the whole matter, and incidentally added the **gamma rays** to the radiation family. The table below gives the approximate wavelength ranges of these various types of radiation. It is quite probable that the very penetrating **cosmic rays** contain radiation of still higher frequency than the gamma rays. (See also **Thermal Radiation.**)

TABLE OF ELECTROMAGNETIC RADIATION

Type of Radiation	Approximate Range of Wavelength (in Cm.)
Gamma Rays	10^{-10} to 10^{-9}
X-rays	10^{-9} to 10^{-7}
Ultra-violet	10^{-7} to 4×10^{-5}
Visible Light	4×10^{-5} to 7.7×10^{-5}
Infra-red	7.7×10^{-5} to 0.4
Hertzian Radiation	0.4 to 3×10^{6}

(L.D.W.)

ELECTROMAGNETIC UNITS. **Electric and Magnetic Units.**

ELECTROMAGNETISM. The pioneer discovery of the magnetic effect of the **electric current** was made by Oersted at Copenhagen in 1820. In experimenting with battery currents, he happened to bring a compass needle near a wire in which there was an electric current, and noted that the needle was deflected. Such a wire is surrounded by a magnetic field so that, to one looking along the wire in the direction from the positive to the negative battery-terminal (the so-called "direction of the current"), the direction of the field, as indicated by the north pole of the compass needle, is clockwise (Ampère's rule).

If the wire carrying the current is placed in a magnetic field perpendicular to its direction, this field reacts with that due to the current in such a way as to give the wire a lateral thrust, perpendicular to both the wire and the field in which it is placed. For a wire of length l (cm.) carrying current I (amperes) and placed across a field of intensity H (oersteds), this lateral force is given by the equation $f = HlI/10$ (dynes); which follows from the definition of the **ampere.** An electric motor is driven by forces thus produced.

If the wire is bent into a circular loop of radius r (cm.), still carrying current I (amperes), there is produced at its center, perpendicular to the plane of the loop, a magnetic field of intensity $H = \pi I/5r$ (oersteds). This, and the statement in the preceding paragraph, may be shown to be interdependent. If more loops are added, forming a coil of n equal turns close together, the resulting field is n times as great. By winding the n turns along a cylinder, forming a "helix" of radius r and axial length a, one obtains something greatly resembling a bar magnet, the ends of the helix corresponding to the poles. The field intensity at the center of the axis of this helix (without any core) is

$$H_o = \frac{2\pi nI}{5\sqrt{4r^2 + a^2}} \quad \text{(oersteds).}$$

If we now insert an iron core, we have an **electromagnet,** and the helix supplies the magnetomotive force nI ampere-turns for a **magnetic circuit** composed partly of iron and partly of air.

More general calculations of electromagnetic effects are based upon **Ampère's law,** the **Biot-Savart law,** and **Maxwell's equations.** (L.D.W.)

ELECTROMETERS. **Electroscopes and Electrometers.**

ELECTROMOTIVE FORCE. Various means have been discovered whereby **electricity** may be propelled against any opposition such as the **resistance** of a conductor or the electromagnetic reaction of a motor. Thus we have batteries, generators, thermels, photovoltaic cells, etc., each of which has this electrical driving influence called electromotive force. The process of driving electricity against opposition requires the expenditure of energy. The electricity must have work done on it, and it, in turn, does work on something else. In an automobile headlight circuit, the electricity is able to do work on the lamp because, as it passes through the battery it receives a supply of potential energy. The **electric potential** where it emerges from the battery is therefore different from that at the entrance, and it is for this reason that there is a current through the lamp. The measure of the electromotive force of the battery is the work done on each unit of electricity as it passes through the battery. If this work is one joule per coulomb, the electromotive force is one **volt.** Frequently electromotive force is identified with difference of potential. This is permissible when the electricity gives up none of the energy while the work is being done, so that the resulting potential difference does actually correspond to the accession of energy. But the terminal potential difference of a generator and its electromotive force are in general not equal. (See **Electric Circuits.**) And it would be perfectly possible to arrange a circuit in which the electricity does work as fast as it receives energy and therefore moves along at constant potential; this is the case, for example, in a symmetrically placed, circular transformer secondary of one closed turn. (L.D.W.)

ELECTROMOTIVE SERIES. **Reactions Involving Oxidation-Reduction.**

ELECTRON. The first clear indication that electricity is composed of equal, elementary charges was afforded by **electrolysis.** (See **Charge-Mass Ratio.**) This gave, as the charge carried by a chlorine ion, 1.6×10^{-19} **coulombs** (negative); for the hydrogen ion, 1.6×10^{-19} coulombs (positive); for oxygen 3.2×10^{-19} coulombs (negative); for aluminum, 4.8×10^{-19} coulombs (positive); etc. We here have a common factor 1.6×10^{-19} coulombs or 4.8×10^{-10} electrostatic units. Sir J. J. Thomson (1897) succeeded in making a rough measurement of the charges carried by the **ions** of gases. Millikan used a much more precise method. It consists in measuring the speed with which a minute liquid drop is dragged along in an electric field when it picks up one or more stray air ions; the force acting on it being then deduced from the speed, and the charge, in turn, calculated from the force and the field intensity. He found this charge to be always a multiple of 4.77×10^{-10} electrostatic units—the same as that revealed by electrolysis. The most probable value at present (1945) is 4.8025×10^{-10} e.s.u.

Cathode rays and the beta rays from **radium,** when subjected by Thomson to measurement by a type of **mass spectograph** method, were found to be composed of particles having a negative charge of this value and a mass of about 9×10^{-28} gram. This mass is only about 1/1847 that of the lightest atom known,—hydrogen. For many years, no other particle was discovered having a mass comparable with it. The name "electron," suggested by Johnstone Stoney, is now given to any negative particle of this charge and mass, regardless of its origin. There is every evidence that not only are cathode and beta rays composed of electrons, but that swarms of these particles pervade all matter and play an important part in many physical processes such as **electric conduction, thermal conduction, magnetism, photoelectric phenomena, thermionic phenomena,** the emission of **light,** etc., as well as in chemical reactions.

In recent years it has been necessary to modify the concept of the electron as a mere electric particle and to recognize that it has wave characteristics, with a frequency and a wavelength. According to **wave mechanics**, an electron traveling with speed v is associated with a "de Broglie wave" train of wavelength $\lambda = h/mv$ (in which m is the electronic mass and h is Planck's constant), traveling with a speed greater than the speed v of the electron or even that of light, c, and equal to c^2/v. This concept gives the same frequencies for radiation emitted by atoms as the older Bohr theory. (See **Davisson-Germer Experiment.**) (L.D.W.)

ELECTRON GUN. **Cathode-Ray Tube; Electronics.**

ELECTRON LENS. **Cathode-Ray Tube.**

ELECTRON MICROSCOPE. The most outstanding achievement of electron optics (see **Electronics**) is the electron microscope. This instrument may be defined simply as a **microscope** in which streams of **electrons** function in essentially the same way as rays of light do in an ordinary optical microscope. When it is recalled that moving electrons exhibit properties characteristic of trains of waves (see **Wave Mechanics**), the analogy becomes still more striking; while the very short wavelength associated with electron waves serves to give the electron microscope extraordinary resolving power, thus making available **magnifying powers** far beyond the reach of any optical instrument.

The electron-optical system of this new microscope, as now usually constructed, consists of an electron gun (corresponding to a source of light) and a series of magnetic electron lenses which serve as condenser (to converge the rays on the specimen), objective, and projecting lens. Of course there is no eyepiece, since electron rays are not visible. So they must be made to form an image by projection, either on a fluorescent screen, which may be viewed through small windows in the case, or on a photographic plate, where the image is permanently recorded.

Magnetic lenses are of different types, and usually consist of a coil with iron pole pieces, so shaped as to give a "stray" field having lines of force with radial components symmetrically disposed about the axis. Unlike light rays, electron rays directed by magnetic lenses move in helical paths, so that the image is sometimes rotated many degrees with respect to the specimen. Focusing is accomplished, not by longitudinal movement as in optical instruments, but by control of the currents in the magnetizing coils, thus varying the focal lengths of the lenses. This accomplishes the result with great nicety.

Direct magnifications of as much as 30,000 diameters with resolving power to match, are entirely practicable. The enlarged photographic images thus obtained may then be still further magnified by ordinary optical means, so that over-all magnifying powers of 100,000 or more are now available. This brings within observation objects, such as very minute disease organisms, that have hitherto eluded detection. (L.D.W.)

ELECTRON MULTIPLIER. High-speed **electrons** impinging upon a metallic surface may cause other electrons to come from the surface. These secondary electrons as they are called may far outnumber the original or primary electrons. There are present in any conductor many so-called free electrons, that is, they are free to move at random in the material but not to leave it. If, however, they acquire more than a certain amount of energy, known as the work function, they may break through the surface restraints and leave the parent material. The high-speed primary electrons upon hitting the surface really penetrate it slightly and by colliding with the free electrons inside give them enough energy to overcome the surface attraction and leave. Since the primary electron may have several times the work function energy it may divide it among several electrons and thus cause several to be emitted. In certain electron tubes this principle is utilized to give current amplification. The electrons carrying the original current strike a surface which has been treated to enhance the effect and cause many secondary electrons to be emitted. These in turn are accelerated and directed against a surface, and so on, until after several stages many thousands of times more electrons have been obtained than were in the original current. Such tubes are called electron multipliers. (L.R.Q.)

ELECTRON OPTICS. **Electronics.**

ELECTRON VOLT. This is a convenient unit of energy for calculations in **electronics** and in connection with **ionization** or excitation of atoms or molecules. When an electric charge e is transferred from a region where the **electric potential** is V_1 to one where the potential is V_2, its potential energy changes by an amount equal to $e(V_1 - V_2)$. If the charge e is the electronic charge 1.602×10^{-19} **coulomb** (as it is when the transferred particle is an **electron**, a **proton**, a **positron**, etc.), and if the potential difference $V_1 - V_2$ is one **volt**, the corresponding change in energy is equal to 1.602×10^{-19} **joule** or 1.602×10^{-12} erg, and is called an electron volt. Thus if a doubly ionized positive oxygen molecule moves in an electric field through a potential-drop of 500 volts, it receives $2 \times 500 = 1000$ electron volts or 1.602×10^{-9} erg of energy; and since the mass of the oxygen molecule is about 5.31×10^{-23} grams, this energy would give the molecule, if unimpeded, a speed of about 7.77×10^6 cm. per sec. or 48.1 miles per sec. Careless writers often abbreviate electron volt to volt, a practice which should be discouraged. (L.D.W.)

ELECTRONIC ENGINEERING. This is the specialized branch of electrical engineering which deals with the design and application of electron **tubes.** While it is one of the newest branches of engineering it is rapidly becoming of great importance in the field. (L.R.Q.)

ELECTRONIC SWITCH. This is an **electron tube** device for alternately switching between two input signals. It consists of two amplifier channels, each fed by one of the inputs, arranged so they are alternately biased to cut-off (i.e., become inoperative) and feeding a common output. Thus while one channel is cut off, the other is amplifying its signal and feeding it into the output circuit. Then the first channel is cut off and the second becomes operative. One of the principal uses of the instrument is with the cathode ray **oscilloscope** where the switch is used to switch between two signals so rapidly that both signal waves appear on the oscilloscope screen. (L.R.Q.)

ELECTRONICS. The activity and the control of **electrons** have in recent years developed into an important field of physical science, called electronics. **Cathode rays, thermionic phenomena,** and **photoelectric phenomena** are separately treated elsewhere, as are also **electric conduction, thermoelectric phenomena,** and the **Hall effect** and allied effects in metals.

It was early learned that cathode rays are deflected by either a magnetic or an electric field. This has lately been utilized in various devices dependent upon the control of electronic motion, such as the **oscillograph** and the "electron gun" (a source of electrons with electrodes so charged and disposed as to project a sharply defined electron stream along a prescribed path). The fundamental facts are:

1. An **electric field** accelerates a free electron in the direction antiparallel to the electric intensity and with a force equal to 10^7Xe (dynes); in which X is the intensity in volts per cm. and e the electronic charge, in coulombs. The acceleration is therefore $10^7Xe/m$, where m is the electronic mass. Since for an electron the **charge-mass ratio** e/m is 1.76×10^8 coulombs per gram, the acceleration of an electron in a field of intensity X (volts per cm.) is $1.76 \times 10^{15}X$ (cm. per sec. per sec.).

2. If there is a component X of the field at right angles to the electronic motion, the electron moving with speed v (cm. per sec.), follows a curve whose radius of curvature is $r_X = 5.66 \times 10^{-16}v^2/X$ (cm.).

3. A magnetic field produces no acceleration in its own direction, but if there is a component of it, H (oersteds), at right angles to the electronic motion, the electron is deflected at right angles to both its motion and to the component H, following a curve of radius $r_H = 5.66 \times 10^{-8}v/H$ (cm.).

By designing electrodes and coils or magnetic pole-pieces so as to produce non-uniform electric or magnetic fields in various desired configurations, it has been found possible to act upon streams of electrons very much as lenses and optical instruments act upon rays of light, bending them, diverging them, or converging them to a focus. We thus have **electron microscopes** and electron image projectors, indeed, a whole new field of "electron optics." (L.D.W.)

ELECTROPHORUS. The simplest of all **static machines**; devised by Volta in 1816. It consists of a slab of some resinous substance, such as sealing wax or vulcanite, which is negatively charged by rubbing with fur. A metal plate provided with an insulating handle is placed upon the electrified slab. The contact is localized at a few points, so that instead of taking the negative charge off the slab, the metal plate becomes charged by induction, positively on the under side and negatively on the upper. The negative induced charge is now removed by grounding with the finger, and upon being lifted by means of the handle, the plate becomes positively charged all over, often strongly enough to yield bright sparks. Very little of the negative charge on the slab is removed in this process, and it may thus be used over and over to induce an indefinite number of positive charges. The energy is of course furnished by the operator in pulling the metal plate away from the slab. If a slab of glass is used, and rubbed with silk, it becomes positive and the induced charges on the plate are then negative. The instrument is useful in lecture-table demonstrations, in charging electrometers, etc. (L.D.W.)

ELECTROPLATING. The coating of an object with a thin layer of some metal through electrolytic deposition is known as electroplating. (See **Electrochemistry**; also **Reactions Involving Oxidation-Reduction.**) The process is widely used in numerous industries, either for the purpose of rendering a lustrous or non-corrosive finish on some article, or, as in electrotyping, being the principal part of the process. In electroplating, the general object is to employ the article to be plated as the **cathode** in an **electrolytic** bath composed of a solution of the salt of the metal being plated. The other terminal, the **anode,** may be made of the same metal, or it may be some chemically unaffected conductor. A low-voltage current is passed through the solution, which electrolyzes and plates the cathodic articles with the metal to the desired thickness. In this way table utensils are **silver** plated, various parts are made weather-proof by **cadmium** or **chromium** plating, and a high finish may be imparted through **nickel** plating. **Copper, zinc,** and **gold** are also plated. As the plating proceeds, the strength of the solution must be kept up by the addition of crystals of the plating salt, or a renewal of the anode if it is of the plating metal. A firm bond between the anode and the deposited metal is to be secured when the two metals are of a type which tends to alloy. If this is not the case, some intermediate metal, which will alloy between the base and the plate, is first deposited. For example, in silver plating, the iron would otherwise form a poor bond with the silver, so a thin layer of copper is first deposited on it.

Because of the excellent conducting properties of a metallic salt solution, only a low voltage is required. As this must be d.c., the process of electroplating calls for a supply of current from special low-voltage d-c generators. The voltage will be of the order of 6 volts or less between anode and cathode.

Some of the solutions used to plate various metals are as follows: for silver or gold plating, double **cyanide** of the metal and **potassium;** copper plating, copper sulfate; nickel plating, nickel ammonium sulfate. (See also **Galvanizing.**) The articles to be plated must be thoroughly and effectively cleaned of all grease and dirt by washing in caustic or acid solutions. While the above is a brief outline of the process of electroplating, in commercial operations there are many troublesome angles which would not be suspected from the foregoing. Irregularity of the plate, poor surface graining, "trees," insufficient bond, and other troubles creep in. The overcoming of these requires the use of various expedients, such as careful control of temperature, or the addition of certain colloids and other compounds which have been found effective in preventing formation of defects on the plated articles.

A particular and specialized branch of electroplating is the preparation of plates from printers' type, artists' engravings, etc. This art is known as electrotyping, and is an important phase of electroplating. To make a book plate, for example, melted wax is run over the printers' type as it is locked up in its frame, so that an impression of the type is made in wax. The surface of this wax impression is then made conducting by coating it with **graphite.** This is then put in an electroplating bath of copper sulfate, and a thin shell of copper built up over the wax mold. The shell can then be separated from the mold and backed up with type metal to give it body. Finally it is mounted on a wooden block for rigidity. (F.T.M.)

ELECTROPOLISHING. Production of a smooth **surface** on metals by **electrochemical** means.

In all **electroplating** processes metals (and hydrogen) are deposited on the cathode and dissolved from the anode, except when insoluble anodes are used in which case oxygen is liberated at the anode. Electropolishing is the reverse of electroplating. The work is made the anode and tends to be dissolved. The operating conditions are controlled so that atomic oxygen forms continuously and reacts with the metal surface. Part of this oxygen may be liberated as gas. According to one theory, the high points of the metal surface are most readily oxidized and this oxidized material is thereupon dissolved in the electrolyte or otherwise removed. In any case selective solution of the high points of the surface tends to give a very smooth finish comparable or superior to a mechanically buffed surface.

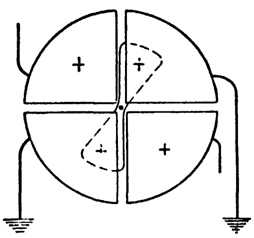
A wide variety of electrolytes is used. A typical one for **stainless steels** contains phosphoric acid and butyl alcohol.

All mechanical methods of polishing, including those used for **metallographic** samples, produce a thin surface layer of work-hardened metal. Electropolishing produces a strain-free surface which is especially suitable for microscopic examination.

An important commercial application of the process is the polishing of stainless steel parts of irregular contour which would be difficult or impossible to buff. Copper and its alloys, Monel metal, aluminum, and many other alloys can be electropolished. (R.H.H.)

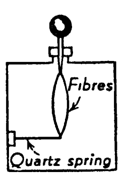
ELECTROSCOPES AND ELECTROMETERS. These are instruments for detecting small charges of **electricity**, or for measuring small voltages, or sometimes, indirectly, very small **electric currents.** One of the earliest sensitive electroscopes consists of two narrow strips of gold-leaf hanging together in a glass jar. Upon being charged, they stand apart on account of their mutual repulsion. One leaf may be replaced by a stiff strip of brass, so that only the remaining leaf can move. The Wilson electroscope has a single gold-leaf which, on being charged, is attracted by a grounded metal plate tipped at such an angle as to give maximum sensitivity. If the movement of the gold-leaf in an electroscope is observed through a microscope whose ocular is provided with a calibrated scale, the instrument becomes an electrometer, capable of measuring potential differences in microvolts. (Some forms of electrostatic **voltmeter** operate on the same principle.) If the **capacitance** of the charged system is known, the rate of movement of the electrometer index may be used to measure the current from the discharging body; ionization currents are often thus measured.

The quadrant electrometer has a thin, oblong, metal plate suspended horizontally in the interior of a flat,



Quadrants and strip of quadrant electrometer.

circular metal box cut into four quadrants. One pair of opposite quadrants and the suspended strip are connected to the source of potential, the other pair of quadrants is grounded. This causes the strip to turn toward the grounded pair against the torsion of the suspending wire. Several electrometers have been designed, depending upon the lateral deflection of a lightly stretched, silvered or platinized quartz fiber; they are called string electrometers. The Wulf electrometer employs two such fibers side by side; on being charged, they bulge apart. The displacement of the fibers is observed in a micrometer microscope. Some of the special electrometers used for work with **cosmic rays** are of this type. Recently the thermion vacuum tube (see **Triode**) has been adapted to the amplification of exceedingly feeble discharge currents, thus serving as an electrometer. (See **Capillary Electrometer.**) (L.D.W.)



Quartz fiber electroscope or electrometer.

ELECTROSTATIC DEFLECTION. Cathode-Ray Tube.

ELECTROSTATIC UNITS. Electric and Magnetic Units.

ELECTROSTATICS. While moving **electricity** has certain properties peculiar to its motion (see **Electric Currents, Electromagnetism**), in electrostatics we are concerned with phenomena exhibited by electricity whether in motion or at rest. The outstanding elements of the subject are electric charges, electric fields, electric induction in conductors, and electric polarization in **dielectrics.**

Owing to the tremendous mutual repulsion of all electricity for electricity of the same kind, it is impossible to gather together any considerable quantity of free electricity, positive or negative, in a limited space. To place a single coulomb of either sign on a metal sphere 10 cm. in diameter would require 4.5×10^{17} ergs of energy, equal to the output of a 100-hp. motor running continuously for a week; and its sudden release would rival the explosion of a carload of dynamite. But we can collect and experiment with very small charges. It is found that their attractions and repulsions obey **Coulomb's law** of inverse squares, and are also definitely dependent upon the dielectric constant of the surrounding medium. Faraday showed that any charge, imparted to a conductor, at once seeks the outside surface and so distributes itself there as to produce no influence anywhere inside. The **electric potential** of such a conductor is uniform both over its surface and throughout its interior.

The space outside in the neighborhood of the charge is, however, an electric field, as shown by the fact that a small charged body placed anywhere in it is urged by a definite force in some definite direction. Such a field may be mapped out by lines of force as in the case of a **magnetic field.** (See **Fields of Force.**) The electric intensity at any point of an electric field is measured by the force exerted upon a free unit charge placed at that point, and its direction is that of the force on a positive charge.

If a pair of equal, opposite charges at a fixed distance apart, called an "electric dipole," is placed in an electric field, it experiences in general a torque (like a bipolar magnet in a magnetic field). The maximum torque thus produced by a field of unit intensity is called the "electric moment" of the dipole; its magnitude is the product of either charge by the distance between them.

When a neutral conductor is placed in an electric field, it develops charges on opposite sides, the positive charge being on the side toward which a free positive charge is urged. The conductor has thus acquired an electric moment. This is thought to be due to a shifting of the **electrons** in the conductor until the region inside the conductor again attains the condition of zero intensity and uniform potential (see **Electric Screening**); and the process is called electric induction. The **electrophorus,** for example, utilizes this principle, as do other **static machines.** When a concentrated charge is brought near a large conducting surface, the charge thereby induced on the latter has in some respects the effect of a second concentrated charge, of opposite sign to the first, and lying behind the conducting surface; which gives rise to the idea of an "electric image," sometimes useful in electrostatic calculations.

If the object placed in the electric field is a dielectric or non-conductor, while there is no true induction, something like a stress, called an electric polarization, develops within the dielectric. This condition is the essential feature in the operation of a **condenser,** and its existence profoundly affects the **capacitance** of the conductors whose charges are responsible for the field. (L.D.W.)

ELECTRUM. Electrum is a native alloy of **gold** and **silver** in which the latter metal may be present in quantities up to 40%. Electrum from the Urals is said to carry 20% **copper.** The color of electrum is a pale yellow or yellowish-white and the name is derived from the Greek word mentioned in the "Odyssey," meaning a metallic substance consisting of gold alloyed with silver. This same word was also used for the substance **amber,** doubtless because of the pale yellow color of certain varieties. (E.S.C.S.)

ELEMENT, CHEMICAL. Chemical Composition.

ELEMENTARY CHARGE. Electron

ELEMENTARY QUANTUM OF ACTION. Planck's Law.

ELEPHANT. Mammalia, Proboscidea. The largest existing land animals. Characterized by massive structure and by the elongation of the nose and upper lip to form a long prehensile proboscis or trunk. The two upper incisors develop into long tusks in the male and the broad grinding molar teeth grow into position gradually as they are worn off during the life of the animal.

Two species of elephants are recognized, the Indian, *Elephas maximus,* and African, *Loxodonta africana.* The former averages 8–9′ in height and the latter about 10′, although occasional specimens of both species considerably exceed these figures. The African elephant has much larger ears than the Indian and its tusks average somewhat heavier.

The Indian elephant is tamed for use as a beast of burden and for handling heavy materials, such as timbers. It does not breed freely in captivity, hence wild herds are the source of supply. The animals are caught or trapped by various methods.

Elephant tusks are the chief source of ivory, single tusks running from 90 to almost 200 lbs. in weight. (A.W.L.)

ELEPHANTIASIS. Filariasis.

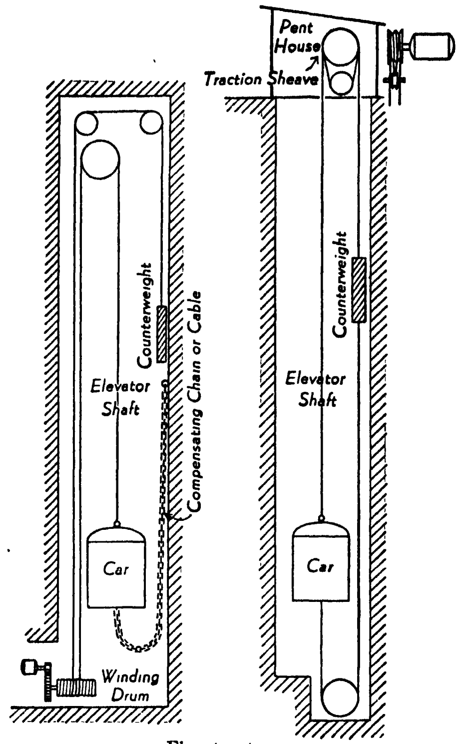
ELEPHAS. Fossil Mammals.

ELEVATOR. A movable auxiliary airfoil, the function of which is to impress a **pitching moment** on the aircraft. It usually is hinged to the stabilizer. (F.T.M.)

ELEVATORS. Elevators are hoists for lifting passengers and freight within the confines of a building, usually by means of a car operating vertically in an elevator well—an open vertical shaft extending from top to bottom of the building. The direct acting hydraulic elevator with a long **piston** working in an upright **cylinder** set deep in the ground, carrying on top of it the car, has been superseded by electrically driven elevators because it had limitations as to height of the building that it could serve, and operating speed.

The electric elevator may be of the winding drum type, or of the traction-sheave type. Both of these are illustrated in the accompanying figure. The winding drum elevator has a drum with spiral groove on its face, on which is wound a turn or two of wire rope. The ends of this rope are connected respectively to the counterweight and to the car. In actual practice two ropes are attached to each, this having the advantage of smaller rope size, permitting greater flexibility. The counterweight moves in a direction opposite to the car, and has a mass sufficient to balance the weight of the car plus 30–40% of its maximum live load. The winding drum is driven by an electric motor through a reduction gear consisting of helical gears, or worm and spur gears. The reduction on freight elevators is larger than passenger elevators, since they are required to carry heavier loads, and high speed is not as essential. Since the rope winds around the winding drum, whose surface is grooved, it moves back and forth on the surface of the drum as the elevator is operated, and the face of the drum then is proportional to the height of the building. This limits the height to which winding drum elevators can be applied, and the high-lift, high-speed passenger elevators necessary for tall office buildings are of the traction-sheave type, also illustrated.

The car of a traction elevator is moved by friction existing between traction sheave and rope. A secondary, or idler sheave, near the traction sheave, provides for the return of the rope around the traction sheave a second time, as this has been found necessary in order to develop the high degree of friction required. The traction sheave may be used without reduction gearing between motor and sheave. The gearless traction elevators are driven by large slow-speed motors having the traction sheave mounted on the same shaft with armature and brake pulley. These electric elevators may be used in the tallest buildings, since the face of the traction sheave is independent of building height. The



Elevator types.

motor and sheave must be mounted atop the elevator well. Elevator speeds, formerly limited to 100 to 200 ft. per min., have, with the gearless traction type, been advanced as high as 1000 ft. per min. (F.T.M.)

ELINVAR. Nickel Alloys.

ELK. Mammalia, Artiodactyla. In European usage, *Alces,* the animal called the moose in North America. In American usage, *Cervus,* a large **deer** of the western and northern parts of the continent, also called the wapiti. (A.W.L.)

ELLIPSE. An ellipse is one of the class of curves called **conic sections.** It may be obtained by cutting a right circular **cone** by a plane which cuts all the elements of the cone but which is not perpendicular to the axis of the cone.

An ellipse is the **locus** of a point which moves so that the sum of its distances from two fixed points remains constant. The fixed points are called the foci, the point midway between them is called the center. The line through the foci and the line through the center perpendicular to the preceding line are axes of symmetry, and the curve is symmetric about the center. (See Fig. 1.) The line through the foci cuts the curve in two points

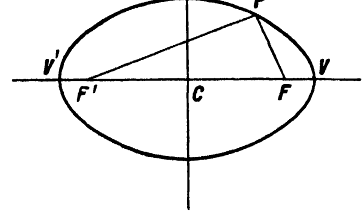


Fig. 1. Ellipse.

called the vertices; the segment (or length) joining the vertices is called the major axis; the distance between the points where the line through the center perpendicular to the line through the foci cuts the curve is called the minor axis. The major axis is equal to the constant sum of the focal radii in the definition of the curve.

The length of the semi-major axis is usually denoted by a, and the length of the semi-minor axis by b; the distance between the center and a focus is usually denoted by c.

The chord through either focus perpendicular to the major axis is called the latus rectum (or focal width) of the ellipse.

The eccentricity of the ellipse is the ratio $c/a = e$ of the distance between center and focus to the semi-major axis; it is a proper fraction ($e < 1$). It determines the shape of the curve; if e is near 0, it is nearly circular, and if e is near 1, it is elongated (narrow).

The standard equation of an ellipse in **rectangular coordinates** is

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1,$$

where a and b are the semi-major and semi-minor axes, respectively, and the center is at the origin and the major axis is along the X-axis.

The relation between the semi-axes a and b and the distance c between center and focus is $b^2 + c^2 = a^2$.

The two lines $x = \pm \frac{a}{e}$ are called the directrices of the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$. They have the property that the ratio of the distance of any point on the ellipse from a focus to the perpendicular distance of the point from the corresponding directrix is equal to the eccentricity.

The equation $\frac{(x-h)^2}{a^2} + \frac{(y-k)^2}{b^2} = 1$ represents an ellipse with center at (h, k) and axes of symmetry $x = h$ and $y = k$.

The ellipse may be constructed geometrically in several ways.

One method is the following, by continuous motion: Place two tacks in a drawing board at the foci F and F' and wind a string about them as indicated in Fig. 2.

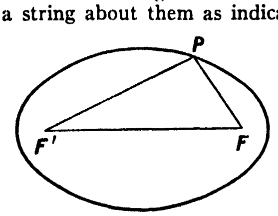

Fig. 2. Construction of ellipse.

If a pencil is placed in the loop FPF' at the point P and is moved so as to keep the string taut, then P describes an ellipse. If the major axis is to be $2a$, the length of the loop FPF' must be $2a + 2c$, where $2c$ is the distance between the foci.

A construction by ruler and compasses is as follows (Fig. 3): Draw circles on the major and minor axes AA'

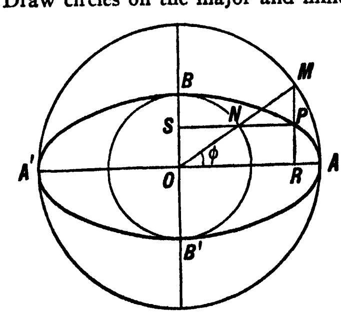

Fig. 3. Construction of ellipse.

and BB' as diameters. From the center O draw any radius intersecting these circles in M and N respectively. From M draw a line MR parallel to the minor axis, and from N a line NS parallel to the major axis. These lines will intersect in a point P on the ellipse.

The angle AOM is called the eccentric angle for the point P. The two circles are called the major and minor auxiliary circles.

The simplest **parametric equations** of an ellipse are:

$$x = a \cos \phi, \quad y = b \sin \phi,$$

where ϕ is the eccentric angle of the point $P(x, y)$, and a and b are the semi-axes of the ellipse.

The equation of the **tangent** to the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ at the point (x_1, y_1) is $\frac{x_1x}{a^2} + \frac{y_1y}{b^2} = 1$.

The equation of the tangent with slope m to the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ is $y = mx \pm \sqrt{a^2m^2 + b^2}$.

The area of an ellipse is πab, where a and b are the semi-axes.

Some of the applications of the ellipse are:

The orthogonal projection of a circle on a plane oblique to the plane of the circle is an ellipse.

Elliptical gears are used in machines, such as hay presses and power punches, where a slow, powerful motion is needed in a part, only, of each revolution.

The arches of stone and of concrete bridges are frequently constructed in the form of semi-ellipses.

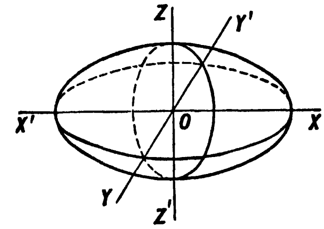
The **orbits** in which the **planets,** including the earth, revolve around the sun, are ellipses.

A crescent, such as the crescent **moon,** is bounded by a semi-circle and a semi-ellipse. (L.L.S.)

ELLIPSOID. The surface represented in **rectangular coordinates** by the equation $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$ is an ellipsoid; it is one of the **quadric surfaces.** It has a center at the origin, three principal axes (of symmetry) along the coordinate axes, all elliptic sections, and semi-axes a, b and c. It is a closed surface.

The volume of an ellipsoid with semi-axes a, b, c is $\frac{4}{3}\pi abc$.

If $a = b$, one set of sections consists of circles, and the surface is called an ellipsoid of revolution, which may be



Ellipsoid.

generated by revolving an **ellipse** about its major or minor axis.

The ellipsoid of revolution obtained by revolving an ellipsoid about its minor axis is called an oblate spheroid; the one obtained by revolving about the major axis is called a prolate spheroid. (L.L.S.)

ELLIPSOIDAL HEAD. Pressure Vessels.

ELLIPTIC COORDINATES. Elliptic coordinates are three numbers which determine the position of a point in space; they are used in certain special types of problems of geometry and mathematical physics.

The **surfaces** represented by the equation in **rectangular coordinates:**

$$\frac{x^2}{\lambda - a} + \frac{y^2}{\lambda - b} + \frac{z^2}{\lambda - c} - 1 = 0,$$

where λ is a variable parameter, with $a > b > c > 0$, form a family of **confocal quadrics.** Through each point (x, y, z) of space there pass three surfaces of the family. The equation above has three roots $\lambda_1, \lambda_2, \lambda_3$ for λ for a given set of values of x, y, z. These three roots $\lambda_1, \lambda_2, \lambda_3$ determine the point (x, y, z), and are called the elliptic coordinates of the point. (L.L.S.)

ELLIPTIC GEOMETRY. **Non-Euclidean Geometry.**

ELLIPTIC HYPERBOLOIDS. **Hyperboloids.**

ELLIPTIC INTEGRALS AND FUNCTIONS. Any **integral** of the type $\int R(x, y)dx$, where R is a **rational function** of x, y, and where y is a square root of a third or fourth degree **polynomial function** of x, is called an elliptic integral.

These integrals may be expressed in terms of elementary functions and one or more of the following type forms of elliptic integrals:

$$F(k, \phi) = \int_0^\phi \frac{d\phi}{\sqrt{1 - k^2 \sin^2 \phi}} \quad (0 < k < 1)$$

called the elliptic integral of the first kind in Legendre's form;

$$E(k, \phi) = \int_0^\phi \sqrt{1 - k^2 \sin^2 \phi}\, d\phi \quad (0 < k < 1),$$

called the elliptic integral of the second kind in Legendre's form;

$$\Pi(k, n, \phi) = \int_0^\phi \frac{d\phi}{(1 + n \sin^2 \phi)\sqrt{1 - k^2 \sin^2 \phi}} \; (0 < k < 1),$$

called the elliptic integral of the third kind in Legendre's form.

The number

$$K = \int_0^{\pi/2} \frac{d\phi}{\sqrt{1 - k^2 \sin^2 \phi}}$$

is called a complete elliptic integral of the first kind, and the number

$$E = \int_0^{\pi/2} \sqrt{1 - k^2 \sin^2 \phi} \cdot d\phi$$

is called a complete elliptic integral of the second kind.

In Jacobi's notation, $x = \sin \phi$, and the first two elliptic integral types become:

$$F(k, \phi) = \int_0^x \frac{dx}{\sqrt{(1 - x^2)(1 - k^2x^2)}},$$

with
$$K = \int_0^1 \frac{dx}{\sqrt{(1 - x^2)(1 - k^2x^2)}},$$

$$E(k, \phi) = \int_0^x \frac{\sqrt{1 - k^2x^2}}{\sqrt{1 - x^2}}\, dx,$$

with
$$E = \int_0^1 \frac{\sqrt{1 - k^2x^2}}{\sqrt{1 - x^2}}\, dx.$$

The constant k is known as the modulus of the integrals, and the number k' defined by $k^2 + k'^2 = 1 (0 < k' < 1)$ is called the complementary modulus.

Tables of the elliptic integrals have been published.

If we put

$$u = \int_0^x \frac{dx}{\sqrt{(1 - x^2)(1 - k^2x^2)}}, \quad (-1 < x < 1),$$

this equation defines u explicitly as a function of x. The **inverse function** x regarded as a function of u is called the sine amplitude of u and is written $x = \sin \text{am}\, u$ or $x = \text{sn}\, u$. Two other functions are defined by $\sqrt{1 - x^2} = \cos \text{am}\, u$ or $\text{cn}\, u$, and $\sqrt{1 - k^2x^2} = \Delta\, \text{am}\, u = \text{dn}\, u$.

These three functions are type forms of elliptic functions.

An elliptic function in general is defined as a single-valued doubly periodic **analytic function of a complex variable,** whose only singularities in the finite part of the plane are poles. Any elliptic function can be expressed in terms of certain standard types of elliptic functions, of which the main types are those of Jacobi and those of Weierstrass. The Jacobi elliptic functions $\text{sn}\, u$, $\text{cn}\, u$, $\text{dn}\, u$ have simple poles only, while the fundamental Weierstrass function $\wp(u)$ has double poles.

Elliptic functions are natural generalizations of the trigonometric functions and exponential functions, which are singly periodic functions. (L.L.S.)

ELLIPTIC PARABOLOID. **Paraboloids.**

ELLIPTIC POLARIZATION. **Polarized Light.**

ELONGATION. **Planetary Motions; Tension Test.**

ELUVIUM. General term for unconsolidated, residual **sediments.** (R.M.F.)

ELYTRON. The front wing of an **insect,** modified to form a leathery or rigid wing cover which folds above the body and conceals the hind wings at rest. They usually meet in a straight line down the middle of the back. Elytra are characteristic of the beetles and earwigs. They are sometimes short, sometimes cover the entire posterior part of the body, and are sometimes united to form an immovable shield. (A.W.L.)

EMBIIDINA. A small order of rare **insects** which live in nests and galleries of silk under objects lying on the ground. The few known species are found in warm regions, including the southwestern United States. (A.W.L.)

EMBOLISM. The plugging of a blood vessel by a clot, or embolus, carried from some other part of the circulatory system by the blood current. Air embolism is a condition, rarely seen, caused by the accidental introduction of air into the vascular system. Fat embolism is caused by oil or fat, and is sometimes seen following fractures of bones—the fat escaping from the bone marrow. Both air and fat embolism may result in death from the plugging of the capillaries of the brain or lung. Pulmonary embolism is the plugging of the pulmonary arteries by a blood clot. This is usually fatal, death resulting almost instantly. The condition may occur post-operatively, or with phlebitis or infection of some vein of the body, usually in the pelvis or legs. When such an infection occurs, a soft clot forms in the vein. If a piece of this clot should become dislodged, it goes, in the normal course of circulation, toward the lung, and thus may lodge in the pulmonary artery. If the clot is not of sufficient size to obstruct this artery, it travels along its branches within the lung proper. Wherever it lodges in the arterial system, the clot shuts off the circulation to the portion of the lung supplied by that particular branch. A small embolism is not necessarily fatal; the symptoms produced are in direct ratio to amount of lung tissue involved.

Cerebral embolism is caused by a clot lodging in a branch of one of the blood vessels of the brain. It may be associated with **apoplexy.** The symptoms produced depend on the part and amount of the brain involved, and on this depends whether death or paralysis, etc., result. This accident is known popularly as a "stroke." (R.S.M.)

EMBRITTLEMENT. Metals may become brittle under many different conditions. Ordinary **steel** and **wrought iron,** as well as **zinc alloys** and **magnesium alloys** suffer a reduction in **impact toughness** at subnormal temperatures. The reason for this form of brittleness is obscure. The effect is only temporary, full recovery of toughness occurring upon return to normal temperatures. Austenitic **stainless steels, brasses** and **bronzes, nickel alloys, aluminum alloys,** and **lead alloys** are not subject to severe embrittlement at low temperatures. Nickel additions to ordinary steels have a favorable effect.

Hydrogen embrittlement of iron and steel is caused by absorption of atomic hydrogen in **electroplating** processes or in **pickling** baths. After such exposure the normal toughness can usually be restored by prolonged aging or a short period of heating at a slightly elevated temperature, as in a steam bath.

Season cracking of high zinc brasses is a severe form of embrittlement resulting in cracking or disintegration. Somewhat similar forms of stress-corrosion cracking occur in many other metals and alloys. **Embrittlement of boiler plate** may be considered a special case.

Steels and ingot iron may be embrittled by any heat treatment that deposits films of either oxides or carbides in the grain boundaries. (See carbide embrittlement of **Stainless Steel.**)

Fatigue fractures are brittle in appearance but fatigue failures cannot proper'y be ascribed to a brittle condition of the metal. (R.H.H.)

EMBRITTLEMENT OF BOILER PLATE. This is the rarest of all **boiler** "diseases," yet it cannot be said to be so rare as to be unimportant. A serious feature of embrittlement is that when failure occurs it may come as a disastrous explosion, because embrittlement affects the drums and its presence is not detectable except on minute scrutiny. Embrittlement is attributed to the presence of a certain concentration of sodium hydroxide in the absence of inhibiting agents. The steel loses its toughness and cracks appear along the seams below the water line. They generally run from rivet to rivet, following the intercrystalline structure. In cases of embrittlement it has always been found that the feed water was high in sodium bicarbonate which broke down into sodium carbonate in the boiler and partially hydrolyzed. The reaction

$$Na_2CO_3 + HOH \rightarrow CO_2\uparrow + 2NaOH$$

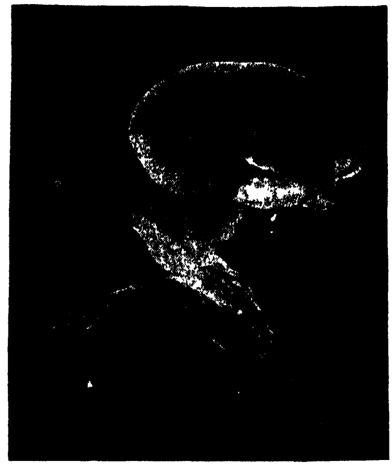
assumes considerable proportions at the elevated temperature of the boiler water. Prevention of embrittlement consists of reducing the causticity or adding an inhibiting agent such as sodium sulfate or phosphate. The A.S.M.E. recommendation consists of maintaining a ratio $\frac{\text{sodium sulfate}}{\text{sodium carbonate}}$ of 1 up to 150 lbs. gauge pressure, 2 up to 250 lbs., and 3 for 250 lbs. and over. No boilers meeting these ratios have experienced embrittlement. Recent developments have indicated that probably the more accurate expression for the inhibiting ratio is

$$\frac{\text{sodium sulfate} + \text{sodium carbonate}}{\text{sodium hydroxide}}.$$

Embrittlement or cracking of metal need not be feared in boilers provided this ratio is maintained in excess of 2. (F.T.M.)

EMBRYO. The developing individual between the union of the germ cells and the completion of the organs which characterize its body when it becomes a separate organism.

The term is difficult to limit because some development takes place after birth or hatching and in some species a considerable period of growth intervenes between the completion of the essential structures of the individual and its assumption of separate life. In the latter stage the organism is called a fetus if it is a



Human embryo at six weeks. *(Photo by Newton Mille)*

mammal, but this term is not applied to the similar period of birds and reptiles. For the embryo in botany, (see **Seed**). (A.W.L.)

EMBRYO SAC. Flower.

EMBRYOLOGY. The science which deals with the development of the individual from the union of the germ cells to the completion of its bodily structure Although the term **embryo** cannot be precisely limited, the science of embryology is concerned with all development prior to birth or hatching.

Development of the fertilized ovum begins with the process of **cleavage.** Following cleavage a process of gastrulation gives rise to two or three **germ layers** and from this point the development of specialized tissues and organs goes on by gradual steps, all based on the subdivision and differentiation of many cells.

The processes of change by which germ layers give rise to other structures are varied. In some cases masses of cells grow out in solid protuberances from an existing source. This process is called budding and is exemplified by the appearance of legs and other appendages on the surface of the body. Other structures are developed by the pushing in or out of layers of cells. If the new part pushes in the layer it is said to invaginate, and if it pushes out, to evaginate. Hollow organs may also be formed by the splitting of solid masses and parts may separate by splitting from such masses; either process is delamination. A good example of evagination is the pushing out of a blind sac from the embryonic pharynx of vertebrates to form the respiratory system, and invagination is illustrated by the pushing in of ectoderm to form the stomodaeum which becomes the oral cavity in part. The formation of the vertebrate excretory tubules as solid knots of tissue whose cavities arise by internal splitting is a case of delamination.

The details of development of any species or group of animals are complex. Vertebrate embryology has been worked out in great detail and is fairly uniform but the number of invertebrate forms is so great that their embryonic development cannot be concisely summarized.

In the vertebrates, once the germ layers are formed their further development is the formation of organs and tissues and in some species **extraembryonic membranes,** with the exception of the mesoderm. This layer gives rise to diffuse mesenchyme and its compact portions differentiate into three regions, the dorsal, intermediate, and lateral or ventral mesoderm. The first subdivides into two longitudinal series of metameric masses, the

mesodermal somites, flanking the middle line of the body where the notochord lies. This skeletal primordium is independently derived from the same source as the mesoderm. The lateral mesoderm splits to form an outer somatic layer associated with the body wall and an inner splanchnic layer which envelops the viscera. The split forms the coelom or body cavity. From this point the mesoderm, like the other germ layers, gives rise directly to organs of the body. The organs and systems developed from each embryonic tissue are listed under **germ layers.**

In the field of experimental embryology an effort has been made to learn of the controlling factors in development by subjecting embryos and ova to various unusual conditions. By exposure to chemical stimuli, unusual temperatures, radiation, and the effects of centrifuging, many abnormal results have been recorded. It is evident from these results that development, like the life of the organism, is conditioned by a delicate balance of environmental factors. The response of inherited potentialities to this balance in the development of normal organic structure links embryology very closely with the subject of **heredity.**

It has become evident that one of the important factors in the embryological differentiation is the interaction between parts of the embryo which have come close to each other in the course of development. This action is known as induction, the formation of a nervous system in the amphibian, for instance, being induced by the notochord. The term organizer is also used in this connection. (A.W.L.)

EMBRYONIC FISSION. The subdivision of a single **ovum** at some stage in its development into parts which give rise to complete **embryos.** Polyembryony.

As a result of this process a single egg of many insects (parasitic **Hymenoptera**) and of some **rotifers** develops into several or many individuals. (A.W.L.)

EMBRYOPHYTA. All plants which are not **thallophytes** are sometimes grouped together and called embryophytes. It is characteristic of these plants that for a time at least the developing plant or **embryo** remains dependent on the tissue of the **gametophyte.** The embryophyta are also generally characterized by the existence of an **archegonium,** a multicellular female sex organ in which the egg is contained. In the **angiosperms,** however, the reduction of the gametophyte has resulted in the loss of the archegonium.

The embryophyta include all the **Bryophytes, Pteridophytes,** and **Spermatophytes.** (R.M.W.)

EMERALD. This beautiful green variety of the mineral **beryl** has been known since ancient times and always prized as a gem, both because of its color and relative rarity. It is frequently cloudy or flawed, hence the expression "rare as an emerald without a flaw." The original source of emeralds seems to be the so-called Cleopatra's mines in Egypt, where in a range of low mountains about 15 miles from the Red Sea, they are found in **schists.** The quality of these emeralds is not high, but there is much evidence of considerable workings in a former period.

Although emeralds are found in the Urals and to some extent elsewhere the most important locality for emerald today is at Muso, Colombia, South America, about 75 miles northwest of Bogota. These mines are believed to be in part at least the source of the emeralds which Cortez and the Spanish conquistadores ruthlessly seized and which were believed for a long time to have come from Peru.

The word emerald is probably derived from the Persian. (E.S.C.S.)

EMETIC. A substance or **drug** that induces vomiting, either by direct action on the stomach or indirectly by action on the vomiting center in the brain. (R.S.M.)

EMETINE. A drug used in the treatment of amoebic **dysentery.** It is one of the alkaloids of **ipecac,** which is obtained from the dried roots of *Psychotria ipecacuanha* or *acuminata,* plants native to Brazil and Central America, but also cultivated in India. Emetine is used in the acute diarrhea stage of amoebiasis and is particularly useful in liver abscess due to entameba histolytica. It is given subcutaneously. (D.M.H.)

EMISSIVE POWER. Thermal Radiation.

EMMERMAN PROCESS. The Emmerman process, sometimes called the Direct **Person Process,** is a method of producing masks directly on photographic prints during processing for the purpose of obtaining good tone separation. The Emmerman process is an automatic masking method for use in projection printing. With this method, a silver mask is formed on paper by partially exposing a sheet of sensitive paper soaked with developer, on a glass plate on enlarger easel and allowing it to develop out fully before completing the exposure and developing the print in a tray.

The mask formed protects the shadow or dark areas of print so they do not become blocked up on the second exposure. The method is of particular value in making prints from negatives of subjects having an extreme brightness range, or an exposure scale too long for the print emulsion.

Three requirements are necessary for success with the Emmerman process. The developer must not fog or stain the wet paper while the mask is being made. The emulsion should not show reversal tendencies during the second exposure. It is advisable to use a paper grade one degree more contrasty than the negative normally requires. (S.M.T.)

EMPENNAGE. Tail; Airplane.

EMPHYSEMA. A structural change in the lungs, in which the smaller air sacs, the alveoli, are excessively distended at rest; they are permanently fixed in the inspiratory position thus reducing the vital capacity, or possible total exchange of air with inspiration and expiration. The **thorax** is altered in shape, and the patient with long-standing emphysema has a "barrel chest" which moves little, if at all, with respiration. **Cyanosis** and **dysponea** are common, and eventually **heart failure** occurs due to long-continued strain on the right side of the heart which pumps blood into the lungs.

Emphysema is the end picture in long-standing inflammatory and obstructive diseases of the lungs, in chronic **bronchitis** and bronchial **asthma,** and as a compensatory change when some parts of the lungs are not functioning. It is a common finding in individuals in certain occupations, being seen in glass-blowers and players of wind instruments. It is also a frequent finding in old age. (D.M.H.)

EMPIRICAL DATA. Empirical Equations.

EMPIRICAL EQUATIONS. A table of pairs of values of empirical or statistical data may be represented graphically by plotting the corresponding pairs of values as **rectangular coordinates** (or **polar coordinates**) of points in a plane and joining these points by a broken line or by a smooth curve.

The general problem in empirical equations is to find an equation which will represent the given data as accurately as possible. The general form of the required equation may be known in advance from theoretical considerations, but in other cases nothing may be known about the form of equation in advance.

If the given data are plotted as rectangular coordinates, and if the resulting points tend to lie along or very near a straight line, we may assume a linear law $y = mx + b$. To determine the coefficients m and b in this equation,

several methods are available: the method of average points, the method of average equations, and the method of least squares.

The straight-line law may be tested by use of the following theorem: If the variable x has constant first differences Δx (that is, differences between consecutive pairs of values of x), and y is a **linear function** of x, then y will have constant first differences Δy and conversely. If the given table of data has the first variable at equidistant intervals, and if the first differences of the second variable are found by calculation from the table to be constant or very nearly constant, we may assume a linear law.

In fitting a straight line to a set of empirical data by the method of average points, we first divide the set of points representing the data into two groups and find an average point for each group, i.e., one whose coordinates are averages of the respective coordinates; then we find the equation of the line through these two average points.

In the method of average equations, we substitute each pair of values of the empirical data in the assumed straight-line equation $y = mx + b$, and thus obtain as many so-called observation equations as there are pairs of corresponding values. We then divide these equations into two groups as nearly equal in number as possible. Then we add the equations of each group, thus obtaining two equations in m and b. Solving these two equations for m and b gives the required linear law $y = mx + b$.

The values of the coefficients obtained by the method of averages depend on the way the given points or the observational equations are grouped. In accurate scientific work, the values of the coefficients are found by the method of least squares; this method may be somewhat longer than the method of averages.

The method of least squares as applied to the linear law may be explained as follows: Assume the required equation to be of the form $y = mx + b$, where m and b are to be determined. Let (x_1, y_1), (x_2, y_2), $\cdots$, (x_n, y_n) be the given tabulated pairs of values of data. Let (x_k, y_k) be any pair of values of the data; then corresponding to the value of x_k of x the corresponding value of y as calculated from the equation is $mx_k + b$, but the tabular value of y is y_k. The difference between these two values of y, tabular and calculated, is $r_k = y_k - (mx_k + b)$, which is called the residual of the point (x_k, y_k) with respect to the line. Corresponding to the n points there are n residuals. Geometrically they represent the vertical distance between each point and the required line.

Let us form the sum of the squares of these residuals: $r_1^2 + r_2^2 + \cdots + r_n^2$, which is represented more briefly by the symbol Σr^2.

The basic principle of the method of least squares in this case may be stated thus: The values of m and b determined by the method of least squares are those that make the sum of the squares of the residuals Σr^2 as small as possible.

It is found that the values of m and b that make Σr^2 a minimum are determined by the equations $\Sigma y = m\Sigma x + bm$, $\Sigma xy = m\Sigma x^2 + b\Sigma x$. To form these equations, we may proceed as follows: We write down two sets of equations. The equations of the first set are formed by substituting the given pairs of values of x and y in the equation $y = mx + b$. The equations of the second set are formed by multiplying each equation of the first set by the coefficient of m in it. We obtain thus the following sets of equations:

$$\begin{array}{ll} y_1 = mx_1 + b & x_1y_1 = mx_1^2 + bx_1 \\ y_2 = mx_2 + b & x_2y_2 = mx_2^2 + bx_2 \\ y_3 = mx_3 + b & x_3y_3 = mx_3^2 + bx_3 \\ \text{etc.} & \text{etc.} \end{array}$$

If we add the members of the equations in each of the two sets, we obtain two equations in m and b, which can be solved for these two unknowns, and these values put in the form $y = mx + b$ give the required equation in the sense of least squares.

If the graph of the given data does not indicate a linear law, or if the test of the data by first differences does not show a linear law, it may be that the data may be fitted by a quadratic law. This may be tested as follows:

If a variable x has constant first differences, and if the related variable y is a **quadratic function** of x, then y will have constant second differences $\Delta^2 y$ (that is, successive differences of the first differences Δy), and vice versa. Hence, if $\Delta^2 y$ is found constant or nearly so, we may assume a quadratic law $y = ax^2 + bx + c$.

If we decide that the given data may be fitted by a quadratic (or parabolic) law $y = ax^2 + bx + c$, we may determine the coefficients a, b, c by the method of averages or by the method of least squares.

In the method of average points, we divide the data into three groups nearly equal in number, and find three average points, one for each group. Substituting the coordinates of these three average points in the above equation, we obtain three equations with three unknowns, which may be solved for a, b, c.

By the method of average equations, we substitute the given data in the assumed equation, divide the resulting equations into three groups nearly equal in number, add the equations of each group, then solve the resulting three equations for a, b and c.

In the method of least squares for the quadratic law, we proceed as follows: Form three sets of equations, the first set being the equations obtained by substituting the given data in the general parabolic law equation $y = ax^2 + bx + c$; the second set is obtained by multiplying each equation of the first set by the coefficient of b in it, and the third set by multiplying each equation of the first set by the coefficient of a in it. Add the corresponding members of each set of equations, obtaining thus three new equations in three unknowns a, b, c. Solving these equations for a, b and c gives the coefficients of the required equation.

If a linear or quadratic law does not fit the given data, we may try plotting the data on **logarithmic paper.** If the resulting points tend to lie on a straight line, an equation of the power-law type: $y = ax^n$ is indicated.

For, if we assume the law $y = ax^n$, and take logarithms, we obtain $\log y = \log a + n \log x$. Put $\log y = Y$, $\log a = A$, $\log x = X$, and the equation becomes $Y = A + nX$, a linear law, giving a straight-line graph. If X and Y (i.e., $\log x$ and $\log y$) are plotted on ordinary squared paper, or if x and y are plotted on logarithmic paper, we should get a straight line. The equation of this straight line may be found by one of the previous methods for the linear law, obtaining A and n. Then a will be the anti-logarithm of A, and the coefficients a and n are known, which may then be substituted in $y = ax^n$.

If, when plotted on logarithmic paper, the data does not give a straight line, we may try plotting it on **semi-logarithmic paper**; if these points tend to lie on a straight line, an equation of exponential type: $y = ae^{bx}$ is indicated.

For, if we assume the equation $y = ae^{bx}$, and take (common) logarithms, we get $\log_{10} y = \log_{10} a + bx \log_{10} e$. Put $\log_{10} y = Y$, $\log_{10} a = A$, $b \log_{10} e = m$, and the preceding equation becomes $Y = A + mx$, a linear law. Hence, if x and Y $(= \log y)$ are plotted on ordinary cross-section paper, or if x and y are plotted on semi-logarithmic paper, we should obtain a straight line The equations of this straight line can be found by one of the previous methods for the linear law, giving A and m Then a may be found as the anti-logarithm of A, and

b may be found from $m/\log_{10} e$. These values substituted in $y = ae^{bx}$ give the required equation.

It may be in some cases that a polynomial law $y = a + bx + cx^2 + dx^3 + \cdots$ will fit the data better than any of the preceding types; the equation of lowest degree is desired. It is treated similarly to the quadratic law.

Other forms of equations are sometimes useful. The following forms may be reduced to the straight-line law by suitable transformations.

The law $y = a + bx^2$ may be reduced to a straight-line law by the substitution $x^2 = X$, $y = Y$.

The law $y = a + \frac{b}{x}$ reduces to the straight-line law by the substitution $1/x = X$, $y = Y$.

The law $y = \frac{x}{ax + b}$ can be written $\frac{x}{y} = ax + b$, so that if we put $x/y = Y$ and $x = X$, the equation becomes $Y = aX + b$, a straight-line law. (L.L.S.)

EMPIRICAL PROBABILITY. Probability.

EMPYEMA. A collection of pus in any cavity or organ of the body. The term is generally used in describing a collection of pus in the **pleural** cavity. This is a common complication of **pneumonia.** In pneumonia a simple **pleurisy** with fluid develops which later may become infected, accompanied by formation of pus. The treatment is surgical. Empyema of the gall bladder may occur when there is obstruction to the cystic duct in the presence of infection of the organ. (R.S.M.)

EMU, EMEU. Aves, Casuariiformes. Large, flightless herbivorous birds (**Aves**) of Australia. They have very small wings but are fleet of foot.

On some islands of the Australian region the emeus have been exterminated and in Australia itself they are said to be restricted to the wild interior and to be scarcer year by year. The best-known species is *Dromaeus novae-hollandiae*. (A.W.L.)

EMULSION. Colloids.

ENAMEL. Ceramics; Pigments, Paints, Varnishes; Tooth.

ENANTIOMORPHISM. Isomerism.

ENARGITE. A mineral sulfosalt composed of copper, arsenic and antimony, $Cu_3(As, Sb)S_4$. Crystallizes in the orthorhombic system. Hardness, 3; specific gravity, 4.451; color, gray to black with metallic luster. From the Greek, meaning **distinct** cleavage. (R.M.F.)

ENCEPHALITIS. Inflammation of the brain. The causative agents are injury, infection, or the action of toxic substances on the brain tissue. Epidemic encephalitis is considered elsewhere as a separate disease.

Encephalitis may complicate diseases such as **syphilis, malaria, measles, mumps, influenza, typhus,** and many others. It may be caused by metals, (e.g., lead encephalitis), carbon monoxide, caisson disease, fracture of the skull with injury to the brain, etc.

The symptoms may occur suddenly or gradually with lethargy, fever, headache and stiffness of the neck. Often the temperature is excessively high. **Paralysis,** deafness and other nervous manifestations are frequently present.

The mortality is high in recognized cases, although many cases are not diagnosed, especially when of lesser degree. Aftereffects such as deafness, **epilepsy, dementia,** changes in personality, etc., are found in many cases that survive. (R.S.M., D.M.H.)

END AREA METHOD. Earthwork.

END MILL. Milling.

END POST. Bridge.

END STIFFNER. Bridge.

ENDEMIC. A term used in reference to a disease that is prevalent in a particular locality, recurring frequently but affecting only a small part of the population at one time. (See **Epidemic.**) (D.M.H.)

ENDIVE. *Cichorium Endivia.* Composite Family.

ENDOCARDITIS. Inflammation of the tissue that lines the various cavities of the **heart,** and of the heart valves. The disease may occur as part of a symptom complex of **rheumatic fever,** or as a complication of many acute infections, such as septicemia due to the *Staphylococcus, Streptococcus, Pneumococcus, Gonococcus,* or *Influenza bacillus*. Endocarditis is a complication that usually results fatally.

Subacute bacterial endocarditis is a form of the disease usually caused by the streptococcus viridans. It occurs only on valves previously damaged by rheumatic disease or deformed by congenital anomalies. The disease was formerly fatal within two years, but recent work with **penicillin** suggests that many cases may be cured by large doses of this drug. (D.M.H.)

ENDOCARP. Fruit.

ENDOCRINE GLAND. A gland whose secretion is carried by the blood stream. Also called ductless glands. These organs produce substances known as **hormones** which condition the action and development of other parts of the body either by activation or by inhibition.

The principal ductless glands of the vertebrates are the thyroid, parathyroids, pituitary, adrenal or suprarenal, ovary and testis, and pancreas; the thymus and pineal were at one time classified as endocrine glands, but modern research has so far failed to substantiate this concept. The first two develop as outgrowths of the **pharynx.** These endodermal parts lose their connections with the pharynx and become associated with mesodermal tissue in the adult. The pituitary gland is made up of an anterior lobe derived from an ingrowth of ectoderm and a posterior lobe derived from the brain. In the adult it is connected with the under side of the brain. The adrenals lie near the kidneys or in contact with them and consist of an outer cortex and an inner medulla, both endocrine in function. The cortex arises from the lining of the body cavity and the medulla from cells of the sympathetic nervous system. The ovary and testis are developed from mesoderm. Although their primary function is the production of germ cells, they also produce hormones in some of their parts. The pancreas is a digestive gland derived from and connected with the intestine. Among its digestive cells are small islets of Langerhans which have no connection with its duct but which produce a hormone.

The action of these glands is considered under **Hormone.** (A.W.L.)

ENDODERM. Germ Layers.

ENDOGENETIC. As used by geologists to denote processes originating within the earth. (R.M.F.)

ENDOMORPHISM. That phase of contact **metamorphism** which takes place in the intrusive **magma** rather than in the walls of the rock mass which it invades. (R.M.F.)

ENDOPHRAGMAL SKELETON. An internal framework found in some **crustaceans.** It is made up of **apodemes** derived from the exoskeleton. (A.W.L.)

ENDOPODITE. Biramous Appendage.

ENDOPTERYGOTA. Insects whose wings are concealed beneath the integument of the **larva** during development. Such insects have complete metamorphosis, hence this term is synonymous with **Holometabola.** (A.W.L.)

ENDOSKELETON. **Skeletal System.**

ENDOSPERM. **Flower.**

ENDOSTERNITE. A skeletal plate lying beneath the anterior part of the alimentary tract in some **crustaceans.** Mesodermal (see **Germ Layers**) in origin. (A.W.L.)

ENDOSTYLE. A groove lying in the median line of the ventral wall of the **pharynx** in the **tunicates,** lancelets (**Amphioxus**), and larval lampreys (**Cyclostomata**). It is ciliated (see **Cilium**) and secretes mucus. Food particles swept into the pharynx are caught by the mucus and carried forward to peripharyngeal grooves which run around the pharynx to a dorsal median hyperbranchial groove. In this groove the food is carried to the intestine.

The thyroid gland of vertebrates evolved from the endostyle. (A.W.L.)

ENDOTHELIUM. The delicate lining of the organs of **circulation.** It is one cell in thickness and is continuous throughout the closed passages with the exception of the **sinusoids.** The walls of capillaries are made up of little more than the endothelium. (A.W.L.)

ENDOTHERMIC REACTION. **Thermochemistry.**

ENDURANCE, AIRPLANE FLIGHT. **Range and Endurance; Airplane.**

ENDURANCE LIMIT. **Fatigue.**

ENERGY Energy is probably to be regarded as the most fundamental of all physical entities, though within the past few years our concepts relating to it have undergone quite revolutionary changes.

From the elementary and older point of view, energy is thought of as an intangible something transferred to bodies of matter when **work** is done upon them, and delivered up by such bodies whenever they do work upon other bodies. Thus, let a free body be acted upon by a steady force of 6 lbs. until it has moved from rest a distance of 100 ft. in the direction of the force. The work thereby done upon the body is 600 **foot-pounds,** and since the moving mass is now capable of doing 600 foot-pounds of work upon other bodies by collision or otherwise, we think of this 600 foot-pounds as something which has been transferred and conserved throughout the process.

Considerations of this kind have led, in the past, to regarding energy primarily as that which is thus communicated and conserved whenever work is done by one body upon another. But in the nineteenth century, Joule and others discovered the equivalence of **heat** and energy. And when it was established that **light** is a form of energy traveling through space apparently independent of any matter, it became necessary either to construct a dynamics for light and to invent an **ether** in which to carry on its operations, or else to accept energy, at least radiant energy, as having an objective existence of its own, coordinate with that of matter itself.

In the measurement of energy, we still adhere to the elementary concept and utilize its familiar relationship with the dynamic magnitude, work. We even express energy in work units; though there is todav no more logical reason for doing so than for adhering to the old water-temperature **calorie** in measuring heat. Thus the practical energy units are, in pure physics, the **erg** or centimeter-dyne, in engineering, the foot-pound.

Whenever energy is obviously associated with the motion of masses of matter—the form in which we sense its existence most readily—it is called **kinetic energy.** But since work may be done in such a way as not to affect the motion of matter, but to alter its situation or condition in other ways (as when a battery is charged or a clock wound), we must also recognize the existence of latent or **potential energy.** Much of the activity going on in the material world involves the continual transformation of energy from one of these states to the other.

Early experimenters observed that when a **machine** is so constructed as to operate with negligible friction, the work done by the machine is equal to that done upon it. Thus, if a weight of 20 lbs. is lifted 7 ft. by means of a single movable pulley, the operator, though obliged perhaps to exert only 10 lbs. of force on a cord, must draw that cord upward 14 ft. In each case the work done is 140 foot-pounds. The extension of this principle to a multitude of complex cases finally led to the doctrine of conservation of energy, recognized in various aspects by different physicists toward the middle of the nineteenth century. This doctrine, in concise form, states that the total quantity of energy in existence remains unaltered throughout all the changes which take place in the material universe. It is thus analogous to the earlier doctrine of the conservation of **mass.**

Modern research in **relativity** and atomic physics has cast some doubt upon the literal truth of both of these doctrines. Einstein, in studying the relativistic connection between matter and energy, arrived at the conclusion that energy, like mass, possesses inertia and gravitational attraction, in such degree as to make the unit of energy equivalent to $1/c^2$ units of mass (in which c is the speed of light); so that 1 gram of matter has the same inertia and gravitational attraction as c^2 **ergs,** or 8.986×10^{13} joules, of energy. Subsequent observation has supported not only this view, but the further theory that in certain circumstances matter may be actually converted into energy, and perhaps energy into matter, in the same ratio. Thus if the sun emits its radiant energy without drawing upon any source of supply other than that arising from the transformation of its mass, the Einstein proper energy principle leads to the conclusion that its mass must be diminishing at the rate of some 4,600,000 tons per sec. If all the **stars** are likewise sacrificing their mass to keep up their radiation output, and if this energy is not somewhere re-created into matter, it is clear that the conservation doctrine is not universally valid, unless applied to the totality of both matter and energy together as a single entity. (See **Available Energy.**) (L.D.W.)

ENERGY LEVELS. **Quantum Theory.**

ENERGY LOAD. **Energy.**

ENGINE. In common usage, the term engine is used widely for devices which produce motion. In stricter technical sense, an engine is said to transform energy, especially heat energy, into mechanical work. Among the prime movers, those in which the power originates in a piston and cylinder are classed as engines, while those with purely rotative motion are known as turbines. (See **Diesel Engine, Otto Engine,** and **Steam Engine.**) (F.T.M.)

ENGINE LATHE. **Lathe.**

ENGINE PERFORMANCE, INTERNAL COMBUSTION. The performance of any prime mover is of interest to the owner, operator, and designer, as is also the variation in performance created by changes in mode of operation. While many features of prime-mover action might be designated as performance, the

items usually selected are (1) **power** output, (2) **thermal efficiency,** (3) speed, usually rotative.

As internal combustion engine performance is influenced by more independent performance factors than any other commercial prime movers, internal combustion performance factors are chosen for description here.

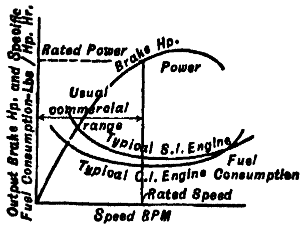


Fig. 1. Full throttle performance.

The output of such an engine is its "shaft horsepower," sometimes called brake horsepower because it used to be frequently measured by a brake-type of absorption **dynamometer.** Since the purpose of obtaining and using an engine is for its power, the brake hp. is of first concern in any event. The operating expense of an engine consists mainly of the cost of fuel; hence fuel consumption (i.e., quantity per unit time at a specified output), specific fuel consumption (lb. per brake hp.-hr.), or thermal efficiency is important, it being the measure of the direct cost of producing power. Rotative speed, say rpm, affects size and weight of the engine; also, its application to specific driven machinery, since direct drive, if possible, is usually simplest and best.

The internal combustion engine combines fuel and air in combustion for the production of a gas pressure against the piston. A basic factor of performance is, therefore, atmospheric air. But this may vary greatly both in temperature and density, especially in the aeronautical field. To combat loss of power due to diminishing atmospheric density at altitudes, airplane engines are often provided with **superchargers** to compress that air toward sea-level density. However, should this compression also be applied to sea-level air, the resulting charge would be so powerful as to damage the engine by overstraining and overheating cylinders, pistons, bearings, etc. It is necessary to throttle the intake so that the cylinder **mean effective pressure** will be limited to a safe value. This adds manifold pressure to other factors affecting power output.

Because friction and cooling heat losses tend to remain constant though output varies, thermal efficiency is not constant but decreases at part capacity. Correspondingly, the specific fuel consumption increases. This variation (with constant rpm) is visualized in Fig. 2, part load being carried by throttling the inlet so as to reduce the fuel admitted per cycle. If the inlet is unrestricted, but the output is varied by adjustments of the connected load, so that speed increases, the output will first rise (as shown in Fig. 1), then decrease as a speed is reached where **volumetric efficiency** is decreasing more rapidly than number of power cycles increase. Likewise, fuel consumption is increased at slow speeds because more heat is transferred to the cooling system as a result of the relatively longer time the hot gases are exposed to the cylinder walls. Again, it is increased at high speeds because of increasing mechanical friction. Some intermediate speed will exhibit an optimum combination of cooling and friction, producing minimum **fuel consumption** and **maximum thermal efficiency.**

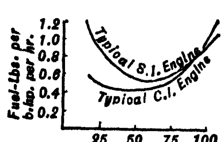

Fig. 2. Constant speed performance.

Ruggedness, reliability, and long life are features that cannot be expressed by factors shown in these figures. High speeds can result in damaging centrifugal and reciprocating stresses. Excessive supercharging of engine cylinders forces quantities of fuel and air into the combustion chamber, where excessive pressures and temperatures can be produced.

Cylinder mean effective pressure, or the hypothetical *Brake Mean Effective Pressure,* as has been mentioned, is controlled by throttling the induction system. The same power may be produced by various combinations of induction manifold pressure and rotative speed lying between the extremes of maximum allowable mean effective pressure with low speed and maximum speed with low mean effective pressure.

Fig. 3 shows a typical altitude-power curve involving rpm and manifold pressure as variables. At full throttle the power decreases uniformly with increase of altitude. The critical altitude is the maximum altitude attainable with a given rpm and manifold pressure combination. Full throttle operation is implied. For example, the critical altitude shown by Fig. 3 for normal rpm (2500) is 6800′. Thus the curve of the limit of full-throttle operation is also one of critical altitude vs. rpm. At superior altitudes power falls off. The lines showing power vs. altitude at constant manifold pressure and rpm rise slightly since constant manifold pressure on the inlet, and decreasing atmospheric pressure on the exhaust, tend to increase mean effective pressure; also, lower atmospheric temperature at higher altitudes has some tendency to increase volumetric efficiency. If the air intake is located so that it obtains some air **ram** there will be an increase of critical altitude. (F.T.M.)

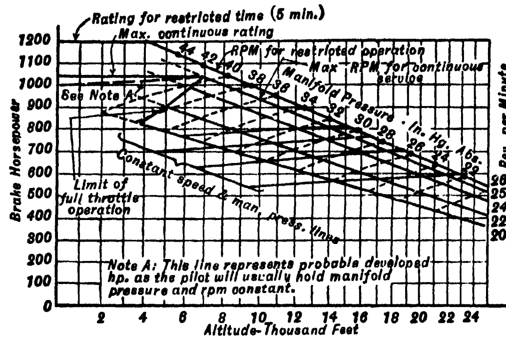

Fig. 3. Aircraft engine calibration curves.

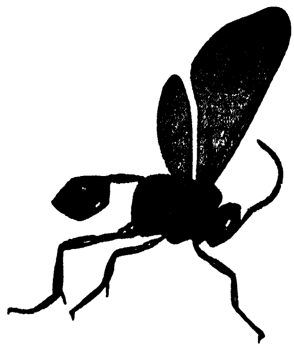
ENGINEERING STATISTICS. **Industrial Statistics.**

ENGINES, AIRCRAFT. **Aeronautical Engines.**

ENOL. **Tautomerism.**

ENRICHMENT. Also "secondary enrichment." The term applied by students of ore deposits to the natural processes by which the lower levels of an ore deposit are enriched at the expense of the upper levels, or the original protore. Particularly applied to **lodes** in which the **sulfide** ores have been concentrated by the leaching of the upper levels of the **vein** and redeposition below the **groundwater** table. Important ore minerals belonging to this type are **chalcocite** and **argentite.** (R.M.F.)

ENSIGN FLY. Insecta, Hymenoptera. Small parasitic **insects** whose abdomen is elevated on a slender stalk above the thorax. It has been likened to a flag and gives the common name to the group. The en-



Ensign fly.

sign flies make up the family Evaniidae. In all species whose habits are known the larvae are parasitic in the eggs of cockroaches. (A.W.L.)

ENSILAGE. Corn.

ENSTATITE. The mineral enstatite is an **orthorhombic pyroxene**, rarely in distinct crystals, usually found as fibrous or lamellar masses or perhaps compact. It has one easy cleavage parallel to the prism; brittle with uneven fracture; hardness 5.5; specific gravity 3.1–3.3; luster pearly to vitreous, sometimes somewhat metallic in **bronzite**, a variety of enstatite carrying up to 15% ferrous oxide FeO. Color grayish to greenish or yellowish-white, green and brown. Chemically enstatite is a silicate of magnesium, $MgSiO_3$. It occurs in igneous rocks which are high in magnesium content, like **gabbros, diorites, pyroxenites,** etc., and less commonly in metamorphic rocks. Meteorites of both the stony and metallic types have been shown to contain enstatite. It has been found at many places in Europe, Czechoslovakia, Austria, Bavaria, Germany, Norway and South Africa. In the United States it occurs in Putnam and St. Lawrence Counties, New York; Lancaster County, Pennsylvania; Jackson County, North Carolina, and near Baltimore, Maryland. The name enstatite is derived from the Greek word meaning *opponent,* in reference to its refractory nature; it is almost infusible. (E.S.C.S.)

ENTERIC CAVITY, ENTERON. The digestive cavity. This cavity forms by the splitting or invagination of the inner **germ layer** early in embryonic (see **Embryology**) development and persists as a sac with one opening to the exterior in the **coelenterates** and flatworms. In this form it is also called the archenteron.

In animals with a tubular alimentary tract the enteric cavity becomes the primitive gut. Its endodermal lining becomes the glandular digestive tissue and gives rise to large glandular masses in some species, and in the terrestrial vertebrates also produces the respiratory system.

The tubular enteric cavity is supplemented by invaginated tubes of ectoderm at each end, the **stomodaeum and proctodaeum.** (A.W.L.)

ENTERITIS. Any inflammation of the small intestine, usually accompanied by fever, pain in the abdomen, **diarrhea** and other constitutional symptoms. (R.S.M.)

ENTEROCOELA. Animals whose bodies contain no other cavity than that used for digestion. **Coelenterates, ctenophores, flatworms, nemerteans, roundworms** and **rotifers.** (A.W.L.)

ENTEROPNEUSTA. Hemichordata.

ENTEROSTOMY. An artificial opening made surgically in the intestine so that it may communicate with the outside through the abdominal wall or communicate with another portion of the gastrointestinal tract. It may be temporary or permanent in character. (R.S.M.)

ENTEROZOA. Animals which have a digestive cavity, the **enteric cavity.** All animals but the **protozoans** and **sponges.** (A.W.L.)

ENTHALPY. The enthalpy of a substance is defined as the sum of its internal and potential energy above some datum. Thus $h = u + pv$. A theoretical datum would be absolute zero of temperature. However, enthalpy tables for the practical use of engineers have, for the zero datum of u, a temperature of 32° F. for steam, −40° F. for refrigerants, and 80° F. for gases.

The incremental change of enthalpy for all gas processes is $c_p\,dt$ where c_p is the isobaric specific heat. This is not true of vapor processes unless a high degree of superheat exists. (F.T.M.)

ENTLADUNGSSTRAHLEN. This German term (meaning "discharge rays"), used by Wiedemann and adopted into English, refers to certain types of radiation emitted by electric sparks, apparently in the extreme **ultra-violet** range. At atmospheric pressure, short condenser sparks give radiation of wavelength approximately 900 **angstroms,** while for long sparks from an induction coil the wavelength is shorter, probably between 400 angstroms and 900 angstroms. At reduced pressures the wavelength is still shorter. These radiations produce ionization in the air and are strongly absorbed by **fluorite,** which is thereby rendered thermoluminescent (an effect called radio-thermoluminescence; see **Luminescence**). Experiments on the reflection of *Entladungsstrahlen* indicate their **total reflection** by glass or by celluloid with a critical angle of about 82°, which corresponds to a refractive index of 0.99. Work with these rays is difficult, as elsewhere in the far ultraviolet, on account of the absence of simple means of detecting them and because of their rapid absorption in air. (L.D.W.)

ENTOMOLOGY. The science that deals with all facts pertaining to **insects.** Because of the large number of insect species and their frequent economic importance the principal divisions of the science have been systematic entomology and economic entomology. Classification is difficult and intricate, and demands the constant service of specialists. The economic field is of such importance, especially to agriculture, that the national and state governments maintain organizations for the scientific study of insects which also assist in their control. (See **Insect Pests.**)

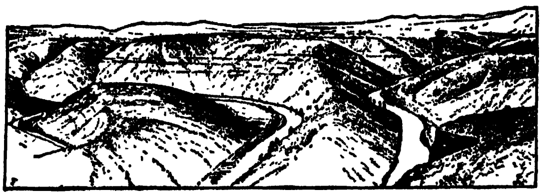
Although entomologists may specialize in insect **morphology** or physiology, work of this type is less extensive than more practical studies and is of more general biological interest, hence it takes its place largely in the subsidiary sciences of general biology. (A.W.L.)

ENTOMOSTRACA. A division of the class **Crustacea** formerly used to include all but the subclass **Malacostraca.** (A.W.L.)

ENTOPROCTA. A class of **Bryozoa.**

ENTRENCHED (or INCISED) MEANDER. A river valley which has a distinctly meandering old-age pattern (longitudinal profile), and a V-shaped or canyon-shaped, youthful transverse profile. The meandering course of the river is inherited from the time when it flowed at, or close to, **base level,** that is on a relatively flat surface. Subsequent uplift of the region quickens the flow of the stream, hence its downcutting power, without necessarily altering its inherited mean-

dering course. Entrenched meanders are therefore physiographic evidence of the rejuvenation of the erosive power of an old-age stream. Entrenched meanders



A rejuvenated region showing entrenched meanders. Yakima Canyon, Washington. (*Hobbs, after G. O. Smith.*)

may suggest the first stage in a new **cycle of erosion,** but usually imply an interruption in the normal cycle due to relatively sudden uplift of the region before the entire area has been reduced to a **peneplain.** (R.M.F.)

ENTROPY. The physical interpretation of this thermodynamic term, introduced by Clausius, has proved somewhat difficult.

In the mathematical treatment of thermodynamic processes there occurs very often a quantity, now relating energy to absolute temperature, now associated with the **probability** of a given distribution of **momentum** among molecules, and again expressing the degree in which the energy of a system has ceased to be **available energy.** Its mathematical form suggests that these are all aspects of a single physical magnitude. Application of the "second law" of **thermodynamics** leads to the conclusion that if any physical system is left to itself and allowed to distribute its energy in its own way, it always does so in a manner such that this quantity, called "entropy," increases; while at the same time the available energy of the system diminishes. This law applies to the universe as a whole, hence the proposition that the total entropy increases as time goes on. An interesting conclusion as to entropy in the vicinity of absolute zero is expressed by the Nernst heat theorem; viz., that all physical and chemical changes in this region take place at constant entropy. Any process during which there is no change of entropy is said to be "isentropic." This is true, for example, of an **adiabatic process** in which there is no dissipation of energy, i.e., one which is also a **reversible process.** In thermodynamic discussions entropy is commonly classed, along with temperature, pressure, and volume, as one of the variables defining the state of a body, and is often graphed as such on thermodynamic diagrams. (L.D.W.)

ENVELOPES. If the curves of a family are tangent to the same curve or group of curves, the name envelope of the family is applied to the curve or group of curves.

The envelope of the family of curves $f(x, y, \alpha) = 0$, where α is the variable parameter of the family, is given by the pair of equations:

$$f(x, y, \alpha) = 0 \quad \text{and} \quad \frac{\partial f}{\partial \alpha} = f_\alpha\ (x, y, \alpha) = 0.$$

We may regard these as giving **parametric equations** of the envelope, or we may eliminate α between the two equations. (L.L.S.)

ENVIRONMENT. The assemblage of material factors and conditions surrounding the living organism and its component parts.

Environment includes both external and internal factors. In the external environment inanimate objects and the forces associated with them constitute the physical environment, and the living things and their derivatives with which the animal may be associated constitute its organic environment. Within its body it maintains an organization which constitutes an internal environment to which all of its parts respond directly, whether or not they also have external contacts. (See **Ecology, Distribution** and **Habitat.**) (A.W.L.)

ENZYME. An organic **catalyst,** i.e., a substance produced by a living organism that conditions some chemical action within the body and is not permanently altered in the process. The inorganic catalysts of chemistry and the enzymes of biology are similar in many ways. Both bring about specific chemical changes at a rate depending on the amount of active material present, and both influence the transformation of many times their own weight of material. Enzymes are more complex than inorganic catalysts, although their composition is not definitely known. They are regarded as disperse **colloids** in combination with **proteins.**

Enzymes have been classified in three principal groups: 1. Hydrolytic enzymes. 2. Oxidases, reductases, and zymases. 3. Catalase. A large number have been studied in some detail.

The hydrolytic enzymes facilitate the simplification of organic compounds by **hydrolysis** and are important in digestion, in the coagulation of **blood,** and in the formation of waste products and other substances in the body. Their action (hydrolysis) is the splitting of molecules of the compound affected in association with molecules of water to form compounds of simpler molecular structure, in some cases as one step in a series of similar enzymatic actions. For example, **starch** is hydrolyzed by the enzyme ptyalin in the saliva to produce maltose, and this **sugar** is hydrolyzed by maltase in the small intestine to form the simple sugar, **glucose,** which can be absorbed into the body.

Some of these enzymes act on **fats** and allied substances and are called esterases, some act on starches and sugars and are called carbohydrases, and some act on **proteins** and related compounds and are grouped as proteases, amidases, etc.

The oxidases and related enzymes bring about oxidation, reduction, and similar actions. Among them tyrosinase acts on the substance tyrosine, an **amino acid,** to produce the pigments known as melanins, while glycolase acts on sugars to produce lactic acid, and zymase, also acting on sugars, produces **alcohol** and **carbon dioxide.**

The enzyme catalase breaks down **hydrogen peroxide** into water and oxygen.

Enough is known of the specific enzymes and their action to show that they play an extensive part in the chemical processes of the body. It is entirely probable that many processes not clearly understood at present are enzymatic in nature, and that even the processes of reproduction and heredity are fundamentally of this kind. The literature on the subject records many established and many conjectural processes.

Enzymes are also used in various manufacturing processes, including the preparation of fibers and fabrics in the weaving industry, the removal of hair and subcutaneous tissue from hides preparatory to tanning, several stages of brewing, cheese making, and a number of processes in less familiar fields.

Because the enzymes are associated with colloidal substances they are very difficult to isolate and purify; nevertheless pepsin, urease and some others have been isolated in the crystalline state. Enzymes are very unstable substances and often lose their catalytic ability without the concomitant loss of their other characteristics (denaturation). They are as a rule inactive at 0° C., increase in activity with rise in temperature, and are destroyed at high temperatures. There is an optimum **hydrogen ion** concentration range for each enzyme. Many of them require activators, coenzymes or accelerators for their action and are inhibited in their catalytic activity by minute traces of certain sub-

stances such as **hydrogen cyanide.** The following is a list of the more important enzymes and the reactions they catalyze:

ENZYME	REACTION
Lipase	Hydrolysis of **fats**
Diastase	Hydrolysis of **starch**
Maltase	Hydrolysis of maltose and alpha **glucosides**
Emulsin	Hydrolysis of beta **glucosides**
Lactase	Hydrolysis of **lactose**
Pepsin	Hydrolysis of **proteins** in acid medium to peptones
Trypsin	Hydrolysis of **proteins** to amino acids
Urease	Hydrolysis of **urea**
Rennin	Coagulation of **casein** in the presence of calcium
Tyrosinase	Oxidation of **tyrosine**
Luciferase	Oxidation of luciferin to produce light (fire-fly)
Catalase	Decomposition of **hydrogen peroxide**
Zymase	Alcoholic **fermentation**
Invertase	Inversion of cane **sugar.**

(R.K.S., A.W.L.)

EOCENE. A subdivision of the **Tertiary** of the geologic time-scale. Type locality, near Paris, France. Term first proposed by Lyell in 1832. The Eocene began approximately 60 million years ago and lasted for about 20–30 million years. The greatest thickness of formations of this period occur in Wyoming. The principal areas of deposition in the United States are: 1. The unconsolidated marine gravels, **glauconite** sands and clays which overlap the Cretaceous marine sediments of the Atlantic Border. 2. The marine limestones, terrestrial sandstones and **lignites** of the Gulf Coast. 3. The marine sediments of the Pacific Coast. 4. The terrestrial intermontane deposits of the Western interior. The plants of this period suggest world-wide warm climate. The fossil plants include many of the modern genera, such as the beeches, dogwoods, walnuts, maples and elms. Fossil vertebrate skeletons show that the mammals are now dominant, although many of the existing orders of reptiles and birds also lived at this time. The mammalian fauna may be divided into two principal groups: 1. The archaic types which did not survive the Eocene. 2. The progenitors of the modern mammals, including the ancestors of the camels, pigs, horses, rats, and primitive monkeys. The principal surviving archaic forms are the creodonts (primitive flesh-eaters), uintatheria (hippopotamus-like forms), and zeuglodons (marine mammals). The mineral resources of this period are described under the Tertiary. (R.M.F.)

EOLITHS (Kentish). Paleontology of Man.

EOSIN. Dyes.

EOSPHORITE Childrenite.

EÖTVÖS BALANCE. Gravitation and Gravity.

EOZOÖN. The name of a "problematical" **fossil** in the Grenville limestone (marble) of Canada. Since the Grenville formation represents one of the oldest known **sedimentary** formations, Eozoön has aroused considerable discussion among geologists and **paleontologists.** Originally described as a giant **foraminifera,** it is now known to be of inorganic origin, probably the result of **contact metamorphism** between the interbedded basic lavas (now **serpentine**) and the limestones. The term Eozoön is derived from the Greek, meaning dawn animal. (R.M.F.)

EPEIROGENY. Signifying broad and relatively widespread or continental uplift as compared with mountain building or **Orogeny.** (R.M.F.)

EPHEDRA. Gymnosperms.

EPHEDRINE. Drugs and Alkaloids.

EPHEMERIDA. The may-flies, also known locally as shad-flies, salmon-flies, June bugs and Canadian soldiers. The adults are sluggish insects with slender filaments at the caudal end of the body and large triangular front wings. The hind legs are much smaller, in some species rudimentary. The immature insect is aquatic and in most species feeds on decaying vegetable matter. It may live for several years, while the adult stage lasts only a few days.

May-flies of one species emerge as adults in large numbers within a short period and are sometimes very abundant near favorable bodies of water. They fly at twilight and can sometimes be seen in large gray clouds at a distance of more than a mile over the islands of Lake Erie, where they are especially abundant. In the cities bordering the lake they are attracted to lights and their dead bodies are sometimes swept up in bushels after a heavy flight. Under such conditions they are a nuisance but not a serious pest. Their value as food for nshes more than offsets what little harm they do. (A.W.L.)

EPHEMERIS. Almanac.

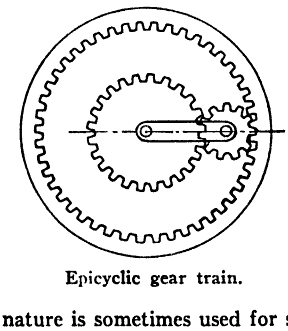
EPHIPPIUM. The thickened covering of the **carapace** of certain **crustaceans** which is thrown off as a case for the winter eggs. (A.W.L.)

EPHYRA. A saucer-shaped jellyfish **larva** with deeply notched margin which is produced by the segmentation of the primary **scyphistoma** larva and develops directly into the adult **jellyfish.** (A.W.L.)

EPICARDIUM. The thin covering of the vertebrate **heart,** continuous with the lining of the pericardial cavity. (A.W.L.)

EPICENTRUM. Earthquakes.

EPICYCLIC TRAIN. Combinations of **gears** having a motion resulting from rotation about an axis which, in itself, is in rotation, are known as epicyclic trains. A simple epicyclic gear train, consisting of three gears and an arm, is shown in the figure. Mecha-

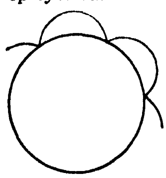


Epicyclic gear train.

nism of this nature is sometimes used for speed reducers The ratios of speed of the driven and driving elements are found by the following simple rule: consider, first, the gears locked and the arm turned, then the arm locked and the gears turned. The algebraic sum of the separate motions thus determined will give the speed ratio. (F.T.M.)

EPICYCLOID. An epicycloid is a certain type form of mathematical curve, which may be defined as follows:

If a circle of radius b rolls upon the exterior of a circle of radius a, a point on the first circle traces an epicycloid. Its **parametric equations** are:



Epicycloid.

$$x = (a + b) \cos \theta - b \cos \left(\frac{a + b}{b} \theta\right),$$

$$y = (a + b) \sin \theta - b \sin \left(\frac{a + b}{b} \theta\right).$$

This curve has been followed to some extent in the design of cycloidal gear teeth. (L.L.S.)

EPIDEMIC ENCEPHALITIS. This term was first applied to the von Economo type of encephalitis, or "encephalitis lethargica" which occurred in a world-wide epidemic beginning in 1917 and was most prevalent in North America between 1919 and 1926. Curiously, it has never reappeared. The disease was a serious one with a mortality rate of 40–100%. The etiological agent was never isolated though a **virus** was suspected. The clinical picture was characterized by extreme lethargy, coma, and weakness and paralyses, particularly of the cranial nerves.

In recent years, the **arthropod**-borne encephalitides have formed a group of growing frequency and importance. At present, infections produced by the following viruses are classified in this group: Western and Eastern equine encephalitis, Japanese B, St. Louis, Russian spring-summer, and louping ill of sheep. The virus in these encephalitides is transmitted by the bite of an insect—a species of mosquito or tick, depending on which disease is involved. In Western and Central United States, western equine (which causes encephalitis in horses as well as man), and St. Louis viruses are present in birds and domestic fowl; although these animals remain well, mosquitoes may acquire the virus by feeding on them, and in turn transmit the disease to man. These two types of encephalitis are of greatest importance in the United States. Eastern equine is rare, and Japanese B and Russian spring-summer do not occur in North America so far as is known.

The clinical picture in the arthropod-borne encephalitides is similar but varying in severity. Fever, headache, stiff neck, paralyses and stupor may occur. Fatality rates for St. Louis and Western equine infections vary between 5 and 22%. Treatment is non-specific, and residual paralyses and mental deterioration are common. A **vaccine** made from infected chick embryos conveys temporary immunity to eastern and western equine varieties. (D.M.H.)

EPIDEMIOLOGY. That branch of medical science which is concerned with the study of disease as it appears in its natural surroundings, and as it affects a community of people rather than a single individual. Epidemiology is largely concerned with infectious diseases; it has a statistical as well as an experimental side. The statistical includes the gathering of facts about the incidence, mortality rate, relation of climate, age, sex, race and many other factors to the appearance of a given disease. From these data, valuable information which is important in controlling epidemics of disease is obtained. In experimental epidemiology, the investigator may produce epidemics in laboratory animals for the study of certain problems, or he may go out in the field and study epidemics in man by laboratory means. Such work is important in elucidating the cause, the modes of transmission, and the insect vectors possibly concerned, as well as other facts of fundamental importance in public health. (D.M.H.)

EPIDERMIS. In insects, the outer layer of the non-cellular cuticula; here the cellular layer is called the hypodermis. In other invertebrates the cellular layer covering the body is called the epidermis. In vertebrates, the epidermis is the outer cellular layer of skin. The human epidermis consists of four layers, from without inward as follows: (1) a layer of horny flattened cells, (2) a layer of transparent cells, (3) layers of granular cells, (4) a layer of rounded pigmented cells. (R.S.M., A.W.L.)

EPIDERMOPHYTOSIS (Athlete's Foot). A contagious **fungus** infection most commonly seen on the foot, especially between the toes. Mild cases show only cracked skin between the toes, but in the severe forms the skin may be macerated, fissured, blistered and infected secondarily with bacteria. The disease may spread to the dorsum and sole of the foot, the fingers, and other parts of the body. Itching is usually marked. Allergic eruptions to the fungus, especially on the hands, may occur; these are called epidermophytids.

The fungus flourishes in damp places such as showers, swimming pools and Turkish baths, and the infection is thought to be spread by contact with contaminated objects in these places.

Thorough drying between the toes is the best preventive. Local applications such as sulfur-salicylic acid ointments and dilute iodine are effective in curing the chronic disease, but gentler treatment must be employed in the acute phase. (D.M.H.)

EPIDIABASE. Epidiorite.

EPIDIORITE. A term applied to gabbros, **dolerites**, and **diabases**, the **augite** of which has been partly altered to **hornblende**, thus approaching a **diorite** in mineral composition. The term is derived from the Greek meaning upon, plus diorite. (E.S.C.S.)

EPIDOTE. The mineral epidote is a basic orthosilicate of **calcium, aluminum** and **iron** whose formula may be written $HCa_2(Al,Fe)_3Si_3O_{13}$. The ratio of aluminum to iron ranges from 6:1 to 3:2. Epidote is found in prismatic **monoclinic** crystals, which may be acicular to fibrous. Fine granular and compact masses are common. The mineral displays one good cleavage, an uneven fracture; is brittle; hardness, 6–7; specific gravity, 3.25–3.5; luster, vitreous to resinous; typical color. pistachio green, but may be yellowish- to brownish-green, sometimes red, yellow, gray, white or colorless. Colorless to grayish streak; transparent to opaque. The characteristic color of ordinary epidote makes it usually an easily identified mineral. It occurs commonly in metamorphic rocks as gneisses and schists; however, it seems probable that under certain conditions it may appear as a primary mineral, for example in granitic rocks. The Urals, Austria, Switzerland, Italy, France and Norway are known for their occurrences of fine epidote crystals. In the United States epidote has been found in excellent specimens at Franconia and Warren, New Hampshire; Huntington, Massachusetts; Willimantic and Haddam, Connecticut; Chaffee County, Colorado, and Riverside County, California. The word epidote is derived from the Greek. The name pistacite, from the Greek word meaning the pistachio nut, has been occasionally applied to this mineral. It has been used as a gem stone but is in little demand for this purpose. (E S.C.S.)

EPIGENETIC. A term used by **petrologists** to denote physical and chemical changes, particularly in **igneous** and **sedimentary rocks,** which are clearly secondary to (later in time) the conditions under which the rock originated. This term is commonly used by the students of **ore** deposits to designate minerals formed after the enclosing wall rocks, in contrast to those minerals formed contemporaneously with the wall rocks. The latter minerals are said to be syngenetic. In the case of the sedimentary rocks the term is used to describe textures, structures and mineral aggregates,

of non-metamorphic origin, which have originated during the post-lithification history of the formation. Thus **flint, chert, concretions,** etc., may be described as being either epigenetic or syngenetic. (R.M.F.)

EPIGLOTTIS. A flap developed from the floor of the **pharynx** of terrestrial vertebrates which covers the opening to the **respiratory system** (glottis) while the animal swallows. (A.W.L.)

EPIGYNUM. A plate above the opening of the reproductive duct of the female **spider.** (A.W.L.)

EPIGYNY. Fruit.

EPILEPSY. A symptom complex characterized by recurrent convulsive seizures. In approximately 75% of cases, no cause can be assigned to the attacks (idiopathic or genetic epilepsy) while in 25%, described as acquired epilepsy, the causes are brain injury, congenital defect or birth injury to the brain, brain tumor, infections of the brain, or interference with cerebral blood supply due to vascular disease. The **pathology** is thus varied, except in the idiopathic type, where no organic changes can be demonstrated at autopsy.

Epilepsy occurs in roughly 0.5% of the population of the United States—or in about 600,000 individuals. Although epilepsy per se is not inherited, the predisposition to the disease is inherited. The pattern of the brain waves as shown on an **electroencephalogram,** a record of the electrical **potentials** of the brain, is an hereditary trait. Abnormal patterns, called cerebral dysrhythmia, are characteristic of an individual who is predisposed to epilepsy even though he may never develop seizures. If electroencephalograms are taken of the members of an epileptic's family, it will be found that a large proportion of them have cerebral dysrhythmia and are, therefore, potential epileptics.

Attacks of epilepsy usually begin in childhood or adolescence in the idiopathic type. Both sexes are equally affected. The seizures vary from transient loss of consciousness (petit mal) to violent convulsions (grand mal). Petit mal occurs without warning, and is characterized by sudden loss or impairment of consciousness which comes on abruptly, lasts a few minutes and ceases abruptly. Psychomotor seizures are similar, but longer attacks, marked by complete **amnesia** and loss of contact with the environment, without loss of activity. The individual may perform purposeful acts, but after the confusion clears, he has no recollection of what happened to him. Grand mal begins with a warning **aura** in about 50% of cases. The aura consists of various strange indescribable sensations, dizziness, and sometimes discomfort in the abdomen. It may be very brief and followed immediately by loss of consciousness, rigidity of the muscles, and cessation of breathing. If the patient is standing, he falls to the floor. His face becomes a livid blue and the veins engorge; perspiration and saliva flow. When breathing begins again, a period of violent intermittent muscle jerkings begins. At the same time frothy saliva is blown from the lips as deep respiratory movements begin. A severe convulsion is followed by heavy sleep, lasting several hours. On awakening, the individual often vomits, complains of headache and muscular soreness, and is depressed in spirits. Convulsions occur at varying intervals, sometimes only once a year, or as often as many times a day. If the seizures follow one another in rapid succession without the regaining of consciousness between attacks, the condition is described as status epilepticus. One-sided seizures, or those localized to one part of the body, are in general due to acquired epilepsy, or some recognizable brain lesion.

The treatment of acquired epilepsy is the removal, if possible, of the cause. In idiopathic epilepsy, it resolves itself into attempts to prevent the seizures by various anti-convulsant drugs. Of these phenytoin sodium (dilantin sodium), phenobarbital, and bromides are the most effective, and in the order named. During a convulsion care should be taken to protect the individual from injury. It is important to put some soft substance between the teeth to prevent biting of the tongue. It is useless to attempt to cut short a single attack, although status epilepticus may be shortened by phenobarbital hypodermically.

A certain proportion of epileptics, after years of seizures, deteriorate mentally. The number so affected is not as great as was formerly believed; probably not more than 10% of severe epileptics ever exhibit marked deterioration, and 25% mild changes. The unpleasant traits in the so-called epileptic personality—moodiness, egotism, quarrelsomeness, occur primarily in the group showing some deterioration; they are rare in the mentally normal.

The prevention of epilepsy is a problem in **eugenics.** Ideally, not only the epileptic, but all individuals with cerebral dysrhythmia should marry partners with normal brain waves in order to reduce the existing chance (about 1 in 40) of their children having epilepsy. (D.M.H.)

EPINASTY. Movement in Plants.

EPIPHARYNX. A fold on the inner surface of the upper lip (labrum) of the insect mouth. (A.W.L.)

EPIPHRAGM. A tough membrane of calcified mucus with which some **snails** close the aperture of the shell during periods of drought. (A.W.L.)

EPIPHYTES. A striking feature of tropical forests is the abundance of plants which grow attached to other plants. These attached plants are called epiphytes, which means plants growing on other plants They are found both on the main trunk and on the branches, often far above the ground. In many cases the epiphyte grows on the under side of a branch to which it is firmly fastened by its roots. Epiphytes gain nothing but support, and a more favorable position of growth because of better light conditions and other environmental factors; they do not obtain any **nutrients** from the supporting plants, as parasites would. Particularly noteworthy among epiphytes are many **ferns, aroids** and especially **orchids.** Frequently as in the orchids, the **roots** of the plants are so modified as to absorb water directly from the atmosphere.

In the strictest meaning of the word, many lower plants including **algae, fungi, lichens** and **mosses** are epiphytes, since they are often found growing on other plants, not only in tropical regions but in temperate regions as well. (R.M.W.)

EPIPODITE. Biramous appendage. The epipodites of some **crustaceans** are filamentous or branching gills. (A.W.L.)

EPIPODIUM. A lateral ridge on the molluscan foot. (A.W.L.)

EPISTASIS. The masking of one hereditary character by another which is genetically independent. (See **Heredity.**) (A.W.L.)

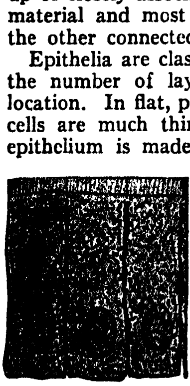
EPISTAXIS. Hemorrhage from the nose. Nosebleed. (R.S.M.)

EPISTOME. A projection above the mouth of some **bryozoans.** (A.W.L.)

EPITHELIUM. Tissue which covers surfaces and lines hollow organs, and the derivatives of these tissues,

whether solid or hollow. All epithelial tissues are made up of closely associated cells with very little intercellular material and most of them have one surface free and the other connected with an underlying tissue.

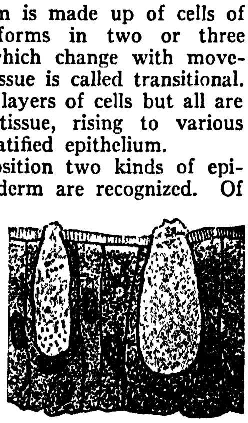
Epithelia are classified according to the form of **cells**, the number of layers, and the embryonic origin and location. In flat, pavement, or squamous epithelium the cells are much thinner than their diameter. Cuboidal epithelium is made up of cells approximately as thick as their width. They are not strictly cuboidal but are polyhedral prisms. Columnar epithelium contains cells that are much higher than their diameter. Glandular epithelia are usually of the two latter forms. Any of these forms of cells may occur in more than one layer as a stratified epithelium, but flat epithelia are more often stratified and thicker cells usually form a single layer, or a simple epithelium. In some cases the epithelium is made up of cells of several forms in two or three layers, which change with movements of the part. Such a tissue is called transitional. Others appear to have several layers of cells but all are attached to the underlying tissue, rising to various heights. This is a pseudo-stratified epithelium.



Simple columnar epithelium from intestinal lining. (*Kimber and Gray, Textbook of Anatomy and Physiology, Macmillan Co.*)

According to origin and position two kinds of epithelia derived from the mesoderm are recognized. Of these, endothelium lines the circulatory organs and mesothelium lines the body cavity. Other special types of epithelium are derived from each of the three germ layers. The free surfaces of some bear cilia.

The cells of many epithelia produce special secretions and in some cases these glandular layers are highly developed to form massive structures known as **glands**.



Goblet cells from epithelium lining large intestine. (*Kimber and Gray, Textbook of Anatomy and Physiology, Macmillan Co.*)

Most epithelia rest on a thin basement membrane or membrana propria derived from the connective tissues. (A.W.L.)

EPITOKE. The posterior sexual portion of the body in certain **annelids**. In one of the Pacific species this part of the worm breaks off when mature and rises to the surface. In this stage it is the palolo worm of the Pacific Islands. The anterior asexual portion (atoke) remains in the burrow and produces another epitoke. (A.W.L.)

EPOCH. A subdivision of the geologic time scale which is divided as follows: Era, Period, Epoch and Age. (R.M.F.)

EPSOM SALTS. **Magnesium Sulfate.**

EQUAL ARM BALANCE. **Balance.**

EQUALITIES. An equality is a statement that two mathematical expressions are equal. Equalities are of two kinds: identical equalities or **identities**, and conditional equalities or **equations**. (L.L.S.)

EQUALIZER. It is very difficult to construct apparatus and particularly **lines** for communication circuits which will pass all the necessary frequencies equally. Often it is necessary to insert networks whose function is merely to restore the original relation of the various frequencies. These are called equalizers or, sometimes, inverse networks. Usually they are loss circuits which will cause more loss in those frequencies which had been attenuated less and the opposite for those attenuated the most. Thus the equalizer shows a frequency response which is the inverse of the system it is intended to equalize so the result of connecting it in the circuit is to restore the over-all response to a flat characteristic. The term equalizer is also used for the series of connections sometimes made in d-c machines to insure equal current distribution in the conductors. (L.R.Q.)

EQUATION OF A LOCUS. The equation of a given locus is the **equation** which is satisfied by the **coordinates** of all points of this locus, and of only such points. (L.L.S.)

EQUATION OF STATE FOR AIR. For any gas the equation of state per mol is:

$$PV = RT;$$

where V = volume;
P = pressure;
R = universal gas constant;
T = abs. temperature.

For one gram this becomes

$$PV = \frac{RT}{m},$$

where m is the molecular weight of the gas. For G grams this becomes,

$$PV = \frac{GRT}{m}.$$

This equation is valid for each of the constituent gases of the atmosphere.

For nitrogen,
$$P_nV = \frac{G_nRT}{m_n}.$$
For oxygen,
$$P_oV = \frac{G_oRT}{m_o}.$$
For argon,
$$P_aV = \frac{G_aRT}{m_a}.$$
For water vapor,
$$P_wV = \frac{G_wRT}{m_w}.$$

When there is no water vapor present in the atmosphere, these equations can be combined as follows:

$$P_tV = (P_n + P_o + P_a)V$$
$$= RT\left[\frac{G_n}{m_n} + \frac{G_o}{m_o} + \frac{G_a}{m_a}\right] = RT\left(\frac{G_t}{m_t}\right).$$

In these equations P_t is the total pressure of the nitrogen, oxygen, and argon. Also G_t is the total mass of the gases, and m_t is the molecular weight of the mixture. m_t has a numerical value of 28.97.

Because water vapor is always present in varying quantities in the atmosphere, corrections in the equation of state must be made in accordance with the amount of water vapor present. Procedure is as follows:

$$PV = (P_t + P_w)V$$
$$= RT\left[\frac{G_t}{m_t} + \frac{G_w}{m_w}\right] = RT\left[\frac{G}{m_t} - \frac{G_w}{m_t} + \frac{G_w}{m_w}\right].$$

In these equations P is the total pressure of the air gases plus the water vapor, and G is the total mass of the air gases plus the water vapor.

This equation can be rearranged and simplified:

$$PV = RT\frac{G}{m_t}\left[1 - \frac{G_w}{G}\left(1 - \frac{m_t}{m_w}\right)\right].$$

m_t has a value of 28.97 and m_w has a value of 18.00. This equation is easily reduced to

$$PV = RT\frac{G}{m_t}\left[1 + 0.6\frac{G_w}{G}\right].$$

Virtual temperature of the air is defined as,

$$T' = T\left[1 + 0.6\frac{G_w}{G}\right].$$

Virtual temperature is in effect the temperature of a mass of dry air having the same density of another mass of air containing water vapor. Virtual temperature is always greater than real temperature except when G_w is nil.

The equation of state for real air becomes

$$PV = \frac{RT'G}{m_t}.$$

If R, the universal gas constant, is made into a specific gas constant for air by letting $\frac{R}{m_t} = R_a$, then for one gram of air the equation of state becomes $PV = R_aT'$. (P.E.K.)

EQUATION OF TIME. Time.

EQUATIONS. An equation is an **equality** in which both members are equal for certain particular values of the symbols involved but not for all values. To emphasize this, an equation is sometimes called a conditional equality or a conditional equation.

An equation is indicated by putting the equality sign = between the two sides or members of the equation.

An equation with one unknown is an equality which holds for certain particular values of the unknown but not for all values of the unknown.

Equations are classified into many types. There are equations with one or more unknown **numbers** and equations with one or more unknown **functions.** Equations with one or more number unknowns are classified into **algebraic equations** and **transcendental equations;** each of these two classes is further subdivided into other sub-classes. Equations with functional unknowns are classified into **differential equations, integral equations, difference equations,** functional equations, etc.; each of these classes is also divided into subclasses. (L.L.S.)

EQUATIONS, CHEMICAL. Chemical Changes.

EQUATIONS OF MOTION. Kinematics.

EQUATOR. A plane perpendicular to the axis of rotation of the **earth** and passing through the center of the earth will intersect both the surface of the earth and also the **celestial sphere** in great circles. These great circles are known as the terrestrial and celestial equators. Some navigators refer to the celestial equator as the equinoctial. (W.K.G.)

EQUATORIAL AIR. Air Masses.

EQUATORIAL COORDINATES. Equatorial coordinates are a system of **spherical coordinates** in which the origin may be the eye of the observer (in which we have the apparent system of coordinates), the center of the earth (geocentric system), or the center of the sun (heliocentric system). The fundamental line in this system is the line joining the poles of rotation of the earth which cuts the **celestial sphere** in its poles of rotation. The plane perpendicular to the fundamental line through the origin is the celestial **equator.** The fundamental direction in the plane may be either the point of intersection of the **local meridian** with the celestial equator, which is above the horizon, or the **Vernal equinox.**

To locate an object in this system of coordinates, a plane is passed through the object and the line joining the poles of rotation and this plane will cut out a great circle, known as an **hour circle,** on the celestial sphere perpendicular to the plane of the equator. The **declination** of an object is the angular distance of the object north (+) or south (−) of the celestial equator measured in the plane of the hour circle through the object. The **hour angle** of the object is the angular distance measured in the plane of the equator from the point of intersection of the meridian above the horizon to the point of intersection of the hour circle through the object in the direction of apparent rotation (west) of the celestial sphere. The right ascension of the object is the angular distance, measured in the plane of the equator from the vernal equinox to the point of intersection of the hour circle in a direction (east) contrary to the direction of apparent rotation of the celestial sphere. For purpose of convenience both right ascension and hour angle are frequently expressed in units of hour, minutes and seconds of time, rather than the more common angular notation of degrees, minutes, and seconds of arc.

Due to the fact that the local meridian remains fixed as the celestial sphere apparently rotates, the hour angle of an object is continually changing. Since both the vernal equinox and the hour circle rotate with the celestial sphere both the right ascension and declination of the object remain fixed as the sphere rotates. However, both right ascension and declination change slowly due to **precession** and **nutation.** In tabulating these coordinates in **star catalogues** the values are given for the position of the equinox for some particular date and the corrections necessary to reduce the positions to the present date must be applied. (W.K.G.)

EQUATORIAL FRONT. Fronts.

EQUATORIAL TELESCOPE. A **telescope** so mounted that it may be moved parallel to the **equatorial coordinates** of **hour angle** and **declination** is known as an equatorial telescope, or simply as an equatorial. In this form of mounting one axis, known as the polar axis, is parallel to the axis of rotation of the earth, and the other axis, about which the telescope may be rotated, is perpendicular to the polar axis and known as the declination axis. From this arrangement of the axes, as the telescope itself is rotated about the declination axis it must move in a plane perpendicular to the **equator,** hence parallel to hour circle or in the direction of declination. The rotation of the declination axis about the polar axis, with the telescope remaining fixed in declination, will cause the telescope to move parallel to the equator, hence in the coordinate of hour angle.

The majority of equatorials are carried on a single pier. This form of mounting has the difficulty that the telescope will frequently run into the pier when the hour angle is close to zero. To avoid this several other methods of supporting the polar axis have been devised. Perhaps the most common is the so-called English mounting, in which the two ends of the polar axis are supported on separate piers, with the telescope free to pass through zero hour angle.

The most difficult adjustment of the equatorial is to get the polar axis strictly parallel to the axis of rotation of the earth. When this has been accomplished the instrument is by far the most convenient of all forms of mounting. If the instrument is rotated about the polar axis from east to west at exactly the same rate that the earth is rotating about its axis from west to east, the telescope lens will remain fixed relative to objects on the celestial sphere. Hence once the instrument is set on

a star, clock work may be devised to keep the telescope "following."

Many ingenious modifications of the equatorial mounting, such as the **Coudé**, have been devised. Most such modifications have the comfort of the observer in mind and sacrifice both light and good definition to attain this end. (W.K.G.)

EQUIANGULAR SPIRAL. **Logarithmic Spiral.**

EQUIDAE. **Pleistocene.**

EQUILATERAL HYPERBOLA. **Hyperbola.**

EQUILIBRIUM, BIOLOGICAL. The state of coordination which maintains an animal in normal posture.

Equilibrium of aquatic animals such as the fishes is maintained by the resistance of the surrounding water in relation to specialized body form, by muscular movements of body and fins, and by the gas-filled swim bladder. The bodies of most fishes are heavier above, as is shown by their floating back downward when dead, but the combination of these factors maintains their erect position.

Terrestrial animals maintain their posture by constant muscular adjustment in response to stimuli received by sensory organs in the soles of the feet and in the muscles and tendons. A portion of the inner ear of vertebrates is also a center of equilibrium. End organs in the semicircular canals of this organ are stimulated by movement in the liquid filling the canals when the animal moves. The three canals lie in the three planes of space so that at least one is activated by any movement. The results of their reaction are transmitted to one of the lower brain centers, whence the proper impulses are relayed to the muscles.

Equilibrium in flight demands very delicate coordination of essentially the same type. In insects and bats it is supposed to be accomplished partly through delicate sense organs located in the wings. (A.W.L.)

EQUILIBRIUM, CHEMICAL. The fundamental law of chemical equilibrium is that enunciated by Le Chatelier (1884), and may be stated as follows:—If any stress or force is brought to bear upon a system in equilibrium, the equilibrium is displaced in a direction which tends to diminish the intensity of the stress or force. This is equivalent to the "principle of least action." Its great value to the chemist is in that it enables him to predict the effect upon systems in equilibrium of changes in temperature, pressure, and concentration.

The chemical system, **hydrogen-nitrogen-ammonia,** furnishes a notable example of the application of the principle.

$$\underbrace{\underset{1\text{ vol.}}{\text{Nitrogen}} + \underset{3\text{ vol.}}{\text{Hydrogen}}}_{4\text{ vol.}} \rightleftarrows \underset{2\text{ vol.}}{\text{Ammonia}} + \underset{\substack{12{,}000\text{ calories}\\ \text{per mol ammonia}}}{\text{Heat}}$$

At the temperature 700° C. and pressure 1 atmosphere, the equilibrium percentage of ammonia is 0.03 in the above system, and at 100 atmospheres 2.5. Increase of pressure shifts the equilibrium towards the side of the smaller total volume, at a constant temperature. Decrease of pressure shifts the equilibrium towards the side of the larger total volume, at a constant temperature. Systems of the same initial and final volumes are unaffected, as to equilibrium amounts of materials, by change of pressure.

At the pressure 100 atmospheres, and temperature 700° C., the equilibrium percentage of ammonia is 2.5 in the above system, at 600° C. it is 5, at 500° C. it is 10. Increase of temperature shifts the equilibrium in the direction which absorbs heat, at a constant pressure. Decrease of temperature shifts the equilibrium in the direction which evolves heat (van't Hoff's principle, 1884).

At constant pressure and temperature, the equilibrium is shifted away from the side subjected to an increase in concentration of any constituent, or towards the side subjected to a decrease in concentration of any constituent. (See **Chemical Changes.**) For the qualitative effect of temperature change, one may visualize the heat of an equilibrium reaction as material, and an increase of temperature (heat intensity) as operating to increase the concentration of "heat material" thus shifting the equilibrium away from the side of its increased concentration, and conversely. It is possible, knowing the heat of reaction, Q, on the assumption that the heat of reaction is constant between two given (absolute) temperatures, T_1 and T_2, to calculate the equilibrium constant K_2 (at T_2) when the equilibrium constant K_1 (at T_1) and the gas constant, R (equals 2 calories per mol), are known, by the application of van't Hoff's equation:

$$\log_{10} K_2 - \log_{10} K_1 = \frac{Q}{2.3 \times R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right).$$

In this way the quantitative effect of temperature change on the state of equilibrium may be calculated.

In reactions of the ammonia synthesis type, to which **sulfur trioxide** from **sulfur dioxide** plus **oxygen** also belongs, the rate of reaction decreases with lowering of the temperature as the conversion is increased. There is, in such types of reactions, a limit to the practicable lowering of the temperature. The finding of a positive **catalyzer** for a given reaction of this sort permits the operation to gain the advantage of equilibrium conversion at the lower temperature as well as the increased rate of reaction at that temperature due to the presence of the catalyzer. (See **Chemical Changes.**) The time yield of product is, therefore, very important, and, with a catalyzer, the space-time yield.

Systems in equilibrium are divided into two great divisions, according to whether they are (A) homogeneous, that is, chemically and physically uniform throughout, or (B) heterogeneous, that is, not uniform throughout but consisting of two or more phases. Each phase is a homogeneous, physically distinct, and mechanically separable portion of a system. For example, ice, water, water vapor are three different phases (solid, liquid, gas) of the substance water. There can be only one gas phase of a system, and only one liquid phase where a *single* homogeneous solution is present. But the number of liquid and of solid phases in general is limited by the number of components (not constituents) of a system. The number of components is the least number of constituents, *independently* variable, and requisite to compose each and every phase. For example, the system consisting of saturated solution in water (H_2O) of **sodium** sulfate (Na_2SO_4) plus solid sodium sulfate decahydrate ($Na_2SO_4 \cdot 10H_2O$) plus water vapor consists of three phases (a) gas, (b) solution, (c) solid sodium decahydrate. The *least* number of constituents, independently variable in amount *and* requisite to compose each and every phase is two, namely, Na_2SO_4 and H_2O. These, therefore, are the two components of this system. Since zero and negative as well as positive amounts of compounds are permitted in expressing the composition of each phase of any system, the three phases of this system are composed of the following components:

(*a*) Gas phase, zero Na_2SO_4 plus H_2O
(*b*) Liquid phase, Na_2SO_4 plus H_2O
(*c*) Solid phase, Na_2SO_4 plus H_2O

The number of components in the ice-water-water vapor system is one, namely, H_2O.

To systems in which equilibrium depends solely upon the following variables, namely, (1) composition of each and every phase, (2) temperature, and (3) pressure, the **phase rule** (Willard Gibbs, 1874) applies: The number

of variables, that is (1) the number of components, C, plus (2) temperature plus (3) pressure, above, equals the number of phases, P, plus the number of degrees of freedom, F. The number of degrees of freedom of a system is the least number of the above variables which must be arbitrarily fixed in order to define the condition of the system.

$$C + 2 = P + F.$$

The phase rule applies to true equilibrium systems, where the equilibrium can be reached from either side, and, furthermore, takes no account of the time involved to attain equilibrium. The phase rule is a qualitative statement, whereas the law of mass action (concentration effect) is quantitatively applicable to those equilibrium systems where the reaction which occurs may be considered to take place in a homogeneous system, e.g., gas phase, or solution phase. (See **Chemical Changes.**)

In a one-component system, $P + F = 3$, and physical changes only occur. When only one phase is present, for example, liquid water (no vapor, no solid) the system is bivariant, that is, two variables—temperature and pressure—may be independently changed over a range. When a second phase, either vapor or solid appears through a sufficient change of temperature or pressure or both, or when two phases are originally present, the system is univariant, that is, one variable—either temperature or pressure—may be independently changed over a range. When the third phase appears or when three phases are originally present, the system is invariant, that is, a change of either temperature or pressure destroys the equilibrium, and the disappearance of one of the phases occurs. A system of one component in three phases is invariant and the conditions are represented by a point known as the triple point. The triple point for water is 0.007° C., 4.6 mm. mercury pressure. When the total pressure is one atmosphere (760 mm.) the equilibrium temperature of water-ice is 0.000° C., and when the water vapor pressure is one atmosphere the equilibrium temperature of water-water vapor is 100.000° C.

If, in dealing with any system, the gas phase or pressure may be neglected, on account of constancy or slightness of effect, the phase rule is simplified for practical purposes to $C + 1 = P + F$, and, if both may be neglected, to $C = P + F$.

Many two- and three-component systems have been studied and recorded in detail. The **iron-carbon** system is one that has attracted much attention and been of great value in iron metallurgy. (R.K.S.)

EQUILIBRIUM MOISTURE CONTENT. Drying.

EQUILIBRIUM OF FORCES. A state of balance between or among forces. The much used term equilibrium is here confined to its dynamical sense; such subjects as thermal equilibrium, radioactive equilibrium, etc., are treated in appropriate places elsewhere. Unless otherwise specified, the term refers to that set of conditions to which a system of forces must be adjusted in order that a free body acted upon by them will experience no acceleration. This is somewhat illogically termed "static equilibrium," to distinguish it from the "kinetic equilibrium" with which **D'Alembert's principle** is concerned.

Two conditions are necessary for the equilibrium of a set of forces. 1. The vector sum of the forces must be zero (see **Vector Addition**); then if they are resolved into rectangular components, the algebraic sums of the X, the Y, and the Z components must separately reduce to zero. 2. The algebraic sum of the torques of the forces about each of any three mutually perpendicular axes must be zero; the body then has no tendency to rotate about any axis. (See **Statics** and **Graphical Statics.**)

A body or a set of bodies under the action of forces may be in stable, unstable, or neutral equilibrium. For any one of these, a very slight displacement or change of relative position may be regarded as taking place without change of energy, a fact known as the "principle of virtual work." If the energy is really constant, the equilibrium is neutral; if it is at a minimum, the equilibrium is stable (see **Least Energy Principle**); if it is at a maximum, the equilibrium is unstable. The degree of stability in the second case may be expressed as the amount of energy which must be supplied to render the system unstable. These various ideas may be illustrated by a body suspended by a string, a sphere resting on a horizontal plane, a pencil balanced on its point; and by blocks, pyramids, etc., on a table. (L.D.W.)

EQUINOCTIAL. Equator.

EQUINOX. The line of intersection of the plane of the earth's **equator** with the plane of the **ecliptic** (the **line of nodes** of the earth) intersects the **celestial sphere** in two diametrically opposite points known as the equinoxes. As seen from the earth the sun apparently passes through each of the equinoxes once each year, passing through the vernal equinox on approximately March 21st and the autumnal equinox on approximately September 21st.

The great circle passing about the **celestial sphere** through the equinoxes and the pole of the ecliptic is known as the equinoctial colure. (W.K.G.)

EQUIPARTITION OF ENERGY. If a great number of perfectly elastic, rapidly moving particles are turned into an enclosure together and are allowed time to mingle, darting about and striking or otherwise encountering each other, the kinetic energy which they possess becomes distributed in accordance with the famous principle of equipartition of energy, or Maxwell-Boltzmann law, as enunciated by Boltzmann. Each particle has a number of **degrees of freedom,** determined by its character. (For the molecules of a diatomic gas, such as nitrogen, the effective number is 5; plus some others not ordinarily concerned with thermal energy.) The equipartition principle states that the average energy taken up by motions in each of the several degrees of freedom is the same, and is independent of the sizes and masses of the particles. (For a gas it is equal to ½ the product of the Boltzmann constant by the absolute temperature of the gas.) Thus when heat energy is imparted to a pure diatomic gas, ⅕ of it goes into each degree of molecular freedom which heat can affect. Three of these degrees of freedom are concerned with motions of translation, so that ⅗ of the energy takes this form. And indeed, when we calculate the change in translational energy due to rising the temperature of one gram of the gas one degree (see **Kinetic Theory**), it is found to be almost exactly ⅗ of the specific heat as measured at constant volume, which represents the total imparted energy. One of the strongest supports of the principle comes from quantitative observations on the **Brownian movement.** Many other examples occur in physics. (L.D.W.)

EQUIVALENT CIRCUIT. This term is applied to an electrical circuit which is electrically equivalent to another circuit, or sometimes, to a mechanical device. Equivalent circuits of mechanical systems or electromechanical systems such as loud-**speakers** enable the designer to apply methods of circuit analysis and often obtain a solution easily which would be very difficult if not impossible otherwise. The equivalent circuit method is used extensively in the analysis of communications circuits, particularly those involving vacuum **tubes.** The tube itself may be replaced, for instance, by a generator having a generated voltage equal the amplification factor of the tube times the applied grid voltage and an internal resistance equal the dynamic **plate resistance** of the tube. While this does not give the d-c solution of the tube circuit it does allow the circuit to be simplified

for alternating currents and these are usually the ones of interest. Similarly, many other types of electrical circuits may be simplified in terms of equivalent circuits, sometimes giving all the necessary solutions, sometimes giving solutions for limited conditions, but, in most cases, greatly decreasing the labor involved in analyzing the circuit or equipment. (L.R.Q.)

EQUIVALENT EQUATIONS. Two equations in one unknown are said to be equivalent when they have the same **roots.**

An equation is changed to an equivalent equation by the following transformations:

1. When the same number or expression is added to or subtracted from each side of the equation.
2. When both sides of the equation are multiplied or divided by the same number or expression, provided that number is not 0 and the expression does not contain the unknown. (L.L.S.)

EQUIVALENT MONOPLANE. The monoplane wing which would duplicate some of the important aerodynamic characteristics of a multiplane (such as a sesquiplane, a biplane or a triplane) is termed an "equivalent monoplane." In studies of performance and stability it is much simpler to use the air stream reactions on an equivalent monoplane than to work with the interacting forces on two or more wings. The span of the monoplane of equivalent **induced drag** is kb, where b is the multiplane wing span and k is the "apparent span factor." In former years k was extensively investigated, but in recent aviation history the trend has been away from multiplanes on account of their inferior aerodynamic performance. The air forces acting on the equivalent monoplane were considered to be localized on an "equivalent mean aerodynamic chord" and theories were derived for estimating the location of this imaginary chord. (F.T.M.)

EQUIVALENT PARASITE AREA. **Flat-Plate Area.**

EQUIVALENTS, CHEMICAL. **Chemical Composition.**

EQUUS. **Fossil Mammals.**

ERA. One of the five major subdivisions of the **geologic time-scale.** The formations that belong in any one era are spoken of as a group. (R.M.F.)

ERBIUM. Symbol: Er. Atomic number: 68. Atomic weight: 167.2. Density: 4.77. (**Isotopes:** page 290.) Type of compound: Er_2O_3. Color of salts: red. Discovered by Mosander in 1842. A member of the **yttrium** sub-group of the rare earth metals. (R.K.S.)

EREPSIN. **Enzymes.**

ERG. The c.g.s. absolute unit of **work** and of **energy.** It is the centimeter-dyne; that is, the work done, or the energy transferred, when the continuous exertion of one dyne of force upon a body is accompanied by a displacement of one centimeter in the direction of the force The erg is so small that often the more convenient **M.K.S. unit,** called the joule, is used; 1 joule equals 10^7 ergs. One foot-pound is approximately 1.355 joules. (L.D.W.)

ERGOMETER. **Power.**

ERGOSTEROL. **Alcohols and Ethers; Vitamins.**

ERGOT. A **fungus** which grows upon and replaces the grain or rye. (See **Diseases of Plants.**) Ergot in the body contracts smaller arteries and smooth muscle fibers —especially that of the **uterus.**

Preparations of ergot are used medically to cause contraction of the uterus after childbirth to check hemorrhage. It is questionable whether it has any abortifacient properties in early pregnancy.

During recent years a form of ergot has been used for the treatment of migraine.

Continued use of ergot produces chronic spasm of the small arteries in the hands and feet, producing gangrene. In the past gangrene commonly occurred in certain European countries from eating bread made from ergot-infected rye. (See **Ascomycetes.**) (R.S.M., D.M.H.)

ERGOTIMINE. **Alkaloids.**

ERGOTOXINE. **Alkaloids.**

ERIOMETER. **Diffraction.**

ERITHRITE. The mineral erythrite is a rather rare mineral of secondary origin. Chemically it is a hydrous **cobalt arsenate** corresponding to the formula $Co_3As_2O_8 \cdot 8H_2O$, the cobalt being replaced at times by **nickel, iron** or **calcium.** It is found in **monoclinic** crystals, masses, and in crusts with other cobalt minerals. It is a soft mineral; hardness, 1.5–2.5; specific gravity, 2.95; luster, adamantine to vitreous although massive varieties may be dull to earthy; color, red, occasionally gray; transparent to nearly opaque. It is known from Bohemia, Saxony, Baden; Chalantes, France; Tunaberg, Sweden; Cornwall and Cumberland, England; Cobalt, Province of Ontario, Canada; and in the United States from Nevada and California. Erythrite takes its name from the Greek meaning red. (E.S.C.S.)

ERMINE. Mammalia, Carnivora. The white winter phase of various species of **weasels** and the stoat of the Old World. These animals turn white only in colder northern latitudes and always retain the black-tipped tail with which royal ermine is spotted. The fur is fine but its value is less than is popularly supposed. (A.W.L.)

EROS. Of all of the more than 1300 **asteroids** which have been discovered up to the present time, Eros has probably attracted the most attention. The interest in this object comes from the fact that when the object comes to **opposition** at the time of **perihelion** passage it is distant from the earth by only 13,840,000 miles, or is closer to the earth than any other member of the **solar system** whose orbit is accurately known, except the moon. At the time of such close approach the **parallax** of Eros is nearly 60" and is larger than that of any other member of the solar system. Hence, observations made of this object when at close approach provide accurate determinations of its parallax, and, with the **orbit** of the planet accurately determined, **solar parallax** may be more accurately determined than from any other known object. These favorable close oppositions of Eros come at rather widely separated intervals, those since discovery coming in 1901 and 1931. At both of these times many accurate observations, both visual and photographic, were made and from them a number of important astronomical constants have been determined.

Because of the close approach of Eros to the earth the orbit of Eros suffers large **perturbations** from the earth. A study of these perturbations provides data for the determination of the ratio of mass of the earth and the sun. With this mass ratio determined the solar parallax may be accurately determined.

Eros itself is a small object, between 15 and 20 miles in diameter. The light from it varies at times with a period of about 5 hours, and the regularity of the light variation can only be explained on the hypothesis that the object is in rotation with this period. At the time

of the close opposition of 1931 observations made in South Africa indicated that Eros is not spherical, but is "dumb-bell shaped."

Several other asteroids have been discovered which come closer to the earth than does Eros. These objects are very minute, and at present the observational material is too meager to permit of accurate determination of their orbits. (W.K.G.)

EROSION. The general term referring to the reduction of the land surface toward sea level by the various agencies of weathering, stream action, glacial action, wind action, etc. A similar term is denudation. The individual and combined processes of erosion are the primary surficial agencies in the sculpturing of topographic features and the development of scenery. Erosion also provides the material from which are formed the bulk of the fragmental, or **clastic, sedimentary rocks.** (R.M.F.)

ERRANTIA. A division of marine segmented **worms** including chiefly free-swimming species. Sometimes ranked as an order and sometimes as a division of the order Polychaeta. (A.W.L.)

ERRATIC. In geology, an ice-carried **boulder** or block, sometimes weighing many tons, which because of its lack of similarity to the bedrock or formation on which it rests, and the peculiarity of its position, must have been transported to its present resting place by a glacier or an iceberg. When erratics occur in sufficient quantity to form relatively pronounced topographic features these are called moraines. When erratics of similar or identical **lithology** show a well-defined lineal distribution from the parent outcrop they are called boulder trains. (R.M.F.)

ERROR. The term "error" is employed in many ways in **statistics.** It may refer to an error in calculation, but more often to an **error of observation,** or an **error of sampling.** Other uses of the term occur in the **standard error of estimate,** the **standard error of a statistic,** the types of error in the **Neyman-Pearson theory of testing hypotheses,** and the **experimental error** in the **analysis of variance.** Thus the term "error" generally is used in a technical sense and not in its ordinary meaning of a "mistake" or an "incorrect value." (L.A.A.)

ERROR OF ESTIMATE. The standard error of estimate is

$$\sigma_e = \sqrt{\frac{\Sigma(y - y')^2}{N}},$$

where y is the actual value of the **variable** and y^1 is the value predicted by an equation, N = number of items in the **sample.** The error of estimate in a particular instance is $y - y^1$. (L.A.A.)

ERROR OF OBSERVATION. Let y be an observed value of a **variate** and y^1 its correct value. Then we define an error of observation as $y - y^1$. Errors of observation are caused by experimental conditions. As long as all such errors are not in the same direction, no serious **bias** should arise. Usually we assume this to be the case. (L.A.A.)

ERROR OF SAMPLING. An error of sampling depends on the particular **sample** chosen. Each sample gives rise to various **statistics.** The difference between a statistic and the population value may be termed the sampling error. A sampling error is not a "mistake" in the common meaning of that term. It is an unavoidable consequence of the fact that samples vary. (L.A.A.)

ERRORS OF MEASUREMENT. Much of the routine work in any experimental research in the physical sciences is concerned with the eliminating, minimizing, or compensating for observational errors. By the error of any measurement is meant the result of the individual measurement minus the true value of the quantity measured. It may thus be either positive or negative. Errors may be broadly classified into two types: persistent or systematic errors, due to causes which endure throughout the whole series of observations and which, therefore, affect each individual observation alike; and accidental or chance errors, due to a combination of random influences which may be changed completely from observation to observation. These two classes may be illustrated, respectively, by measurements of a length with a ruler which is too long or too short, and by measurements of an angle with a surveyor's **transit** which is being shaken by the wind. Mistakes or blunders, due to the misreading of an instrument, etc., are not considered as errors of observation, but rather as errors of the observer.

Various standard devices for dealing with persistent or systematic errors will be found discussed under **physical measurements.** The treatment of accidental errors is discussed briefly in the article on **least squares.** (L.D.W.)

ERUPTION. A breaking-out of the skin, marked by various degrees of redness, swelling, and elevation. There are many types of eruption, some of which are characteristic of the disease which they accompany and are important in the diagnosis of these diseases. A drug eruption is one occurring after the use of a **drug** to which the individual is allergic. A plant eruption occurs after exposure of a sensitive subject to irritating substances found in certain plants, poison ivy for example. (D.M.H.)

ERUPTIVE. This term has the same general geological meaning as **effusive,** but is sometimes used in the much more general sense as synonymous with **igneous.** (R.M.F.)

ERYOPS. Fossil Amphibia.

ERYSIPELAS. An acute **inflammation** of the skin caused by infection with *streptococcus hemolyticus.* It is accompanied by high fever, **leucocytosis,** and sometimes **septicemia** and severe prostration. Infection usually takes place at the site of injury, sometimes a break in the skin too small to be visible. The face is the most common starting point of the infection. A small area of skin over the cheek becomes red and swollen. The margin of the lesion is raised and well demarcated; it spreads rapidly to cover the nose and involve the other cheek, giving the characteristic butterfly appearance. **Abscess** formation at the site of infection may occur as a complication. The most successful treatment is with sulfadiazine or other **sulfonamides** or **penicillin.** Relapses and recurrences in the same site are not uncommon. (D.M.H.)

ERYTHROCYTE. Blood.

ERYTHROXYLON. Coca.

ESCAPE VELOCITY. Rocket Flight.

ESCARPMENT. Used by physiographers and structural geologists to denote a line of steep slopes or cliffs. (See also **Cuesta** and **Scarp.**) (R.M.F.)

ESKER (OSE; plural, OSAR). Certain long, often winding, ridges formed of stratified sands and gravels

which occur within the glaciated regions of Europe and North America are called eskers. These pronounced topographic features are frequently several miles in length and because of their peculiar and uniform shape somewhat resemble railway embankments. Eskers represent the deposits of glacial streams which flowed within and under glaciers. After the retaining ice walls melted away the stream deposits remained as long winding ridges. (R.M.F.)

ESOPHAGEAL GLAND. Glands associated with pouches on the sides of the **esophagus** in earthworms. They secrete **calcium** carbonate. Also called calciferous glands. (A.W.L.)

ESOPHAGUS. The tube-like passage which connects the lower end of the **pharynx** with the stomach. It is about 10″ long, lies in front of the spine as it descends through the chest, and passes through the **diaphragm** just before it enters the stomach. Its walls are made up of circular and straight muscle fibers which allow for wave-like contractions to progress from above downwards. The inner surface contains many glands which secrete mucus for lubrication of its walls. The function of the esophagus is to mechanically pass food from the pharynx into the stomach. The main disorders affecting it are **tumors**, diverticula and stricture. Stricture usually results from the swallowing of corrosive substances. (R.S.M.)

ESSENCES. **Extracts.**

ESSENTIAL OILS. **Hydrocarbons; Volatile Oils.**

ESSEXITE. **Gabbro.**

ESTABLISHMENT OF A FORT. **Tides.**

ESTERIFICATION. Esterification is illustrated by the union of an alkoxy group such as C_2H_5O— and an acetyl group such as CH_3CO— in which case ethyl acetate ester $CH_3COOC_2H_5$ results. This is commonly accomplished by the use of an alcohol to supply the RO— group and an acid for the RCO— group, with the simultaneous formation of water HOH. The reaction takes time and is not instantaneous, and an equilibrium state is also established when sufficient time for this is allowed to elapse. The equilibrium investigated by Berthelot (1863) between acetic acid plus ethyl alcohol *and* ethyl acetate plus water is reported in the article on **Chemical Changes,** III. The End-point of Chemical Reactions. The rates of esterification and the equilibrium points for various acids and alcohols were studied by Menschutkin during the period 1879 to 1909, and the results are presented in the two following tables.

RATE OF ESTERIFICATION AND EQUILIBRIUM POINT FOR VARIOUS ALCOHOLS AND PHENOLS WITH ACETIC ACID IN EQUIVALENT AMOUNTS AT 155° C.

Alcohol: Name	Alcohol: Formula	% of Ester Obtained: In 1 Hour	% of Ester Obtained: At Equilibrium
Primary:			
Methyl	CH_3OH	56	70
Ethyl	$CH_3 \cdot CH_2OH$	47	67
n-Propyl	$CH_3 \cdot CH_2 \cdot CH_2OH$	47	67
n-Butyl	$CH_3 \cdot CH_2 \cdot CH_2 \cdot CH_2OH$	47	67
Allyl (propene-2-ol-1)	$CH_2{:}CH \cdot CH_2OH$	36	59
Benzyl	$C_6H_5 \cdot CH_2OH$	39	61
Secondary:			
sec-Butyl (dimethylcarbinol)	$(CH_3)_2CHOH$	27	61
Methylethylcarbinol	$(CH_3)(C_2H_5)CHOH$	23	59
Diethylcarbinol	$(C_2H_5)_2CHOH$	17	59
Diallylcarbinol	$(CH_2{:}CH)_2CHOH$	10	50
Menthol (2-methyl-5-isopropylcyclohexanol-1)		15	61
* *Tertiary:*			
Trimethylcarbinol	$(CH_3)_3COH$	1.4	6.6
Dimethylethylcarbinol	$(CH_3)_2(C_2H_5)COH$	0.8	2.5
Methyldiethylcarbinol	$(CH_3)(C_2H_5)_2COH$	1.0	3.8
Dimethyl-*n*-propylcarbinol	$(CH_3)_2(CH_3CH_2CH_2)COH$	2.2	0.8
Dimethyl-*iso*-propylcarbinol	$(CH_3)_2((CH_3)_2CH)COH$	0.9	0.9
Phenol	C_6H_5OH	1.5	8.6
Thymol (5-methyl-2-isopropylphenol)	$C_6H_3(CH_3)(5)((CH_3)_2CH)(2)OH(1)$	0.6	9.5

* Tertiary alcohols, upon heating, lose water, leaving unsaturated hydrocarbons, and give low yields of esters.

RATE OF ESTERIFICATION AND EQUILIBRIUM POINT FOR VARIOUS ACIDS WITH ISOBUTYL ALCOHOL IN EQUIVALENT AMOUNTS AT 155° C.

Acid		% of Ester Obtained	
Name	Formula	In 1 Hour	At Equilibrium
Formic	$H\cdot COOH$	62	64
Acetic	$CH_3\cdot COOH$	44	67
Propionic (methylacetic)	$CH_3\cdot CH_2\cdot COOH$	41	69
n-Butyric (ethylacetic)	$CH_3\cdot CH_2\cdot CH_2\cdot COOH$	33	70
Phenylacetic	$C_6H_5\cdot CH_2\cdot COOH$	49	74
Phenylpropionic (benzylacetic)	$C_6H_5\cdot CH_2\cdot CH_2\cdot COOH$	40	72
* *iso*-Butyric (dimethylacetic)	$(CH_3)_2CH\cdot COOH$	29	70
* Methylethylacetic	$(CH_3)(C_2H_5)CH\cdot COOH$	22	74
* Trimethylacetic	$(CH_3)_3C\cdot COOH$	8	73
* Methyldiethylacetic	$(CH_3)(C_2H_5)_2C\cdot COOH$	3	74
* Benzoic	$C_6H_5\cdot COOH$	9	73
* *p*-Toluic	$C_6H_4(CH_3)(4)COOH(1)$	7	77
Cinnamic	$C_6H_5\cdot CH{:}CH\cdot COOH$	12	75

* The rate of esterification is relatively slow for branched chain aliphatic and for benzenoid acids.
The equilibrium point is about 70 per cent (64 to 77 for the above acids) with isobutyl alcohol under the specified conditions.

Norris showed that the esterification reaction proceeds as stated above by use of the two following reactions:

$$CH_3\cdot CO\cdot SH + H\cdot OC_2H_5 \rightleftharpoons CH_3\cdot COOC_2H_5 + HSH$$

$$CH_3\cdot CO\cdot OH + H\cdot SC_2H_5 \rightleftharpoons CH_3\cdot COSC_2H_5 + HOH$$

and this has been confirmed using acid and alcohol containing the heavy isotope (18) of oxygen.

The esterification reaction can be speeded up by the use of a catalyst. Such a catalyst is hydrogen ion say from hydrochloric or sulfuric acid. Side reactions may occur, hydrochloric acid furnishing some organic chloride, and sulfuric acid causing dehydration of the alcohol. Phosphoric acid generally avoids both these results. Salts that hydrolyze to furnish hydrogen ions are also used, e.g., zinc chloride, aluminum sulfate, ferric chloride, sometimes by the addition of acid to these salts.

The equilibrium point can be displaced to produce more ester than is shown in the tables by increasing the relative amounts of either the acid or the alcohol as desired.

A complicating factor of considerable significance when recovery of the ester is to be made by distillation is the existence of 2-component (binary) azeotropes of constant boiling points with (1) ester and water and (2) ester and alcohol, and 3-component (ternary) azeotropes with (3) ester and water and alcohol, selected data on which are contained in the following table.

Ester [Alcohol]	B.P. °C.	Azeotrope			
			B.P. °C.	Ester %	Other Component %
Ethyl acetate [Ethyl alcohol	77.1 78.3]	a b c	70.4 71.8 70.3	93.9 69.2 83.2	6.1 water 30.8 alcohol {7.8 water 9.0 alcohol
n-Propyl acetate [*n*-Propyl alcohol	101.6 97.2]	a b c	82.4 94.7 82.2	86.0 49.0 59.5	14.0 water 51.0 alcohol {21.0 water 19.5 alcohol
iso-Propyl acetate [*iso*-Propyl alcohol	91.0 82.5]	a b c	77.4 81.3	93.8 40.0	6.2 water 60.0 alcohol ....
n-Butyl acetate [*n*-Butyl alcohol	126.2 117.8]	a b c	90.2 117.2 89.4	71.3 53.0 35.3	28.7 water 47.0 alcohol {37.3 water 27.4 alcohol
n-Amyl acetate [*n*-Amyl alcohol	148.8 137.8]	a b c	95.2 94.8	59.0 ...... 10.5	41.0 water {56.2 water 33.3 alcohol

The ternary azeotrope has the lowest boiling point and in distillation, as long as the three components are present, it distills off first, then the binary azeotrope distills off as long as its components are present. Since esters are not very soluble in water, water can be added to the distillate, and then water plus alcohol are removed. Upon redistillation the ester soon distills off pure.

Many variations in details are used in applying the principles of esterification.

The industrial importance of esterification may be understood from the following remarks on esters, all of the esters made synthetically.

The annual production in the U. S. is approximately: normal, secondary, and isobutyl acetates 100,000,000 lbs., ethyl acetate 95,000,000 lbs., normal, secondary, and isoamyl acetates 3,000,000 lbs., methyl acetate 1,000,000 lbs. These acetates are used largely in the lacquer industry. Cellulose nitrate (nitrocellulose) is used in the plastics (30,000,000 lbs.), lacquer, and industrial and military explosives industries, cellulose acetate in the plastics (20,000,000 lbs.) and lacquer industries, glyceryl trinitrate (nitroglycerin) in the industrial (20,000,000 lbs.) and military explosives industry, cellulose xanthate (viscose) is an important synthetic fiber for textiles. In the specialized field of plasticizers for the plastics and lacquer industries numerous synthetic esters are used, as examples, butyl stearate, diamyl phthalate, dibutyl oxalate, dibutyl phthalate (also for smokeless powder), dibutyl sebacate, dibutyl tartrate, diethylene glycol monostearate, diethylene glycol distearate, diethyl phthalate, dimethyl phthalate, diphenyl phthalate, glyceryl tripropionate, isobutyl phthalate, tributyl borate, tributyl citrate, tributyl phosphate, tricresyl phosphate, triethylene glycol dihexoate, triethylene glycol dioctoate, triethyl citrate, triethyl phosphate, triphenyl phosphate. Methyl methacrylate ester is an important plastic. Ethyl silicate is used to cover concrete, brick and stone with a coating of silicic acid to resist water penetration. Dioctyl phtha-

late is used as a plasticizer in cable and wire insulation, and dimethyl phthalate as an insect repellant. (See **Esters.**) (R.K.S.)

ESTERS, INCLUDING OILS, FATS, WAXES. An ester is a compound, which by reaction with water, **acid** or **alkali**, forms an **alcohol** plus an acid (a salt of the acid is formed when alkali is used). The reverse reaction, namely, reaction of an alcohol plus an acid, accompanied by the elimination of water, is the most important general method of formation of an ester. Of the alcohols concerned with ester composition or formation, the most common are **methyl alcohol, ethyl alcohol, glycol, glycerol, cellulose.** The range of acids important in the study of esters is wider than that of the alcohols, and the importance is determined largely by the point of view. On the scientific side, esters of all acids are important in extending the knowledge of the acid, frequently important in the determination of unknown acids and some are individually important. On the industrial side, esters of **nitric acid** are important in **explosives**, e.g., glyceryl trinitrate (nitroglycerin, dynamite), cellulose hexanitrate (nitrocellulose, guncotton), glycol dinitrate, in **plastics** (pyroxylin and celluloid), **photographic** films, lacquers, **rayon,** and in collodion; esters of acetic, propionic, butyric acids in plastics, photographic films, rayon, lacquers, e g., cellulose acetate, ethyl butyrate; esters of **stearic, palmitic, oleic, linolic** acids, in vegetable and animal oils and fats for food, in paints and varnishes, for soaps, fatty acids, glycerol; esters of certain acids, e.g., salicylic acid methyl ester (oil of **wintergreen**), in odoriferous substances and perfumes. The esters of each acid are listed under the acid, as follows: (1) carboxylic acids: **acetic, benzoic, carbonic, citric, formic, lactic, malic, oleic, oxalic, palmitic, salicylic, stearic, tartaric,** (2) nitrogen acids: **nitric, nitrous, hydrocyanic, cyanic,** (3) sulfur acids: **sulfuric, sulfurous, thiocyanic,** (4) phosphorus acids: **phosphoric, hypophosphoric, phosphorous.** In addition, in the cases of those acids not discussed individually, the following esters are noted:

Ester	Formula	Melting Point	Boiling Point
1. Methyl propionate	$C_2H_5COOCH_3$	....	80° C.
2. Ethyl propionate	$C_2H_5COOC_2H_5$	....	99° C.
3. Methyl normal-butyrate	$C_3H_7COOCH_3$	....	102° C.
4. Ethyl normal-butyrate	$C_3H_7COOC_2H_5$	....	121° C.
5. Methyl iso-butyrate	$(CH_3)_2CHCOOCH_3$	....	93° C.
6. Ethyl iso-butyrate	$(CH_3)_2CHCOOC_2H_5$	....	112° C.
7. Methyl normal-valerate	$C_4H_9COOCH_3$	....	127° C.
8. Ethyl normal-valerate	$C_4H_9COOC_2H_5$	....	145° C.
9. Methyl iso-valerate	$(CH_3)_2CHCH_2COOCH_3$	....	116° C.
10. Ethyl iso-valerate	$(CH_3)_2CHCH_2COOC_2H_5$	....	135° C.
11. Dimethyl malonate	$CH_2(COOCH_3)_2$	....	180° C.
12. Diethyl malonate	$CH_2(COOOC_2H_5)_2$	....	199° C.
13. Dimethyl succinate	$(CH_2COOCH_3)_2$	20° C.	195° C.
14. Diethyl succinate	$(CH_2COOC_2H_5)_2$	....	216° C.
15. Methyl cinnamate	$C_6H_5CH : CHCOOCH_3$	33° C.	263° C.
16. Ethyl cinnamate	$C_6H_5CH : CHCOOC_2H_5$	12° C.	271° C.

Many esters are found in natural materials, and have uses. Such esters are those found in animal fats, e.g., beef fat for tallow, hog fat for lard, fish oils, and in vegetable oils, e.g., olive oil, corn oil, cottonseed oil, linseed oil. Fatty oils are stored in the plant mainly in the seed, e.g., cottonseed, flax seed (linseed oil), or in a portion of the seed, e.g., corn germ, coconut meat (copra when dried), and in the animal organism localized as such, e.g., beef tallow, hog lard, or distributed in the flesh, in milk, e.g., butter fat, or in liver, e.g., cod liver oil. In animal and vegetable oils and fats the predominating esters are glyceryl stearate, palmitate, oleate (an olefin acid), linoleate (a diolefin acid), linolenate (a triolefin acid), ricinoleate (a hydroxy-olefin acid). A few alcohols other than glycerol are found in the esters of animal waxes, e.g., cetyl alcohol (as palmitate) in the head oil of the sperm whale, myricyl alcohol (as palmitate) in beeswax. There are various methods of classification of oils, fats and waxes. The classification presented on the opposite page gives a selected list of members, accompanied by selected physical and chemical constants.

Saponification Number represents the number of milligrams of potassium hydroxide (KOH) required, under specified conditions, to saponify one gram of the sample.

Iodine Number represents the number of grams of iodine absorbed, under specified conditions, by 100 grams of the sample. Hübl solution contains iodine and mercuric chloride in absolute alcohol. Wijs solution contains iodine monochloride in glacial acetic acid.

Titer Test. From the sample, the free fatty acids are made, and then cooled slowly, the temperature being observed by means of a thermometer whose bulb is immersed in the cooling liquid. When turbidity appears in the liquid the temperature remains stationary or rises slightly. The temperature of the top point of the rise is the titer of the sample.

Reichert Meissl Number represents the number of milliliters of decinormal alkali required to neutralize the volatile fatty acid distillate, obtained, under specified conditions, from 5 grams of the sample. For most oils and fats the number is small, of the order of 0.5, but in the case of butter fats is high, between 20 and 34. Coconut oil gives a value between 6.5 and 7.5, palm kernel oil between 5 and 7, and palm oil between 1 and 2.

Drying oils are those which, upon exposure to the air, gradually form a permanent dry film. Esters of linolic and linolenic acids are present in those oils, and the di- and triolefin acid radicals absorb oxygen from the air and produce this film. Linseed and similar oils are used mainly in paints and varnishes. Some fish oils, e.g., salmon oil, also are used in the paint industry.

Edible oils for food and cooking are mainly non-drying or semi-drying oils and fats. The consumption in this field is the largest of all the outlets for oils, fats and waxes. The edible natural fats, butter, lard, tallow, have been supplemented in recent years by processed materials, such as oleomargarine, supplement to butter, and vegetable shortening, supplement to lard. Oleomargarine may be made by separation at a suitable temperature of liquid oleo oil from solid stearin of beef tallow, and then mixing oleo oil, coconut fat and cottonseed oil in the desired proportions and flavoring with butter fat or carefully ripened milk. Vegetable shortening is made from the liquid oils, usually cottonseed, peanut, corn, soy bean, by reaction with **hydrogen** in the presence of finely divided nickel which is later re-

VEGETABLE AND ANIMAL OILS, FATS AND WAXES—A SELECTED CLASSIFIED LIST

* Also known as Tung Oil.

moved at the proper temperature. The gradual addition of hydrogen results in a product of less liquid and more solid, up to the limit of **hydrogenation,** when the product resembles closely beef tallow. At the desired stage the process is terminated, and the product used as shortening or for frying.

By reaction with water, acid or alkali, the oils and fats form glycerol plus fatty acids, which latter separate as salts when alkali is used. Addition of sodium chloride aids in the separation. These salts are soaps, and the ordinary hard soaps are sodium salts of stearic, palmitic, oleic acids. Potassium salts are jelly-like, and are known as soft soaps. Sodium and potassium soaps are soluble in water and yield a froth, known as lather or suds, when agitated in water. Calcium soaps are insoluble in water, and yield no froth upon agitation. When natural hard waters containing dissolved calcium or magnesium compounds, e.g., the bicarbonate, chloride or sulfate, are used with sodium soaps in washing and cleansing, calcium soaps separate as insoluble precipitates in proportion to the amount of calcium and magnesium contained in the water. This represents loss of soap for cleansing purposes as well as diminished froth and the accumulation of undesirable precipitate in the material being cleansed. Aluminum soaps are also insoluble but are used in certain lubricants and greases. Certain soaps of cobalt, manganese, lead, aluminum, are used as varnish dryers. Glycerol is recovered by distillation under diminished pressure (vacuum distillation) of the water or sodium chloride solution portion, after separation of the sodium soaps.

When the sodium soaps are dissolved in water and dilute sulfuric or hydrochloric is added in slight excess, the free fatty acids of the soaps separate as an insoluble oily or fatty portion. These fatty acids may be separated into fractions as desired by fractional crystallization and filtration, and by fractional distillation under diminished pressure. The stearic acid portion is utilized in the manufacture of candles, when mixed with more or less paraffin wax to secure the desired consistency. The oleic acid portion may be hydrogenated to stearic acid, or treated with concentrated sulfuric acid and naphthalene to form a reagent, known as Twitchell's reagent, for converting oils and fats into glycerol plus fatty acids. While much of the soap which is made utilizes oils and fats that are in the edible class, incdible tallow and recovered greases are important sources. (See **Surface-Active Compounds; Esterification.**)

Other uses of oils and fats are for lubrication of machinery, ranging from light spindle oils to heavy greases, and in medicine, e.g., castor oil, chaulmoogra oil, cod-liver oil.

Oils and fats are recovered from seeds by pressing, cold or hot, or by extraction with a volatile solvent and then distilling off the solvent. Butter fat is recovered from milk by centrifuging. Tallow and lard are purified by heating to melting, the finer qualities being those

recovered by less drastic heating and the lower qualities by more drastic heating.

When oils and fats are exposed to air and light, or contain enzymes, rancidity is developed. This is prevented by careful purification of the oil or fat and exclusion of air. Rancidity is hastened in the presence of free fatty acids in the oil or fat. (For further data on individual oils, see articles on **Cocoa, Castor, Coconut, Corn, Cotton, Olive, Palm, Peanut,** and **Soy Bean.**) (R.K.S.)

ESTRIN. Sex Hormones.

ETHANE. Ethane (C_2H_6 or $CH_3 \cdot CH_3$) is a colorless, odorless gas, boiling point —88° C., density 1.36 grams per liter at 0° C. and 760 mm. (specific gravity 1.05, air equal to 1.00), practically insoluble in water, moderately soluble in alcohol, burns when ignited in air with a pale faintly luminous flame, forms an explosive mixture with air over a moderate range, with excess air the products are **carbon dioxide** plus water, with deficiency of air carbon monoxide plus water. Ethane is among the chemically less reactive organic substances. It reacts, however, with **chlorine** (and with **bromine**) to form mixtures of chloro- (and bromo-) substitution compounds (one-half of the chlorine used forms hydrogen chloride). Ethane occurs, usually in small proportions, in natural gas. The fuel value of ethane is very high, 1730 B.T.U. per cu. ft. Ethane may be prepared by reaction of magnesium ethyl iodide in anhydrous ether (**Grignard's reagent**) with water or alcohols. Ethyl iodide (bromide, chloride) is preferably made by reaction of ethyl alcohol and **phosphorus** iodide (bromide, chloride). Important ethane derivatives, by successive oxidation, are (1) **ethyl alcohol** (C_2H_5OH or CH_3CH_2OH), (2) **acetaldehyde** (C_2H_4O or CH_3CHO), (3) **acetic acid** ($C_2H_4O_2$ or CH_3COOH). (R.K.S.)

ETHER. This term is used, with entirely different meanings, in chemistry and in physics. In chemistry it is used to designate a series of compounds which are discussed in this book under the heading **Alcohols and Ethers.** Chemists also use the term ether to designate a particular member of the series, that is, diethyl ether, $(C_2H_5)_2O$. This compound is also known as sulfuric ether, and as ethoxyethane. It is a colorless liquid, of characteristic odor, boiling point 35° C., inflammable and explosive with air when ignited by fire or electric spark. It is slightly soluble in water (1 volume ether in 10 volumes water) and slightly dissolves water (3 volumes water in 100 volumes ether), is miscible in all proportions with alcohol, dissolves **iodine** and many organic substances, e.g., **oils and fats,** no reaction with ordinary acids or alkalis, or with **sodium** or cold **phosphorus** pentachloride. Ether is prepared by treatment of **ethyl alcohol** with concentrated **sulfuric acid** in excess at about 140° C. For use as an **anesthetic,** ether must be scrupulously pure. Ether is used (1) as an anesthetic by inhalation of the vapor, (2) as a **solvent** in the preparation of explosives and of collodion, and in the extraction of **oils, fats, waxes, gums, resins, alkaloids.**

In physics, the concept of the ether had its origin in the necessity for explaining the propagation of light and the existence of electric, magnetic, and gravitational fields of force. When it became evident that **light** is a wave phenomenon, the search for a medium became imperative. While sound does not traverse a vacuum, light does so perfectly; and electric, magnetic, and gravitational attractions are not interrupted by removing the intervening air. Yet all attempts to corral and examine portions of this supposed residual substance and to ascertain its properties by direct observation have totally failed. If the ether is actually a wave-propagating medium, the speed of the waves is such as to imply an extraordinarily great rigidity or a vanishingly small density, or both. (See **Vibrations and Waves.**)

One mode of attack has been to seek for evidence of an "ether drift," that is, a relative motion of matter with respect to the ether through which it moves; just as one traveling through still air experiences a wind. The results of such quests have proved ambiguous. The **Michelson-Morley experiment** gave a completely negative result. So did the Trouton-Noble experiment, which was an attempt to detect the electromagnetic effect of the motion of the electric charges in a **condenser,** as carried by the earth in its orbit. On the other hand, Airy's experiment on the **aberration of light** might be interpreted as indicating that when a transparent substance moves, the ether is dragged along, not with the full speed of the moving matter, but with a fraction of that speed expressed by Fresnel's so-called "coefficient of drag." This fraction is equal to $\frac{n^2 - 1}{n^2}$, in which n is the **refractive index** of the transparent medium; and its validity was further attested by the experiments of Fizeau on the propagation of light in rapidly moving water. The difficulties presented by such conflicting evidence have been avoided by Einstein, who is his theory of **relativity** dispenses with all assumptions as to the supposed stationary ether or motion with respect to it. (See **Anaesthesia.**) (R.K.S., L.D.W.)

ETHER DRIFT. Ether.

ETHYL ALCOHOL. Ethyl **alcohol,** ethanol, "grain alcohol" (C_2H_5OH or CH_3CH_2OH) is a colorless liquid, of pleasant odor, melting point —117° C., boiling point 78.5° C., constant minimum boiling point mixture—distillate—with water 78.15° C., 4.4% water, 95.6% ethyl alcohol, miscible in all proportions with water or ether, soluble in **sodium** hydroxide solution, when ignited burns in air with a pale blue, transparent flame producing water plus carbon dioxide, the vapor forms an explosive mixture with air and may be used in **internal combustion engines** under high compression. Ethyl alcohol reacts (1) with **sodium** metal forming sodium ethoxide, (C_2H_5ONa) plus hydrogen gas, (2) with **phosphorus** chloride, bromide, iodide, forming ethyl chloride, bromide, iodide, respectively, (3) with **sulfuric acid** concentrated, forming at 100° C. ethyl hydrogen sulfate ($C_2H_5OSO_2OH$), at 140° C. diethyl ether ($(C_2H_5)_2O$), at 200° C. ethylene ($CH_2{:}CH_2$), (4) with organic **acids,** warmed in the presence of sulfuric acid, forming **esters,** e.g., ethyl acetate ($CH_3COOC_2H_5$), ethyl benzoate ($C_6H_5COOC_2H_5$) (see various individual acids), (5) with magnesium methyl iodide in anhydrous ether (**Grignard's** solution) forming **methane** as in the case of primary alcohols, (6) with **calcium** chloride to form a solid addition compound ($4C_2H_5OH \cdot CaCl_2$), which is decomposed by water, (7) with **oxygen,** using **sodium** dichromate solution and sulfuric acid, to form **acetaldehyde** (and **acetic acid**), using air, in the presence of acetic bacteria, to form vinegar (dilute acetic acid along with the substances present in the alcohol used, e.g., wine, cider), (8) with **nitric acid** (a) concentrated, free from nitrogen tetroxide, to form ethyl nitrate, (b) dilute to form glycollic acid, (c) concentrated acid containing nitrogen tetroxide (fuming nitric acid) explosive reaction, (9) with **chlorine** (or **bromine**) to form chloral (CCl_3CHO) (or bromal).

The density of pure ethyl alcohol is 0.789, at 20° C., compared with water at 4° C. (the corresponding figure for methyl alcohol is 0.792) and the percentage of ethyl alcohol present in an ethyl alcohol-water solution may be determined from the density of the sample. Anhydrous ethyl alcohol, "absolute alcohol," may be obtained by removal of water by the reaction of the water with calcium oxide and then distilling the alcohol, or by distillation of ethyl alcohol-water with benzene.

Ethyl alcohol is made (1) by **fermentation** of many **carbohydrates**; directly from dextrose or levulose of fruit juices, e.g., grape, apple, and indirectly from sucrose, maltose, starch, cellulose after conversion of the latter group into the former. When starch (usually from corn or potatoes) is used, the starch is changed to maltose by means of diastase of "malt," which is produced by the germination of **barley**. Maltose from starch or sucrose of molasses is fermented by the addition of yeast which generates the **enzymes** maltase (converting maltose to glucose), invertase (converting sucrose to glucose plus levulose), zymase, effective in accomplishing the conversion of glucose to **ethyl alcohol** plus **carbon dioxide** (⅓ of the sugar is changed to carbon dioxide) in dilute solution (not over 18% alcohol). When starch or cellulose of wood is treated with dilute acid heated, dextrose is formed (about 2% of fermentable sugars is present in the waste liquor from the sulfite process of making wood into paper pulp) and this may be fermented by yeast, (2) by absorption of ethylene of coal gas or petroleum gas, and subsequent reaction with water, (3) by reduction of acetaldehyde in the presence of a **catalyzer**. From the solution, ethyl alcohol is separated, recovered and concentrated by fractional distillation. "Proof spirit" is defined by the United States Government as one containing 50% by volume of ethyl alcohol and 50% water, that is, 42.47% by weight of ethyl alcohol and of density 0.930 at 20° C. compared with water at 4° C.

Pharmacology and Medical Uses. The intoxicating agent of alcoholic beverages is ethyl alcohol. It is found in sherry, whiskey, brandy, wine, beer, ale, and all other alcoholic beverages. Considerable knowledge has been acquired about the various effects of ethyl alcohol upon man, and they will be discussed briefly in this article.

In the human body, alcohol is rapidly absorbed from the stomach and upper intestine. It is almost completely oxidized, and in the process energy is released and **carbon dioxide** and water are produced. The heat of combustion of pure alcohol is 7 calories per cc. About 2% of ingested alcohol usually escapes oxidation and is excreted, mainly through the kidneys and lungs.

Once absorbed, alcohol affects nearly every tissue of the body, but particularly the central **nervous system**. Contrary to lay opinion, it is not a stimulant, but a depressant. The feeling of well-being, the expansiveness of personality, impulsive speech and actions are all the result of loss of inhibitions, or removal of the normally restraining influences of the higher cerebral centers. Careful tests have shown that alcohol does not increase either the mental or physical abilities. It is the psychic effect of the drug which results in the individual's estimation of his own performance as greatly improved whereas, actually, his mental reaction time and manual skill are decreased.

On the **cardiovascular system** the chief effect is dilatation of the blood vessels, particularly those of the skin. This results in the commonly observed flushing of the skin following the ingestion of alcoholic beverages, and a feeling of warmth. Actually, however, peripheral vasodilatation and the increased sweating which goes with it result in heat loss, so that the temperature inside the body falls. This fact is particularly important in cold climates, where the irrational use of alcohol to "keep warm" may have serious results.

The **digestive system** is affected in several ways. Moderate concentrations stimulate the flow of saliva and gastric juices which favor digestive processes. This is particularly true of those who enjoy alcoholic beverages. Since the presence of food in the stomach decreases the concentration of alcohol, and therefore lessens any irritative effects, the most desirable way of taking it is with meals. High concentrations are irritative to the digestive-tract mucosa, cause hyperemia and **inflammation** and, in extreme instances, even massive hemorrhage.

Alcohol tends to increase the output of urine, not due to a direct diuretic effect, but because of the accompanying large amounts of fluid usually ingested. Contrary to popular belief, alcohol is not an aphrodisiac. The sexual behavior it provokes follows as a result of loss of inhibitions.

Drunkenness or alcoholic intoxication depends on the concentration of alcohol in the blood. Unlike other foods, it is absorbed unchanged from the gastrointestinal tract and into the circulation. The blood concentration varies greatly depending on the individual's degree of tolerance. Within 5 minutes after ingestion alcohol can be detected readily in the blood. In an abstainer, the concentration gradually reaches a peak and remains high for several hours. In an habitual drinker, the concentration reaches a lower peak more quickly and also falls off rapidly. The blood level which is indicative of intoxication is a matter of dispute. In general, a concentration of 0.20% in blood or urine means some degree of intoxication. Obvious intoxication is present in over 90% of individuals with a blood alcohol concentration of 0.30%, and the fatal range is between 0.50 and 0.80%. The mechanism of tolerance is not well understood. That there is a cross-tolerance to allied hydrocarbon anaesthetics is evidenced by the difficulty of inducing **anaesthesia** with chloroform, ether, or avertin in chronic alcoholics. Addiction to alcohol occurs, but it is unlike morphine addiction in that sudden abstinence need not provoke withdrawal symptoms. The tolerance of the alcohol addict has definite limits—usually only 2 to 4 times that of the occasional drinker.

Acute alcoholic intoxication is manifested by euphoria —a sense of great physical and mental power, noisiness, increased motor activity, progressing to clumsiness, incoordination, staggering gait, a feeling of remoteness, emotional instability, nausea, vomiting, poor control of urination, and finally loss of consciousness, stupor, and profound coma. Emergency treatment directed toward overcoming shock and stimulating respiration may be necessary. Death is rare unless coma persists for many hours, or unless some medical complication such as an acute infection supervenes.

Chronic alcoholism may result in a variety of syndromes, most of which are discussed under their respective headings. Depending on which organ systems are predominantly affected the following disorders may occur: alterations in personality, **delirium tremens**, acute and chronic alcoholic **psychoses** (acute alcoholic hallucinosis, Korsakoff's Syndrome, etc.). Failure to eat an adequate diet results in malnutrition, weight loss, and **deficiency diseases**, particularly **pellagra**, so-called alcoholic **polyneuritis**, and **cirrhosis** of the liver. The treatment of chronic alcoholism is a psychiatric as well as a medical problem. The chronic alcoholic is most often a mental defective or a psychopathic personality. In the latter case, long-term **psychotherapy** directed toward elimination of personal and social maladjustments is necessary for a "cure" to be effective and lasting. Hospitalization is often required, especially in the acute psychoses where a patient's suicidal and homicidal tendencies are a menace to himself and the community. General care, attention to diet, supplementary **vitamins**, and sedation are often valuable adjuvants to psychotherapy. Relapses are frequent, but the prognosis for recovery is better than in morphine addiction.

The therapeutic uses of alcohol are varied, particularly as interpreted by the laity. Externally, it is used as a rubifacient, to cool the skin and promote evaporation of moisture in fevers, to decrease sweating, and to keep the skin dry and resistant in bed-ridden patients.

Injection of alcohol around nerves or ganglia for the relief of pain is carried out in trigeminal neuralgia (**tic douloureux**), in certain cases of **angina pectoris**, and in some patients with inoperable **cancer** associated with intractable pain.

The ingestion of moderate amounts of alcoholic beverages by those who enjoy them is useful in improving the appetite and digestion, particularly in convalescents, and in aged or debilitated individuals. As a remedy for insomnia, a hot toddy at bedtime is a popular and effective remedy. Because of its vasodilatating effect on the coronary arteries of the heart, alcohol is excellent treatment for angina pectoris. The usefulness of alcohol in checking a "cold" perhaps rests more on the side results—for example, the relaxation and drowsiness induced are apt to keep a patient in bed—rather than on any actual pharmacological effects.

Besides its medical uses, ethyl alcohol is used (1) as an important solvent of chemicals and pharmaceuticals, in varnishes, tinctures, perfumes, (2) as an **antiseptic** in surgery, (3) for the preservation of hospital and museum physiological and pathological specimens, (4) in the production of **ether, esters,** and the source of the ethyl group (C_2H_5—) and the ethoxy group (C_2H_5O—), in organic chemical reactions, (5) for the production of vinegar, e.g., from wine, cider, (6) as a liquid **fuel**, clean and relatively safe, with possibility of extensive use in internal combustion engines, (7) in antifreeze solutions (20% by volume ethyl alcohol, 80% water, freezing point 18° F.; 36% alcohol, 64% water, −2° F.; 54% alcohol, 46% water, −29° F.). Stringent government regulations cover the manufacture, use and sale of ethyl alcohol in all forms. Alcohol not for beverage but for industrial purposes is tax-free. Tax-free industrial alcohol is either used under government supervision or, without such supervision, after being completely denatured by the addition of non-potable substances.

Ethyl alcohol may be detected by the formation of iodoform, a treatment with alkali, potassium iodide, and iodine solution.

Anhydrous ethyl alcohol is made from the constant boiling mixture with water (95.6% ethyl alcohol) (1) by heating with a substance such as **calcium** oxide, which reacts with water and not with alcohol, and then distilling, or (2) by distilling with a volatile liquid such as **benzene** (boiling point 79 6° C.), which forms a constant low boiling mixture with water and alcohol (boiling point 64.9° C.), so that water is removed from the main portion of the alcohol; after which alcohol plus benzene distills over (boiling point 68.3° C.), and finally anhydrous ethyl alcohol (boiling point 78 5° C.). Anhydrous ethyl alcohol is demanded for certain purposes as a solvent and reagent, among other applications is that of addition to gasoline or to benzene as motor fuel. In the presence of water, separation into two layers takes place, and the following data apply:

ALCOHOL-GASOLINE MIXTURES

% by Weight		Water Added per 100 Grams Mixture to Cause Separation	% Alcohol of Alcohol-Water Portion in Product
Alcohol	Gasoline		
10	90	0.46 g.	95.6
20	80	1.09	94.8
30	70	1.85	94.2
40	60	2.78	93.5
50	50	3.75	93.0

ALCOHOL-BENZENE MIXTURE

% by Weight		Water Added per 100 Grams Mixture to Cause Separation	% Alcohol of Alcohol-Water Portion in Product
Alcohol	Benzene		
10	90	1.0 g.	90.9
20	80	3.0	87.0
30	70	6.1	83.1
40	60	10.8	78.7
50	50	16.1	75.7

(R.S.M., D.M.H., R.K.S.)

ETHYL CHLORIDE. **Chlorine; Anaesthesia.**

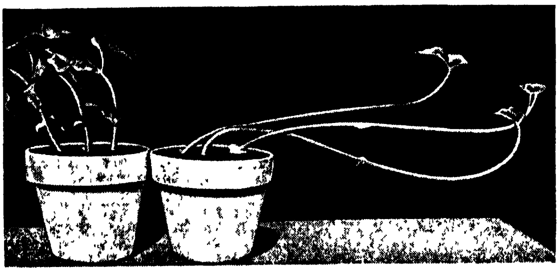
ETHYLENE. Ethylene, ethene (C_2H_4 or $CH_2{:}CH_2$), is a colorless gas, of slight odor, and acts as an anesthetic when inhaled, boiling point −104° C., density 1.26 grams per liter at 0° C. and 760 mm. (specific gravity 0.97, air equal to 1.00), liquid at 10° C. and 50 atmospheres pressure, insoluble in water, burns when ignited in air with a luminous flame, its presence in coal gas is chiefly responsible for the luminosity of the latter, forms an explosive mixture with air, of high fuel value (1615 B.T.U. per cu. ft.). Ethylene reacts (1) with **chlorine (bromine, iodine)**, to form ethylene dichloride ($C_2H_4Cl_2$ or $CH_2Cl{\cdot}CH_2Cl$) (dibromide, diiodide), (2) with **hypochlorous acid (hypobromous acid)**, to form ethylene chlorohydrin ($CH_2Cl{\cdot}CH_2OH$), (bromohydrin), (3) with **hydrogen iodide** or **bromide** (not chloride) to form ethyl iodide (C_2H_5I) or ethyl bromide (C_2H_5Br), (4) with **hydrogen** in the presence of a catalyzer, e.g., finely divided nickel at 150° C., to form ethane (C_2H_6 or $CH_3{\cdot}CH_3$), (5) with concentrated **sulfuric acid** at 160° C. to form ethyl hydrogen sulfate ($C_2H_5HSO_4$) from which ethyl alcohol is readily made, (6) with **potassium** permanganate, to form ethylene **glycol** ($CH_2OH{\cdot}CH_2OH$), although glycol is made preferably from ethylene dichloride or chlorohydrin. Ethylene is made by the removal of water from ethyl alcohol, either by passing over heated bauxite, or by heating with concentrated sulfuric or **phosphoric acid**, and is recovered from gas mixtures in which it is present, e.g., oil-cracking gases where the olefin content may be as high as 35%. Ethylene is used (1) in the preparation of its derivatives, (2) as an **anesthetic,** (3) as a fuel with oxygen for high-temperature flames, (4) as a coloring and ripening agent for citrus fruits and tomatoes. Ethylene chlorohydrin is used as an agent for decreasing the dormant period of seeds. Fuming sulfuric acid is used as a reagent for the absorption and estimation of ethylene in a mixture of gases. (R.K.S.)

ETIOLATION. This is the effect of darkness on a living plant. It is a matter of common observation that plants grown in dark contain little or no chlorophyll and so are nearly white. Green plants placed in darkness lose their chlorophyll. Eventually, when the food reserves are exhausted, the plant dies.

Besides the lack of chlorophyll, plants grown in the dark have other characteristics. In **dicotyledons,** the internodes of the stem become excessively elongated and very slender. The leaves fail to expand normally. In **monocotyledons** the leaves become very long and usually very narrow, but the stem shows little change. Etiolated plants never bear flowers, unless the flower buds are well developed before the plants are darkened.

Internally the tissues are soft and lack strength, the cells being very large and having thin walls. Very little differentiation occurs, the conducting tissues being very much reduced. Leaves which form in darkness show

very little of the structure characterizing a normal green leaf, but are almost entirely composed of loosely arranged **parenchymatous** cells.



Formative influence of light. Bean (Phaseolus) grown ten days in light (left), ten days in dark (right).

The cause of the conditions observed in etiolated plants is not at all understood. The cessation of **photosynthesis** and the consequent inability of the plant to manufacture foodstuffs does not explain the phenomenon, since no etiolation effects are observed in experiments in which photosynthesis is entirely stopped by withholding **carbon dioxide** from a well-lighted plant.

This phenomenon is used to advantage in the growing of certain plants used for salads. French endives are grown in light until a food reserve is stored up, then held in storage, and later forced in darkened rooms. The bleaching of celery is a similar process, produced by covering the leaf petioles with earth or sheltering them with boards or paper. (R.M.W.)

ETIOLOGY. Knowledge of the cause of any disease or abnormal condition. (R.S.M.)

ETTINGSHAUSEN EFFECT. This phenomenon, discovered in 1887, is analogous to the **Hall effect** and appears to be closely related to it. If a strip of metal in which an electric current flows longitudinally is placed in a magnetic field with the plane of the strip perpendicular to the direction of the field, it is found that corresponding points on opposite edges come to different temperatures. If, to one looking along the strip in the direction of the current, and with the magnetic field downward, the decrease of temperature is toward the right, the effect is positive. This is the case with bismuth, in which the phenomenon was first observed by Ettingshausen. The same is true of antimony. nickel, and cobalt; but in iron the effect is negative. (See also **Nernst and Righi-Leduc Effects.**) (L.D.W.)

EUCALYPTUS OIL. Volatile Oils.

EUCLASE. The mineral euclase is a **silicate of beryllium** and **aluminum** corresponding to the formula $Be(AlOH)SiO_4$ which crystallizes in the **monoclinic** system. It has a perfect prismatic cleavage; hardness, 7.5; specific gravity, 3.1; luster, vitreous; is colorless to sea-green or blue. It has been used to a very slight extent for jewelry as its transparent crystals somewhat resemble the aquamarine. Euclase occurs in the Minas Geraes region, Brazil, associated with **topaz** and **beryl**, and also in the Ural Mountains, where it is found in gold-bearing sands. The name euclase is derived from the Greek meaning easiness and fracture, in reference to its easily cleaved crystals. (E.S.C.S.)

EUGENICS. A division of biological science closely related to sociology. It is concerned with the study of human **heredity** and with methods of improving the heritage of human beings.

Sir Francis Galton, a student of human heredity, was a pioneer in suggesting the possibility of securing a better heritage for mankind by the deliberate control of human reproduction. It is evident now that man cannot extend to himself, under his present social system, the degree of control that he applies to his domestic animals, but a few measures have seemed possible. Whether the possibility is more than theoretical is doubtful, but these measures are still advanced as the program of eugenics. They depend chiefly on the birth rate of different classes.

In the United States about 3.4 children per family is the average necessary for the maintenance of the population. This number is equaled only by the portion of the population at the lowest levels of mental development adequate for self-maintenance in society, while families of higher intelligence average far below it. Mental defectives who have to be confined in public institutions are not a serious source of concern, for many of them have no opportunity to reproduce, but, at the level of the low-grade moron, families average slightly more than four children. In the highest levels of the population, too, there is little need for concern. Families average slightly less than three children, but better opportunities probably offset this low figure. The great mass of respectable, self-maintaining, ambitious human beings between these extremes, however, average scarcely a child per family and so are far from maintaining their lines of descent.

The purpose of eugenics to correct this discrepancy demands for its realization some practical means of leveling the birth rate by increase in the upper brackets of society and by decrease in the lower. Sterilization has been suggested for the latter purpose and has been legalized by more than half of the states. It can be applied as a legal compulsion, however, only to institutionalized criminals and defectives, and this application does not reach the parts of society most in need of restriction. To increase the rate of reproduction in the higher middle classes is no easier. Since economic problems are an important cause of the limitation of families, it has been suggested that state subsidies for the care of children would be an aid. Unfortunately practical subsidization in the United States has been forthcoming only as charity and government aid, which have enabled the indigent to continue their overproduction at the expense of their more provident fellow citizens. Education in the serious import of the unbalanced birth rate and in the responsibility of the family to society have also been suggested, but unfortunately the foundations of human existence involve a stronger sense of responsibility to family than to society.

As a result of the lack of feasibility or of promise in the proposed measures of eugenics, the science is in the unenviable position of realizing the needs of mankind for the assurance of its future welfare and improvement, and of being impotent to accomplish any important gains toward the desirable end. Until the individual can be more completely subordinated to society it will undoubtedly remain at this impasse. (A.W.L.)

EUGLENOIDIDA. An order of 1-celled animals. **Mastigophora.** (A.W.L.)

EUHEDRAL. Used by mineralogists to describe a crystalline rock, usually igneous or metamorphic, in which certain of the mineral constituents, usually the **phenocrysts**, have well-defined crystal faces. (See also **Arkose, Subhedral** and **Auhedral.**) (R.M.F.)

EULAMELLIBRANCHIATA. In some classifications an order of **bivalve** mollusks containing the **oysters.** (A.W.L.)

EULERIAN COLUMN. Column.

EULER'S THEOREM ON HOMOGENEOUS FUNCTIONS. This is a statement of a mathematical result concerning a certain type of function.

If $u = f(x, y, z, \cdots)$ is a **homogeneous function** of two or more variables of the nth degree which has continuous first **partial derivatives**, then

$$x\frac{\partial u}{\partial x} + y\frac{\partial u}{\partial y} + z\frac{\partial u}{\partial z} + \cdots = nu.$$

(L.L.S.)

EULER'S THEOREM ON THE EXPONENTIAL FUNCTION. Euler's theorem is a remarkable mathematical result giving a relation between the **trigonometric functions** and the **exponential function.** It may be expressed by the formula

$$\cos x + i \sin x = e^{ix}.$$

(L.L.S.)

EUPHAUSIACEA. A small order of marine **crustaceans.** (A.W.L.)

EUPHORIA. This term describes a feeling of well-being which is not justified by the physical condition of the patient. It is seen in certain mental disturbances, manic depressive **psychoses,** paresis, in the terminal stages of **peritonitis,** and in tuberculosis. (D.M.H.)

EUROPEAN CORN BORER. Insecta, Lepidoptera. A small **moth,** *Pyrausta nubilalis,* whose **larva** bores in the stems of plants, especially Indian corn. The species is closely related to certain North American moths and was first noticed as a pest in the eastern part of the United States about 1920. Since then it has spread half-way across the continent. (A.W.L.)

EUROPIUM. Symbol: Eu. Atomic number: 63. Atomic weight: 152.0. (**Isotopes:** page 290.) Type of compound: Eu_2O_3. Color of salts: Rose. Discovered by Demarçay in 1906. A member of the **cerium** sub-group of the rare earth metals. (R.K.S.)

EURYALAE. Ophiuroidea.

EURYPTERID. Invertebrate Paleontology.

EUSTACHIAN TUBE. A slender canal between the **pharynx** and the middle **ear** of **vertebrates.** It permits the equalization of pressure on the two surfaces of the ear drum. (A.W.L.)

EUTAXIC. A term proposed by Keyes in 1901 for obviously stratified **sedimentary** ore deposits as contrasted with those which are unstratified. The latter he designated as **ataxic.** (R.M.F.)

EUTECTIC. This term is applied by **petrologists** to a discrete mixture of two or more minerals, in definite proportions, which have simultaneously crystallized from the mutual solution of their constituents. The eutectic point is the lowest temperature at any given pressure at which the above physical-chemical process may take place. The eutectic ratio is the ratio by weight of two minerals which originate by the above process.

The term eutectic is used in metallurgy in reference to that particular mixture, of a definite composition, of two or more given substances which has the lowest freezing point. The solid which separates at this temperature has the same composition as the liquid. (R.M.F., F.T.M.)

EUTECTOID. In binary alloy systems a eutectoid alloy is a mechanical mixture of two phases which form simultaneously from a solid solution when it cools through the eutectoid temperature. Alloys leaner or richer in one of the metals undergo transformation from the solid solution phase over a range of temperatures beginning above and ending at the eutectoid temperature. The structure of such alloys will consist of primary particles of one of the stable phases in addition to the eutectoid, for example ferrite and pearlite in low-carbon **steel.** (See **Metals and Alloys.**) (R.H.H.)

EUTHANASIA. Easy or painless death brought on to end a lingering, hopeless, painful disease. (R.S.M.)

EUTHERIA. Mammalia.

EVAPORATION. The evaporation of a liquid consists in the escape from the main body of the liquid of those **molecules** which, in their thermal agitation, are moving with a sufficient speed to break through the **surface tension;** that is, whose **kinetic energy** exceeds the **work function** of cohesion at the surface. Since only a small proportion of the molecules are at any instant located near enough to the surface and are moving in the proper direction to escape, the rate of the evaporation is limited. It is easy to see why it proceeds more rapidly with higher temperature, and why liquids of low surface tension are relatively volatile. Also, as the faster moving molecules emerge, those left behind have less average energy, and the temperature of the liquid is thereby lowered. If the evaporation takes place in a closed vessel, the escaping molecules accumulate as a **vapor** above the liquid. Many of them return to the liquid, such returns being more frequent, the greater the density and pressure of the vapor. Presently the processes of escape and return come to equilibrium; the vapor is then said to be "saturated," its density and pressure no longer increase, and the cooling effect ceases. Even a warm breeze cools the skin because it removes the evaporating perspiration and prevents saturation. (See **Hygrometer, Distillation,** and **Heat of Vaporization.**) (L.D.W.)

EVAPORATOR. Evaporators are used, (1) to concentrate a solution by volatilization of water it contains (as discussed in the article on **Distillation**), and (2) to produce pure water from sea water, or other impure source of supply.

An evaporator system may be single effect, in which the steam is produced from one evaporator, or multiple effect, in which the steam is produced from several evaporators in series. In a multiple effect system the vapor from one evaporator becomes the heating steam in the succeeding. Unusual conditions met in industrial or steam heating plants may require so large a fraction of make-up as to warrant double, triple, or quadruple effect evaporators. The central generating station ordinarily employs single effect and rarely requires more than a double effect system. The ratio $\frac{\text{vapor produced}}{\text{steam used}}$ is about 0.8 for the single effect, 1.5 for the double effect, and 2.5 for the triple effect system. Evaporator feed is sometimes preheated to increase evaporator capacity.

Evaporators are classed as film, flash, or submerged-tube types. The first and last are steam-tube types; in the former the raw water trickles over the hot tubes, in the latter the tubes are entirely surrounded by the water being evaporated. The flash type produces steam by dropping the pressure on water at the saturation temperature. The excess heat flashes part of the water into steam, then the remainder is drawn off, reheated, and again flashed. (F.T.M.)

EVERGREEN. Conifers.

EVOLUTE OF A PLANE CURVE. The evolute of a curve is the **locus** of the **center of curvature** of the given curve.

The **normal** to a curve at a point P is **tangent** to its evolute at a corresponding point Q, so that the **envelope**

of the system of normals to a given curve is the evolute of that curve. (L.L.S.)

EVOLUTION. In astronomy, for the evolution of the planets, see **Solar System.** In mathematics, evolution is the operation of raising a number to a given positive integral **power** (i.e., of multiplying a number by itself a certain number of times). Its two **inverse operations** are **involution** and taking **logarithms.**

In mathematics, the operation of extracting a **root of a number** is sometimes called evolution. It is one of the inverse operations to **involution** (raising to positive integral powers).

In biology, evolution is a process of gradual transformation. In application to living things, it is the process by which their hereditary characteristics are modified through a series of generations, resulting ultimately in the production of new subspecific units and species differing in various degrees from the ancestral stock.

The idea of gradual change in living things as a normal part of their vital processes, and the idea of origin of species through these changes, were expressed in a crude form by the philosophers of ancient Greece, but it was not until 1859, when Charles Darwin published his famous book, the *Origin of Species*, that they were so firmly established as to be a permanent part of science. The idea of evolution now permeates all fields of science. In biology organic evolution, as opposed to special creation of species by a divine power, is regarded as an established principle, although it is still referred to as the theory of evolution.

The evidences of evolution are derived from two sharply contrasted fields, biology and **paleontology.** In the former the subsidiary anatomical sciences, **embryology** and **physiology,** reveal countless details of relationship among living things. All are related in their cellular and protoplasmic structure, and in taxonomic groups within the animal kingdom the resemblance becomes more and more detailed as the lower divisions are approached. Thus all animals resemble each other in metabolic processes, in contrast with plants. Within the kingdom a fairly sharp division into the 1-celled **Protozoa,** the loosely integrated multicellular **Parazoa** containing only the sponges, and the numerous phyla of **Metazoa,** is evident. Among the Metazoa **diploblastic** and **triploblastic** structure, **coelomate** and **acoelomate,** and metameric and unsegmented, mark other progressive divisions. The classification of the entire kingdom expresses all details of relationship. (See **anatomy; classification; tree of life.**)

The interpretation of these relations varies. To the person who is satisfied with the idea of special creation it is no more difficult to believe in the creation of related forms than of unrelated, but several types of evidence lead the biologist to entirely different conclusions. The existence of structurally similar organs (**homology**) adapted to widely different environmental conditions is among these evidences. An example is the group of appendages including the human arm, the flipper of the whale, and the wing of a bird. All are based on the **pentadactyl appendage** although they differ so widely that they are superficially unlike each other. Structures of similar uses but very different structure (**analogy**), such as the wings of birds and insects, indicate that animals may be adapted to a given environment in different ways, hence the many examples of homologous organs such as those mentioned above are strongly suggestive to the scientist that animals have been able gradually to become adjusted to environments different from those of their ancestors through structural modification. The vestigial organs recorded by **anatomy,** such as the human wisdom teeth, are additional evidence. Structures of no value to the individual, sometimes even harmful, can most satisfactorily be explained as persisting remnants of things once useful in an ancestral stage.

Only one biological science, embryology, reveals an actual transition in structure. This transition is the foundation of the recapitulation theory or biogenetic law which postulates that the individual during its development passes through steps representative of ancestral stages in its evolution. The idea must be used with caution, for no embryonic stage can be regarded as precisely like a preceding ancestral form and such conditions as **cenogenesis** are accompanied by correspondingly great modifications in individual development. In some structures, however, a transition occurs that is too closely like the sequence of structures in related groups of animals to be wholly insignificant. The circulatory system of the vertebrates is a particularly good illustration. In an embryonic bird or mammal it is first like that of a fish in many details, then like that of an amphibian, then it resembles the reptilian system, and at last it attains the distinctive development of its own class. This transition involves the formation and destruction of many parts and the remodeling of a structural plan fitted for a gill-breathing animal to form that of a lung-breathing type. Such preliminary stages cannot be explained as necessary to the ultimate pattern of the organic system in all cases. They are much more logically interpreted as remnants of ancestral stages, pointing to the origin of existing forms by evolution from ancestors in which they were definitive adult structures.

Paleontology adds to this evidence a fragmentary record of extinct inhabitants of the world in the form of fossils. These remains are in many cases associated with strata of sedimentary rocks that have enabled geologists to determine a sequence of past ages extending through many millions of years. In the chronology thus established the fossil remains appear also as a sequence, ascending from the simplest forms in the oldest fossil-bearing rocks to man in the most recent periods, with a dominance of various forms of gradually increasing complexity between. In this sequence only invertebrate remains appear in the earlier deposits. Later primitive fishes are found, and still later an age of fishes in which the group gained high development. The succeeding periods are an age of amphibians, an age of reptiles, and finally an age of mammals.

In many cases abundant fossils have made it possible to arrange series of forms leading by very gradual stages from some remote ancestor to an existing species. One of the most famous of these ancestral series is that of the horse. Beginning with a small browsing animal, *Eohippus,* with four toes on the front feet and three on the hind, it passes through the gradual loss of all but one toe on each foot, accompanied by increase in size and by the modification of the teeth for grazing. Sequences of this kind, and the many fossils of animals unlike the present fauna, leave no doubt that the population of the world has undergone tremendous changes, and no reasonable doubt that the changes have been based on the gradual modification of living things.

Accepting the occurrence of evolution, biological science is particularly interested in knowing how such changes have come about. Various theories have been proposed but exact knowledge of the nature of evolutionary change is still lacking.

Two schools of thought were emphasized in the earlier works on evolution following Darwin's contribution, one based on the ideas of the French biologist, Lamarck, and the other on those of Darwin. Lamarck emphasized the reaction of the individual to its environment through the use or disuse of inherited potentialities as a source of modifications. The results of such reaction in the individual body are commonly called acquired characteristics. Lamarck regarded them as the foundation of evolutionary changes through a succession of generations. Darwin's theory of natural selection, on the other hand, emphasized the great variation of heritable characteristics as the basis of evolution through the selective action

of the environment. He pointed out that overproduction is a general tendency among living things. Assuming that variation within species results in some individuals being better equipped than others to meet environmental conditions, he concluded that these well-adapted individuals would have a better chance of surviving and perpetuating their inherited characteristics. He added that these characters would continue a progressive development in succeeding generations, to the ultimate production of new species. This theory is also known as the survival of the fittest.

Many objections have been proposed to both of these theories. Lamarck's idea that change occurs in the individual through reaction to the environment, or by use and disuse, is abundantly supported. We have no reason to believe that such changes are inherited, but whether or not they have some influence on the development of the following generation is less clear. Darwin erred chiefly in assuming the progressive development of selected characters. Apparently natural selection alone can result only in the splitting up of a species or in the contraction of its range of variation, but not in change beyond existing limits of variation. An even more serious objection is that the destruction of surplus individuals is largely accidental, offering no opportunity for the preservation of any particular hereditary characteristics.

One early result of this controversial approach was a futile attempt to establish some influence of body structures on reproductive tissues. The modern approach to this problem accepts the unity of the body and the close coordination of all of its parts, reproductive tissues included, but is still at a loss to prove that reactions of the body to environmental factors during the life of the individual have an effect on succeeding generations.

An important modern contribution is the mutation theory of De Vries, a Dutch botanist. Mutations are abrupt changes from the ancestral range of variation, which breed true, barring further change of the same kind. Mutations have been observed in many plants and animals, including the evening primroses with which De Vries worked, and the fruit fly, **Drosophila,** which has been so important in the study of **heredity.** The recognition of such changes provides a foundation for effective evolutionary change by natural selection, if only it can be demonstrated that some mutations are useful to the individual. Unfortunately most of those that have been observed are of no evident value. Even with the assumption that mutation plus selection may be an adequate explanation of evolution, we are faced with the difficulty of explaining the production of mutations, for they are only a recognized phenomenon of unknown source at present. They have been produced by the action of penetrating rays, such as x-rays and radium emanations, and in some cases by the effect of temperature on the parent animal. Here the problem returns to the interaction of the individual with its environment, and in the normal association of these factors the solution may yet be found.

Selective forces, including natural selection, **isolation** of limited stocks, and the deliberate control of reproduction by human interference (**selection**), may well bring about changes in the complex population of the world, and when associated with hybridization their potentialities are greatly increased. This type of evolutionary change does not, however, explain the initial appearance of diversity, as any adequate theory of evolution must.

Modern investigation of evolutionary processes is closely linked with the science of genetics. In this science many of the observed chromosomal irregularities associated with reproduction account for hereditary changes in organisms, to be classed with those mentioned above. Our ultimate explanation of evolutionary change may well come from studies of correlated environmental and hereditary changes in this field of study. (A.W.L., L.L.S.)

EXACT DIFFERENTIAL EQUATIONS. Ordinary Differential Equations of First Order and First Degree.

EXCESS AIR. The theoretical quantity of air which should supply just that amount of **oxygen** required for chemical union with the molecules of a **fuel** is insufficient for combustion under actual conditions. This is because of the dynamic conditions attending the combustion of fuel in a furnace. In the relatively short time that the fuel and air are together in a region of high temperature, the imperfection of mixing methods, and the presence of the fuel in lumps and large particles, rather than separated molecules, combine to promote incomplete combustion unless there is an excess of oxygen over that which is actually needed. The excess air is ordinarily given as a percentage of the theoretical requirement, and the amount employed is determined by the degree of technological control of combustion practiced, the surface exposure of the fuel, i.e., whether the fuel is gaseous, atomized, powdered, or lump, and the perfection of design of the furnace and firing equipment. Excess air is shown by the presence of oxygen in the products of combustion. When no more than a trace of **carbon monoxide** is present in the flue gas, the excess air may be found by the following formula:

$$\text{Excess air} = \frac{20.9R}{CO_2(R+3)} - \frac{R+2.37}{R+3}.$$

In this formula the symbol R is employed to denote the "fuel ratio" of the coal, this being the ratio of carbon burned to hydrogen burned with oxygen from the air. The carbon is the total revealed by the ultimate analysis, less any fraction left unconsumed in the refuse. The hydrogen part of the ratio is ordinarily the free hydrogen, but if much sulfur is contained, the hydrogen should be corrected as follows:

$$H = \text{total hydrogen} - \frac{(\text{total oxygen} - \text{sulfur})}{8}.$$

R is generally from 50 to 25 for anthracite, 20 to 16 for semi-bituminous, and 16 to 12 for bituminous coals.

Fuels ranging from the hard and nearly smokeless anthracite through intervening ranks down to the brown and woody lignite have their combustible elements combined in many different ways but, strangely enough, the air required to produce a thousand heat units from any coal is very nearly a constant amount. This fact may be turned to good account in rapid determination of the air needed for combustion if the calorific value of the coal is known. Trial computations show that 1 lb. of combustion air is theoretically required for each 1340 B.T.U. produced in complete combustion, for any coal chosen.

The excess air requirements vary widely with the type of installation. Lump coal, fired by stokers, will usually be completely burned with the use of 50% of excess air, whereas in the hand-fired stokers, up to 100% may be necessary, and undoubtedly a great deal of domestic coal firing, unaided by technological information or experience, is carried out with from 150% excess air upwards. Pulverized coal and fuel oil may be satisfactorily fired with 5–15% excess air, and gaseous fuels fired with the aid of well-designed burners may be so effectively mixed with air that no excess air is needed. (F.T.M.)

EXCHANGE, TELEPHONE. This designates the territory served by a group of central offices for which there is normally no extra charge for service. Thus the various offices of a given city constitute an exchange. (See **Telephony.**) (L.R.Q.)

EXCITATION. This term is used in several applications in electrical engineering. It is customary to speak of the field excitation of **dynamo** machines, meaning the current or voltage of the field circuit. In electron tube circuits the signal which excites a stage is commonly called the excitation. Thus in a radio **receiver**, the signal picked up by the **antenna** supplies the excitation for the first stage, the output of the first supplies the excitation for the next and so on. (L.R.Q.)

EXCITING CURRENT. This is the current which supplies the **core losses** and magnetizing current for a **transformer.** When the transformer is supplying a load this excitation current is one component of the total input, the other being the component which balances the load current. In an electrical distribution system having many customers' transformers (see **Electric Power Transmission**) which often have a low or zero load, the exciting current becomes quite important because of the line losses and poor power factor caused by it. (L.R.Q.)

EXCRETION. The removal of the waste products resulting from the chemical transformation of materials in the body.

The **oxidation** of materials derived from foods for the release of energy may produce carbon dioxide and water whether the compound oxidized is a **protein,** a **carbohydrate,** or a **fat,** but since proteins contain **nitrogen** and other elements in addition to **carbon, hydrogen,** and **oxygen,** they also give rise to more complex waste products. The chief nitrogenous wastes of animals are **urea** and **uric acid.** The elimination of all of these compounds and other substances of like derivation is excretion.

Many small animals, including both protozoans (**Protozoa**) and more complex forms, apparently discharge these wastes from the surface of the body generally, while in others a special **excretory system** occurs. Even in those forms which have a complex excretory system, any moist surface directly or indirectly exposed to the medium surrounding the animal is favorable for the diffusion of materials into or out of the body, and so may carry on excretion. The wastes passed out in this manner are largely carbon dioxide and water, although the discharge of water may also take out dissolved solids. Thus the lungs of a terrestrial vertebrate eliminate carbon dioxide and the sweat glands of the skin of some animals discharge water with other materials, including nitrogenous wastes, in solution. By far the greater part of the complex wastes is eliminated by the **excretory system.**

In complex animals other organs than those directly involved in the elimination of wastes may play an important intermediary role. The circulatory system of the **vertebrate,** for example, transports all wastes from the tissues where they are formed to organs which act upon them and finally to the centers which remove them from the body. The liver removes some substances, including complex organic compounds resulting from the destruction of old red blood cells, and discharges them in the **bile** by way of the intestine. It also transforms **ammonia** and **amino acids,** resulting from the oxidation of proteins, into urea which is returned to the blood to be removed by the **kidneys.**

Wastes are stored in the body during embryonic life and immature stages of some animals to be discarded with the tissues containing them at birth or transformation. The **allantois** of bird embryos serves as a reservoir for wastes and the **fat body** of insect larvae serves a similar purpose according to some observers. (A.W.L.)

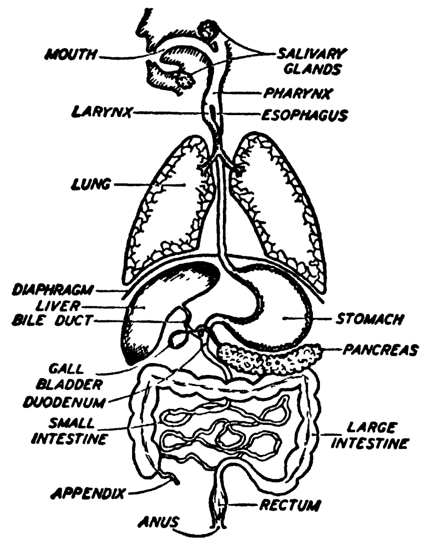
EXCRETORY SYSTEM. An organic system whose principal or only function is the removal of complex wastes from the animal body.

Some animals lack an organized excretory system, discharging wastes from the surface of the body generally, but others, even among the 1-celled animals, have special excretory structures. The **contractile vacuoles** of protozoans are supposed to carry out this function.

In the flatworms a special excretory system based on the flame cell appears. Flame cells are large and hollow, with a group of cilia projecting into the cavity whose movement drives out the liquid discharged by the cell. The cavity of each flame cell joins a small duct and these ducts converge to form larger ducts which ultimately open at the surface of the body. Flame cells emptying by ducts into a vesicle connected with the caudal end of the alimentary tract also occur in **rotifers.**

Roundworms have two slender excretory canals along the sides of the body which unite to empty by a single pore near the anterior end.

In the segmented worms the body cavity becomes involved in excretion. Two forms of tubes, the coelomoducts and nephridia, open from the **coelom** to the exterior in these worms. These organs are segmentally arranged ciliated tubes with a funnel-shaped inner end and a minute opening externally. They are variously associated in the excretory organs of different species and in some do not open into the coelom but are provided with cells much like flame cells which are called solenocytes.



(From Carlson and Johnson's The Machinery of the Body, University of Chicago Press.)

Arthropods of different classes have special excretory structures, including the coxal glands of **scorpions,** said to be derived from coelomoducts, and the Malpighian tubules of insects. The latter are slender tubules opening into the alimentary tract at the caudal end of the stomach and blind at their other end.

The occurrence of **solenocytes** in the lancelets of the phylum **Chordata** is unusual in this phylum, since in the true vertebrates a pair of kidneys are the chief excretory structures. They are developed from intermediate mesoderm (**Embryology.**) The excretory unit in these organs is a minute tubule which has in its primitive form a ciliated funnel leading from the coelom. At their lateral ends the series of tubules unite to form a duct which grows back to empty into the **cloaca.** The tubule is associated with a knot of blood vessels near the coelomic opening (the nephrostome). In a more advanced stage of development excretory tubules lack the nephrostome and have the wall expanded to form Bowman's capsule, embracing the knot

of blood vessels which is called a glomerulus. This unit, known as a renal corpuscle, is found in the kidneys of most vertebrates. The tubule leading from it is also specialized for the removal of wastes from the blood.

Three pairs of kidneys are found in different vertebrates and appear in succession in the embryos of the higher classes, the reptiles, birds, and mammals. In cyclostomes and embryos of fishes and amphibians the kidney are pronephroi, lying well forward in the body and made up of tubules of the primitive type. The pronephroi are vestigial in embryonic reptiles, birds and mammals. Functional kidneys in these embryos and in the adults of cyclostomes, fishes and amphibia are the mesonephroi, lying behind the pronephroi and made up of closed tubules. As they develop, these tubules connect with the duct formed by the pronephroi; this duct is then called the mesonephric or Wolffian duct. In adult reptiles, birds and mammals the mesonephroi are replaced by the metanephroi, lying still farther back. Their tubules develop in a mass of tissue surrounding a blind diverticulum of the mesonephric duct.

The connection of the excretory ducts with the cloaca persists in many vertebrates but in the true mammals this passage splits to form a dorsal rectum and a ventral urogenital sinus which receives the Wolffian duct. An expanded reservoir, the urinary bladder, developed ventrally in connection with the cloaca, ultimately receives the ducts of the metanephroi, while the remainder of the mesonephric duct persists in the male as the main duct of the testis. The relations of all these parts differ greatly in animals of different groups. In all animals with metanephroi the ducts leading from the kidneys are called the ureters and a separate duct from the urinary bladder to the exterior is the urethra.

The association of excretory and reproductive passages is considered under the **Urogenital System.** (A.W.L.)

EXOCYCLOIDA. An order of sea urchins. **Echinoidea.** (A.W.L.)

EXOGENETIC. A general term designatng all surficial, or near surficial, geologic processes such as: erosion, deposition, **secondary enrichment** of ore bodies, etc. Not particularly applicable to volcanism. (R.M.F.)

EXOPHTHALMIC GOITRE. **Thyroid Gland.**

EXOPHTHALMOS. An abnormal protrusion of the eyeball most often seen in **Graves' disease.** (See **Thyroid Gland.**) (D.M.H.)

EXOPODITE. **Biramous Appendage.**

EXOPTERYGOTA. Insects whose wings appear in the immature stages as external flaps. These insects have gradual or incomplete metamorphosis, hence the term embraces the **Paurometabola** and **Hemimetabola** of some writers. (A.W.L.)

EXOSKELETON. **Skeletal System.**

EXOTHERMAL CHANGE. **Thermochemistry.**

EXPANDER, VOLUME. This is the part of the communication circuit designed to expand the volume range back to the original value as it is normally compressed for transmission. (See **Compressor.**) (L.R.Q.)

EXPANDING UNIVERSE. **Spirals.**

EXPANSION. The term expansion refers commonly to a process in which a constant mass of a substance undergoes an increase in volume. In thermal expansion this is brought about by raising the temperature of the substance. Expansion processes are of great importance in engineering. Thus, the power derived from steam engines and turbines and internal combustion engines is produced as a result of expansion of gases and vapors. (See **Ratio of Expansion.**) Expansion of metals with increase of temperature is the operating principle of **thermometers, thermostats,** and many other useful devices. On the other hand the increase in size of pipes as they are heated creates a problem in engineering design. (See **Expansion Joint.**)

Each molecule of a body of matter in any state appears to monopolize a certain amount of space which, while it cannot be accurately called the volume of the molecule, does represent the contribution of that molecule to the volume of the whole body. The molecules are in a state of agitation; and it is to be expected that the space which any molecule monopolizes, or keeps clear for itself, will be larger, the greater the amplitude of its oscillations (just as one may make a posthole larger by working the post to and fro in different directions). We have here the fundamental reason for the expansion of bodies with rise of temperature. (See **Heat.**)

The rate of expansion of a substance with temperature has been expressed by several different "expansion coefficients." The one now usually employed, as regards change of volume, may be defined as the rate of change of the volume of a body of the substance with respect to temperature, divided by its volume at the zero of temperature:

$$\alpha_v = \frac{dv}{dt}/v_0. \qquad (1)$$

Thus for iron at ordinary temperatures, α_v is about 0.000036 per degree centigrade. While not strictly constant, it is nearly enough so for ordinary purposes By integration of (1) the volume at any temperature t is

$$v = v_0(1 + \alpha_v t). \qquad (2)$$

These statements apply alike to solids, liquids, and gases. The fact that the coefficient α_v is nearly the same for all gases is expressed by **Charles's law.**

For solids we may also define a linear expansion coefficient, relating to the change in any one dimension l, thus:

$$\alpha_l = \frac{dl}{dt}/l_0, \qquad (3)$$

from which the value of that dimension at any temperature t is

$$l = l_0(1 + \alpha_l t). \qquad (4)$$

Since for an isotropic solid the volume at a given temperature is proportional to the cube of any dimension, it is easy to show that

$$\alpha_v = 3\left(\frac{l}{l_0}\right)^2 \alpha_l. \qquad (5)$$

But for moderate temperatures l and l_0 are nearly equal, hence, practically, the volume coefficient is three times the linear. Thus the linear coefficient for iron is about 0.000012 per degree centigrade.

If from the known thermal capacity of a solid we deduct the calculated energy corresponding to change of thermal agitation in all the atomic degrees of freedom, and also the energy expended in expansion against the external pressure, the remainder may be taken as representing the work of expansion against cohesion, and hence used as a means of calculating the "internal pressure" arising therefrom. (See **Adhesion and Cohesion.**)

Much progress has been made in the preparation of substances having expansion coefficients of desired value. Thus "platinite" (54% iron, 46% nickel) has practically the same coefficient as glass and may therefore

be used for lead-wires in vacuum tubes; while "invar" (64% iron, 36% nickel) has a linear coefficient of only 0.0000008 per degree centigrade, and is therefore suitable for clock pendulums. (L.D.W., F.T.M.)

EXPANSION JOINT. Metals constituting pipes have the property possessed by all materials of expanding with increase of temperature. Were they constrained to a fixed length, a reaction equivalent to the force required to compress the pipe through a deformation equal to the prevented expansion would be set up. For all but very short steam lines this force is too large to incorporate in the piping system. The same force would be present, theoretically, in the short line, but the supports would have enough elasticity to take the small expansion. In long lines the expansion is permitted by the use of suitable joints and bends.

Both packed and packless expansion joints are used for saturated steam at pressures up to 250 lbs. per sq. in. High temperature has a deteriorating effect on packing; however, packed joints have been designed for high temperature by protecting the packing by air-cooled sleeves. Expansion joints take up expansion at one point by allowing relative motion of the two sections of pipe connected by the joint. Usually one pipe end is anchored by a rigid connection to the body of the joint but occasionally the double slip joint in which both pipe ends are free to move in the joint is used.

When expansion is to be taken by the flexibility of the pipe itself various forms of pipe bends are used. This way of caring for expansion is free of the temperature-pressure limitations of the expansion joints and also of any maintenance work such as the repacking of joints. Consequently, it has been the standard for boiler and turbine leads and for long runs of high-pressure piping of all sorts. Its principal drawbacks are the added friction losses, the expense of fabrication (most bends are special jobs), and the space required. (F.T.M.)

EXPANSION OF DETERMINANTS BY MINORS. Determinants.

EXPANSION OF FUNCTIONS IN SERIES. In many mathematical investigations it is desirable to express a given function in a certain special form of representation known as an infinite series One important use of such representation is for the calculation of numerical values of functions, as, for instance, in the preparation of mathematical tables.

Taylor's formula with a remainder for a **function** of one variable is:

$$f(a+h) = f(a) + hf'(a) + \frac{h^2}{2!}f''(a) + \frac{h^3}{3!}f'''(a) + \cdots + \frac{h^{n-1}}{(n-1)!}f^{(n-1)}(a) + R_n.$$

Various formulae have been given for R_n, some of which will be given presently.

If $f^{(n)}(x)$ is finite in an interval (a, b) for all values of n and if $R_n \to 0$ when $n \to \infty$, then the formula gives a **convergent infinite series (power series)** for the function $f(x)$.

Lagrange's form of the remainder is:

$$R_n = \frac{h^n}{n!}f^{(n)}(a+\theta h), \quad \text{where } 0 < \theta < 1.$$

Cauchy's form of the remainder is:

$$R_n = \frac{h^n(1-\theta)^{n-1}}{(n-1)!}f^{(n)}(a+\theta h), \quad 0 < \theta < 1.$$

Let $|f^{(n)}(x)| \leqq M_n$ in the interval to be considered; then

$$|R_n| \leqq \frac{|h|^n}{n!} \cdot M_n.$$

When $a = 0$, Taylor's formula becomes Maclaurin's formula:

$$f(h) = f(0) + h \cdot f'(0) + \frac{h^2}{2!}f''(0) + \cdots + \frac{h^{n-1}}{(n-1)!}f^{(n-1)}(0) + R_n.$$

If $R_n \to 0$ as $n \to \infty$, we obtain a power series expansion for $f(h)$ in powers of h

Some important expansions of elementary functions in power series are:

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \cdots,$$

convergent for all values of x;

$$\log_e(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \cdots,$$

convergent for $-1 < x \leqq 1$;

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots,$$

where x is in radian measure, convergent for all values of x;

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots,$$

(x in radian measure), convergent for all values of x;

$$(1+x)^m = 1 + mx + \frac{m(m-1)}{2!}x^2 + \frac{m(m-1)(m-2)}{3!}x^3 + \cdots,$$

convergent for $-1 < x < 1$, when m is not a positive integer

Taylor's formula with remainder for a function of two variables is:

$$f(a+h, b+k) = f(a, b) + hf_x(a, b) + kf_y(a, b) + \frac{1}{2!}[h^2 f_{xx}(a, b) + 2hkf_{xy}(a, b) + k^2 f_{yy}(a, b)] + \cdots + R_n,$$

or in symbolic form:

$$f(a+h, b+k) = f(a, b) + \left(h\frac{\partial}{\partial x} + k\frac{\partial}{\partial y}\right)f(a, b) + \frac{1}{2!}\left(h\frac{\partial}{\partial x} + k\frac{\partial}{\partial y}\right)^{(2)}f(a, b) + \frac{1}{3!}\left(h\frac{\partial}{\partial x} + k\frac{\partial}{\partial y}\right)^{(3)}f(a, b) + \cdots + \frac{1}{(n-1)!}\left(h\frac{\partial}{\partial x} + k\frac{\partial}{\partial y}\right)^{(n-1)}f(a, b) + R_n,$$

where

$$R_n = \frac{1}{n!}\left(h\frac{\partial}{\partial x} + k\frac{\partial}{\partial y}\right)^{(n)}f(a+\theta h, b+\theta k), \quad 0 < \theta < 1.$$

(L.L.S.)

EXPANSION REAMER. Reaming.

EXPANSION SHOE. Bearing.

EXPECTED VALUE. If $p_1, p_2, \cdots p_n$ are the **probabilities** that a random variable x should assume values $x_1, x_2, \cdots, x_{n-1}, x_n$, then the expected value of x, $E(x)$, is defined as

$$p_1x_1 + p_2x_2 + \cdots + p_nx_n$$

where $\sum_{i=1}^{n} p_i = 1$, and the x's are **discrete.** In case x is a **continuous** variable, then

$$E(x) = \int_{x=a}^{x=b} xP_x\,dx$$

where $P_x\,dx$ is the probability function of x, and the range of x is from a to b. The expected value should not be confused with the **mean**. Similarly we define the expected value of x^2, x^3 as

$$E(x^2) = \int_{x=a}^{x=b} x^2 P_x\,dx, \quad \text{and} \quad E(x^3) = \int_{x=a}^{x=b} x^3 P_x\,dx.$$

In the case of a discrete variable the integrals are replaced by summations. (L.A.A.)

EXPERIMENTAL ERROR. When experiments are repeated, the **statistics** calculated from each **sample** vary. If these variations are not attributable to any cause, they are called the experimental errors. This is particularly true in the **analysis of variance** where the experimental error is the portion of the variation remaining after all known causes of variation are removed. (L.A.A.)

EXPLICIT FUNCTION. If a **function** is defined by a relation between the **variables** giving an **equation** expressing one variable directly in terms of the other without the necessity of solving the equation, the function so defined is called an explicit function. (L.L.S.)

EXPLOSIVES. Explosives are substances that, either pure or with admixture of other substances, react rapidly with the production of local high temperature and the generation of large volumes of gases. The power from the expansion of the gases is utilized for propelling charges or for **blasting** objects, usually for military or industrial purposes. Gunpowder was the first explosive to be used. Not until 1865, when Abel perfected a process for washing nitrocellulose, "guncotton" (cellulose hexanitrate) thus making it safe to store and use, and in 1867, when Nobel discovered that nitroglycerine (glyceryl trinitrate) could be rendered safe by absorption in a porous material such as kieselguhr, were safe explosives available. In 1886, Nobel gelatinized these two explosives, nitrocellulose with nitroglycerine, and at the British government laboratory these were gelatinized with **acetone.** Such an explosive is in very general use as a propellant.

Black powder (gunpowder) consists of an intimate mixture of finely divided solids, 75% **potassium** nitrate, 15% **carbon,** 10% **sulfur.** Powders for sporting guns contain a slightly larger percentage of potassium nitrate (75 to 78%), smaller percentage of carbon (15 to 12%), and a variation in sulfur from 9 to 12%. Mining or blasting powders, where large volumes of gas are desired may have 14 to 21% carbon and 13 to 18% sulfur. When ignited, potassium nitrate supplies oxygen for the combustion of explosives, of carbon to carbon dioxide and of sulfur to sulfur dioxide. One gram of powder yields 250 to 300 milliliters of gas measured at 0° C. and 760 mm. pressure. The heat evolved per gram is 500 to 700 calories, and the temperature of the explosion is estimated at 2700° C.

In explosives of the smokeless powder type, that is, composed of nitrocellulose-nitroglycerine-trinitrotoluene, the material composing the explosive furnishes oxygen for its own combustion when exploded. One volume of nitroglycerin produces by explosion 1300 volumes of gas, measured under ordinary conditions or 10,000 volumes at the temperature of explosion. The speed of the explosive wave in various explosives is as follows:

Explosive	Speed of Explosive Wave Meters per Second
Nitroglycerin	1300
Dynamite	2700
Hydrogen plus oxygen	2800
Nitrocellulose	3800 to 5400
Picric acid	6500
Ethyl nitrate	
(a) In rubber tube covered with cloth	1600
(b) In glass tube	2500

For comparison:

	Speed of Sound Wave
Hydrogen plus oxygen	515

Nitrocellulose is soluble in **acetone,** ethyl acetate (see **Esters**), **nitrobenzene** or **benzene,** insoluble in water, alcohol, ether, **acetic acid,** or nitroglycerin; when treated with **iodine** dissolved in **potassium** iodide solution followed by **sulfuric acid,** turns yellow (**cellulose** similarly treated turns blue); when treated with sodium **sulfide** solution or **ferrous** chloride solution, decomposes and is thus treated when it is desired to destroy the explosive. When carefully washed, nitrocellulose may be transported in the wet condition in wooden boxes placed inside zinc boxes, which are then hermetically sealed. Nitrocellulose may be ignited and burned in the open air without explosion. The ignition temperature of various explosives is as follows:

Explosive	Ignition Temperature
Nitrocellulose (not compressed)	220 to 250° C.
Nitroglycerine (explosive at 240° to 250°)	218
Black powder	288
Mercury fulminate	200

In order to produce an explosion it is usually necessary that a **detonator,** such as mercury fulminate, be used to set up the explosive wave. The explosive wave may be transmitted through a solid body with which portions of the explosive are in contact, as is shown by setting up a row of dynamite cartridges from 30 to 70 cm. apart. When the end cartridge is detonated the others are successively exploded by transmission of the explosive wave through the solid support.

Nitrocellulose is made by reaction of **cotton** with concentrated **nitric acid** in the presence of concentrated **sulfuric acid** (so-called "mixed" acid). The product is carefully washed free from acid with soda, and in composition is an **ester** (not a nitro-compound) cellulose hexanitrate, containing 13% of **nitrogen** and 85% insoluble in ether-alcohol mixture. Less highly nitrated celluloses, soluble in ether-alcohol mixture, are made and used for other purposes, for example, in plastics, collodion and photographic films.

Nitroglycerin is made by reaction of **glycerol** with nitric acid and sulfuric acid, in a process similar to that for nitrocellulose. The product is also an ester, glyceryl trinitrate, a colorless to yellow liquid, 23.4% nitrogen, freezing point 13° C., very sensitive to shock and dangerous to handle. Nitroglycerin is used as dynamite by absorbing in a porous material, such as kieselguhr, which is chemically inert, or wood pulp, which reacts in the explosion. Dynamite is safely handled and transported, and the explosive power of the contained nitroglycerin is practically unchanged upon detonation.

COMPOSITION OF VARIOUS DYNAMITES

1.	Nitroglycerin	72–75%
	Kieselguhr	24.5
	Sodium carbonate	0.5
2.	Nitroglycerin	40%
	Sodium nitrate	45
	Wood pulp	14
	Magnesium carbonate	1
3.	Nitroglycerin	20%
	Sodium nitrate	36

Ammonium nitrate	25 %
Roasted flour	18.5
Sodium carbonate	0.5

Safety explosives, used in coal mining, are designed to diminish the danger of igniting the mine gases. These are made of such materials that the rise in temperature upon explosion is relatively small, and the safety in use is thereby increased. Liquid carbon dioxide, upon fracture of a calibrated disk, allows safe expansion of gas with minimum breakage of coal.

COMPOSITION OF VARIOUS SAFETY EXPLOSIVES

1.	Ammonium nitrate	37%
	Potassium nitrate	34
	Nitrobenzene	29
2.	Ammonium nitrate	82%
	Dinitrobenzene	18
3.	Ammonium nitrate	92%
	Trinitrotoluene	4
	Flour	4

High explosives are used for blasting purposes and in bombs, shells, and mines, where great shattering effect is desired.

COMPOSITION OF VARIOUS HIGH EXPLOSIVES

1. Dynamite

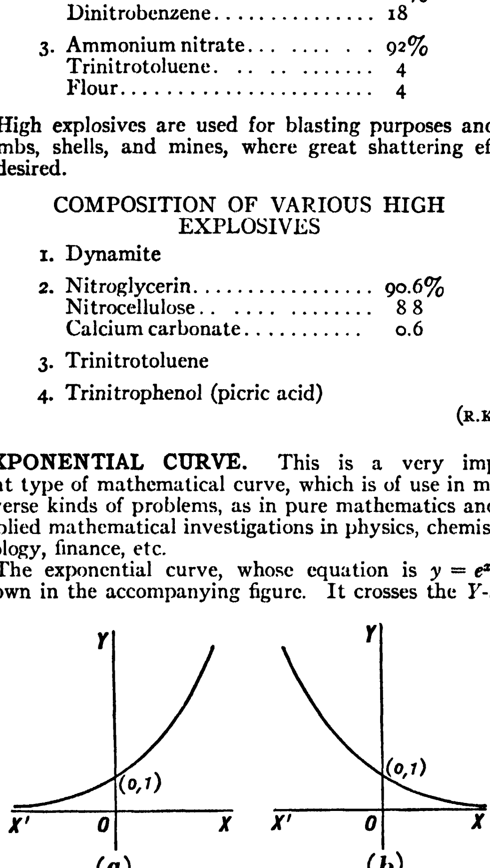
2.	Nitroglycerin	90.6%
	Nitrocellulose	8 8
	Calcium carbonate	0.6

3. Trinitrotoluene
4. Trinitrophenol (picric acid)

(R.K.S.)

EXPONENTIAL CURVE. This is a very important type of mathematical curve, which is of use in many diverse kinds of problems, as in pure mathematics and in applied mathematical investigations in physics, chemistry, biology, finance, etc.

The exponential curve, whose equation is $y = e^x$, is shown in the accompanying figure. It crosses the Y-axis



Exponential curve.

at the point (0, 1), is **asymptotic** to the X-axis on the left, and rises more and more steeply on the right. The graph of $y = a^x$ $(a > 1)$ will be similar to that of $y = e^x$, except of different steepness.

The exponential curve, whose equation is $y = e^{-x}$, is also shown in the figure. It is the same as the preceding, except reversed in position.

The graph of $y = ae^{bx}$ or $y = a \cdot c^x$ will be similar to that of $y = e^x$, except that it will cross the X-axis at (0, a), and will have a different steepness (slope). (L.L.S.)

EXPONENTIAL EQUATIONS. An equation in which the unknown is involved as an **exponent** is called an exponential equation.

Simple exponential equations can be solved by taking **logarithms** of both members and equating them, and solving the resulting **algebraic equation.** (L.L.S.)

EXPONENTIAL FUNCTION. An exponential function is a **transcendental function** of the form $y = a \cdot b^x$, where a and b are **constants** ($b \neq 0$ or 1), and x is the **variable**; it has a constant base and a variable **exponent.**

It is often represented in the standard form $y = ae^{cx}$, where e is the Napierian base, and a and c are constants. (L.L.S.)

EXPONENTS. **Powers and Exponents.**

EXPOSURE. Exposure is defined as the product of the illumination on the sensitive material and the time during which the material is exposed to this illumination or

$$E = it.$$

The unit of measurement is the candle-meter-second, which represents an exposure of 1 second to a source having a light intensity of 1 candle at a distance of 1 meter from the surface of the sensitive material.

Since the time is constant when a sensitive material is exposed in the camera, light reflected from the various parts of the subject produces exposures which are more or less proportional to their own brightnesses. The words "more or less" are used advisedly because the scatter of light within the lens prevents an exact proportionality between the exposures and the brightnesses of the corresponding parts of the subject.

The exposures on the sensitive material depend upon (1) the brightnesses of the subject, (2) the time, and (3) the amount of light transmitted by the lens. The brightnesses of the subject depend upon (1) the lighting, that is, the amount of light received by the different parts of the subject, and (2) by the reflectances of the subject. Thus the side of a house in shadow receives less light than the side in direct sunlight and the white house reflects more of the light than the dark shrubbery at its base. The time, of course, depends upon the timing of the shutter and its efficiency. (See **Shutters.**) The amount of light transmitted by the lens depends upon (1) the relative aperture (f#) and (2) its construction, which determines the loss from absorption and scatter.

To produce a photograph in which the brightness differences of the original are properly rendered it is necessary that the exposures produced by these brightnesses result, upon development, in the density differences necessary for a good print. For satisfactory tone reproduction in the print, the minimum exposure for a given sensitive material is the exposure at that point on the D log E curve at which the gradient is 0.3 of the average gradient over a log E range of 1.5. (See **Sensitometry.**) The reciprocal of this exposure is a measure of the sensitiveness or "speed" of the sensitive material.

The time of exposure in making a photograph depends upon (1) the brightness of the optical image and (2) the sensitiveness (speed) of the sensitive material. However, since it is difficult to measure the brightness of the lens image, the time of exposure is frequently said to depend upon:

1. *The subject.* (a) Light, highly reflecting subjects, such as beach and snow scenes, distant landscapes, (b) dark objects, such as shrubbery, alleys, interiors, etc., (c) shaded objects, portraits in the shade, etc.
2. *The illumination.* (a) Time of day, (b) time of year, (c) bright, cloudy, dull.
3. *The f/number* of the lens used in making the picture.
4. *The sensitivity, or speed, of the film or plate,* i.e. the reciprocal of the exposure necessary to produce a negative from which a satisfactory print can be made. (C.B.N.)

EXPOSURE METER. Instruments used in measuring light for the purpose of determining the proper exposure are known as exposure meters. Exposure meters designed for determining camera exposures may be divided into three classes:

1. Those which measure the ***light reaching the subject*** by the time required to darken a light-sensitive paper. These, formerly quite popular, are now obsolete.

2. Those which measure the ***light reflected from the subject*** visually. These are now nearly obsolete.

3. Those which measure the light reflected from the subject (or in some cases that falling on the subject) with light-sensitive photocells.

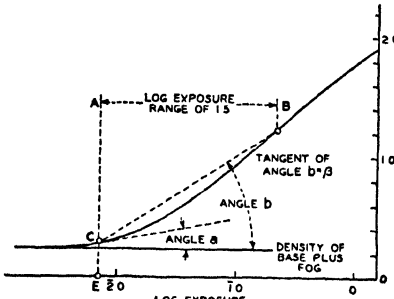
Meters of this last-mentioned type consist of a photocell which transforms the light falling on it into an electrical current and a microammeter which indicates on a dial the electrical current produced by the cell. The dial is graduated either in exposures or in foot-candles from which the exposure is calculated by movable scales.

Ordinarily the meter is held to face the subject so as to measure the total, or integrated, brightness of the entire scene. In this case, the exposure is determined principally by the highlights, since these reflect the most light, and care must be taken not to include too much of the sky, for example, or the rest of the subject will be underexposed. Exposures determined from the total amount of light reflected from the subject may lead to underexposure when the subject is generally light but contains dark objects, particularly if these are small and near to the camera. On the other hand, a subject which is generally dark but contains a small well-lighted area may be overexposed. In cases such as these it is best to measure the light reflected from that part of the subject which is of the greatest importance. This is done by proceeding to the area in question and measuring the light reflected from it alone. With most meters this means that the reading should be made from a distance no greater than the area whose brightness is to be measured.

Methods of determining the exposure from the light reading, or of dealing with exceptional subjects, vary with the different meters. For such information the literature of the manufacturer should be consulted. (C.B.N.)

EXPOSURE-DENSITY RELATIONSHIP. The response of a sensitive material, as shown by the relationship between density and exposure, is usually represented by a curve in which density is plotted against the *logarithm* of the exposure. This curve is known as (1) the *D log E curve;* (2) the *H & D curve,* after Hurter & Driffield, two English investigators who were the first to plot such curves; and (3) as the *characteristic curve* since it indicates the principal characteristics of a sensitive material insofar as the relationship between exposure, development and density is concerned.

The *D* log *E* curve may for convenience be divided into three portions (see figure), although with many



(*Neblette's Photography, 4th Ed.*)

negative materials the different portions are not readily discernible and the exposure range of the **sensitometers** now in general use is too short to include much, if any, of the upper portion. The lower portion, concave to the log *E* axis, is termed ***period of increasing gradient*** (slope) or "toe" portion. Within this range of exposure the increase in density is greater than the increase in log exposure. This part of the curve is sometimes called the period of underexposure but this is true only in the sense that greater exposure is required for proportional representation in the ***negative.*** Parts of this portion of the curve may be used in general photography without producing the effect of underexposure in the ***print.***

The central portion of the curve is approximately straight and is termed (1) the ***straight-line portion,*** (2) the ***period of constant gradient*** (constant slope) and (3) the ***period of proportional representation.*** Over this exposure range, density is proportional to log *E*. As density is, by definition, the logarithm of the opacity, it is clear that within this exposure range the opacities are proportional to the exposures which produced them. In other words, the opacities of the negative are proportional to the exposures produced by the different brightnesses of the subject; hence, proportional representation.

The upper portion of the curve is convex to the exposure axis, thus density increases less and less with increased exposure. This portion of the curve was termed by Hurter & Driffield the period of overexposure. This period terminates at the maximum density and is followed by the period of reversal in which increased exposure results in progressively lower density. The exposures required on negative materials for both the reversal period and for the maximum density are so great that these parts of the curve are seldom included in published *D* log *E* curves. This omission is of no consequence as this part of the curve is of no use in practice. (C.B.N.)

EXTENSION SPRING. **Springs.**

EXTRACTION. Extraction is the process of separation of a desired constituent from the other constituents of a mass. The term, as generally applied, refers to: 1. Mechanical extraction or expression, in such cases as the expression of vegetable oils from seeds by the application of high pressure. The material to be pressed is sometimes placed in layers between cloths which are folded at the edges to prevent expulsion of solid material during compression, and sometimes the material is fed to the annular space between a pair of interfitting slightly tapered compression rolls. The oil and press cake residue are collected separately. 2. **Solvent** extraction, in such cases as the recovery of oils from oil-bearing material. The material is placed in a porous container and subjected to treatment with solvent. The solvent containing some dissolved material passes through the porous membrane, leaving the undissolved residue in the container. The principle of counter-current (see **Dissolving**) extraction may be utilized in consecutive containers, or the solvent may be vaporized from the solution, condensed onto the material, and, by means of a syphon in the apparatus, withdrawn periodically to the solution compartment below, as in the Soxlet type of apparatus. When a third substance is of different solubility in two nonmiscible liquids, this substance may be separated from the solution of lower concentration by shaking with the more powerful solvent, and then separating the two liquid layers. The desired substance may be recovered from the solution by evaporation of the solvent. The effectiveness of separation is increased by the use of a given amount of extracting solvent in successive smaller portions rather than by a single extraction with the total amount.

Example. Upon shaking one volume of liquid *A* **plus** one volume of liquid *B*, suppose a concentration **ratio** of $\frac{1}{10}\frac{(\text{conc. in } B)}{(\text{conc. in } A)}$ of the third substance *C*.

Concentration Ratio $\frac{B}{A}$	Volume Ratio $\frac{B}{A}$	Amount of C in		Fraction of C in	
		B	A	B	A
10	1	$10 \times 1 = 10$	$1 \times 1 = 1$	$\frac{10}{11} = 0.91$	$\frac{1}{11} = 0.09$

Upon shaking one volume of liquid A plus one-half volume of liquid B, and, after separation, shaking one volume of liquid A (containing the residue of C) plus one-half volume of liquid B.

	Concentration Ratio $\frac{B}{A}$	Volume Ratio $\frac{B}{A}$	Amount of C in		Fraction of C in	
			B	A	B	A
First Extraction	10	0.5	$10 \times 0.5 = 5$	$1 \times 1 = 1$	$\frac{5}{6} = 0.83$	$\frac{1}{6} = 0.17$
Second Extraction	10	0.5	0.17×0.83	0.03	0.14	0.03
Combined	.....		...		0.97	0.03

A single equal-volume extraction would, therefore, remove 91% of C from A, whereas a double half-volume extraction would remove 97%.

$$\frac{\text{Concentration of solute in liquid } A}{\text{Concentration of solute in liquid } B} = \text{Approximately constant at a given temperature}$$

(See **Solvents.**) (R.K.S.)

EXTRACTION CYCLE. Extraction cycle refers to any arrangement whereby steam is bled from a turbine at one or more pressures for any purpose whatsoever; i.e., feedwater heating, process steam, heating steam, etc. The terms "bled steam" and "extracted steam" may be used synonymously, as may also "bleeder point" and "extraction point."

There are two types of extraction, i.e., extraction at constant steam pressure and extraction at whatever pressure exists in the **turbine** at the extraction point. Extraction at constant pressure requires that an extraction valve gear be provided to regulate casing pressure at the extraction point. This is necessary because, not only would the extraction pressure vary with different amounts of extracted steam demanded, but varying loads on the turbine would cause the casing pressure at the extraction nozzle to vary. The extraction valve gear is often complicated by the use of a control or pilot valve to operate the main extraction valve. Turbines equipped with extraction valve gear are naturally more expensive than the simpler forms which have no pressure governing on the extraction lines. Industrial use of extracted steam often requires that the pressure of the bled steam be kept constant. Also, industrial use of the extraction turbine differs from central station practice in that frequently a large portion of the total flow is extracted, whereas in the power plant only a small fraction of the total is used for feedwater heating. (F.T.M.)

EXTRACTS. Extracts, or essences, are solutions of flavoring substances, mostly **volatile oils,** dissolved in alcohol or in water. (R.M.W.)

EXTRAEMBRYONIC MEMBRANES. A series of structures developed in connection with the embryos of vertebrates but not as parts of the body itself. They relate the embryo to its environment in several ways. These membranes are the **allantois, amnion, chorion, serosa,** and **yolk sac.** (A.W.L.)

EXTRANEOUS ROOT OF AN EQUATION. In the process of the **solution of equations,** they are often transformed into other derived equations, and one of the derived equations may be readily solved. It sometimes happens that one or more **roots** of the derived equation will satisfy the original equation and also that one or more roots of the derived equation will not satisfy the original equation.

An extraneous root of an equation is a value which satisfies a derived equation but does not satisfy the original equation.

Extraneous roots are liable to occur in solutions of **fractional equations** or **radical equations,** or in **trigonometric equations.** (L.L.S.)

EXTRATHECAL ZONE. The projecting tissue about the base of a **coral polyp,** from which young polyps develop. (A.W.L.)

EXTRATROPICAL CYCLONE. Wave Cyclones.

EXTRA-UTERINE PREGNANCY. Pregnancy.

EXTRUSIVE ROCK. Effusive.

EXUMBRELLA. The upper or convex surface of the body of a **jellyfish** or other **medusa.** (A.W.L.)

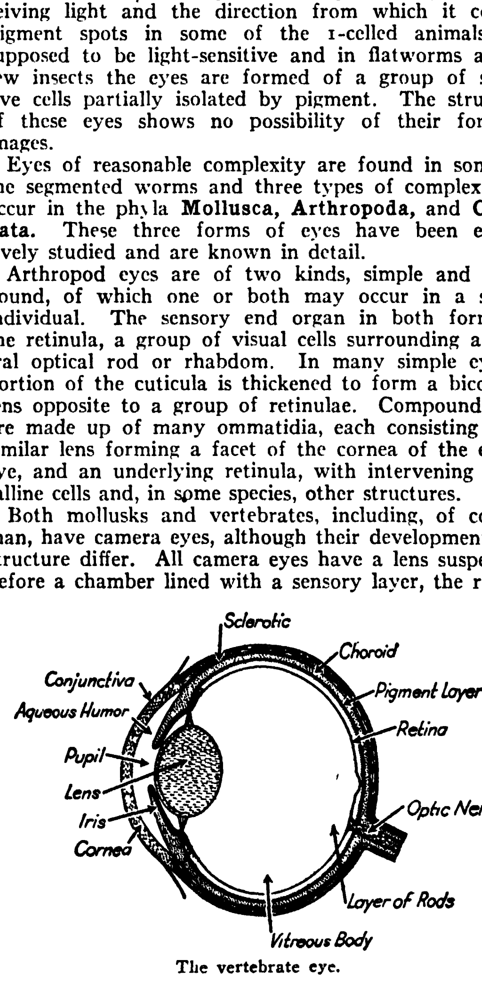
EYE. A sensory organ which is stimulated by light, particularly an organ whose stimulation results in the formation of a mental image of the objects from which the light is reflected or radiated.

Although most eyes enable the animal to form visual images, that is to see in the usual sense of the word, some light-sensitive organs are capable only of perceiving light and the direction from which it comes. Pigment spots in some of the 1-celled animals are supposed to be light-sensitive and in flatworms and a few insects the eyes are formed of a group of sensitive cells partially isolated by pigment. The structure of these eyes shows no possibility of their forming images.

Eyes of reasonable complexity are found in some of the segmented worms and three types of complex eyes occur in the phyla **Mollusca, Arthropoda,** and **Chordata.** These three forms of eyes have been extensively studied and are known in detail.

Arthropod eyes are of two kinds, simple and compound, of which one or both may occur in a single individual. The sensory end organ in both forms is the retinula, a group of visual cells surrounding a central optical rod or rhabdom. In many simple eyes a portion of the cuticula is thickened to form a biconvex lens opposite to a group of retinulae. Compound eyes are made up of many ommatidia, each consisting of a similar lens forming a facet of the cornea of the entire eye, and an underlying retinula, with intervening crystalline cells and, in some species, other structures.

Both mollusks and vertebrates, including, of course, man, have camera eyes, although their development and structure differ. All camera eyes have a lens suspended before a chamber lined with a sensory layer, the retina.



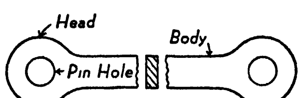
The vertebrate eye.

In front of the lens is another chamber and in front of that a transparent cornea which acts as a lens in terrestrial animals. The eye is insulated by a heavily pigmented layer which surrounds it except where the lens is suspended and extends in front of the lens as the iris. The iris, activated by muscles, controls the size of its central opening, the pupil, through which light enters the eye. Light passing through the lens is focused on the retina in a sharp image and the varied stimuli acting on nerve endings result in a definite mental picture. Such eyes are provided with muscles which direct them toward objects to be observed. They also have muscular focusing devices which move the lens in relation to the retina or vice versa, or control the curvature of the lens as in the human eye.

The action of the different kinds of eyes results in different kinds of **vision.** (A.W.L.)

EYE BAR. The eye bar is a heat-treated tension member formed from a single piece of steel. The finished eye bar consists of a body having a rectangular cross-section and two circular heads containing holes for **pins,** which are used to connect the eye bar when it forms part of a structure.

In the fabrication of an eye bar the ends of a steel plate, of the correct cross-sectional area and length, are heated and **upset** to form the heads. The heads are next rolled to remove any unevenness resulting from the upsetting operation. While the ends are still hot, holes are punched out which are smaller in diameter



Eye bar.

than the finished pin holes. The bars are then subjected to special heat treatment which produces a high tensile strength. After cooling, the pin holes are bored to exact size simultaneously.

Eye bars make excellent tension members since the heat treatment enables them to carry higher tensile loads than the ordinary built-up steel members. As the eye bar is a very slender member it cannot be used where there is a possibility that it will have to carry compressive **stress.** These members are used in the cable anchorages of suspension bridges as well as for tension members of trusses. Eye bar chains have been used in preference to wire cable for suspension bridges. The tension members of cantilever **bridges** are often composed of eye bars. (C.W.C.)

EYE BOLT. **Screw Fastenings.**

EYE OF STORM. At the center of a hurricane there is usually a very small area in which winds are light and the sky nearly clear. This is known as the eye of the storm. A similar "eye of the storm" sometimes exists in temperate-zone cyclones. (P.E.K.)

EYELID. A fold of skin which can be drawn over the eye in **vertebrates** above the fishes. Three eyelids are the maximum. These are an upper and lower lid and a third eyelid or nictitating membrane which passes between the others and the eyeball from the inner to the outer margin of the eye. The eyelids contain glands whose secretion lubricates the apposed surfaces of the lids and eyeball, and in the mammals bears a row of stiff hairs, the cilia or eyelashes. (A.W.L.)

EYEPIECE. The lens, or system of lenses, which is closest to the eye in an optical instrument such as a **telescope** or a **microscope** is known as the eyepiece or ocular The eyepiece is usually a magnifying device used for the purpose of detailed examination of the real image formed by the objective of the instrument. It is usually designed to act as a collimator to the light from the objective so that the light from each point of the image formed by the objective emerges in parallel or nearly parallel rays. Hence in using a telescope or microscope in proper adjustment, the eye should be focused as though looking at a distant object.

The simplest type of eyepiece is either a simple convex or concave lens, of relatively short focus, so placed as to serve as a magnifier for the image formed by the objective. The use of such simple eyepieces is shown in the diagrams in connection with the article on telescopes. Because of the **spherical** and **chromatic** aberrations of the simple lens of short focus, a combination of lenses is usually employed as an eyepiece. The two most common types of compound eyepieces are the

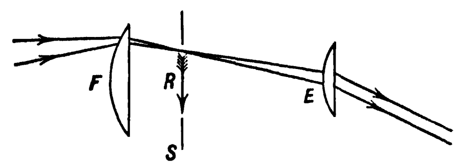


Fig. 1. Eyepiece.

Huygens (Fig. 1) and the Ramsden (Fig. 2). In these eyepieces the lens *F* is known as the fie'd lens and the lens *E* as the eye lens. The Huygens eyepiece is placed slightly inside the focus of the objective and

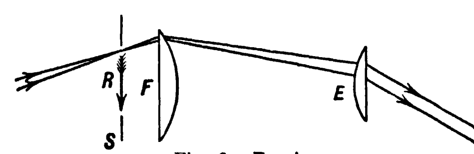

Fig. 2. Eyepiece.

the field lens of the eyepiece forms a real image *R* in the plane *S* from which the rays emerge parallel from *E*. In the Ramsden type the field and eye lenses combine to render the light from the real image *R*, formed in the plane *S* by the objective, parallel upon emergence from the eyepiece. Since the Huygens type eyepiece is placed inside of the principal focus of the objective, a reticle or **filar micrometer** cannot be used, although a reticle may be placed inside the eyepiece itself in the plane *S*. The Ramsden type, on the other hand, is focused directly upon the plane of the real image from the objective and a reticle or micrometer may be placed in this plane. Eyepieces of the Ramsden type, which are simple magnifiers focused upon the real image from the objective, are known as positive eyepieces; while eyepieces placed inside the principal focus of the objective, as in the case of the Huygens type, are known as negative eyepieces. There are many other types of positive and negative eyepieces which will be found discussed in treatises on optical instruments.

Both the positive and negative eyepieces give a view of the image from the objective in the same orientation as that image is formed. This means that the observer will see the image of a distant object inverted. While this is no disadvantage in microscopes and in astronomical telescopes, it is intolerable in a telescope or field glass to be used for observation of distant terrestrial objects. The simple concave lens, as used in the so-called Galilean telescope or opera glass, gives an erect image of a distant object. To avoid the aberrations of the simple concave lens various "erecting systems" are used in terrestrial telescopes. Some of these erecting systems employ prisms, as in the case of binoculars, or complicated systems of lenses. (W.K.G.)

EYRA. **Cat.**

F

F LAYER. Ionosphere.

F/SYSTEM. A method of designating the relative aperture of photographic lenses. The f number expresses the ratio of the diameter of the effective diaphragm aperture to the focal length of the lens. Thus, with a lens having an effective diaphragm of 1" and a focal length of 8", the ratio is 1:8 which is written $f/8$. Following the recommendation of a committee of the Royal Photographic Society of Great Britain, at ratios greater than 1:4 ($f/4$) lenses are marked so that the exposures increase as the power of 2. Thus:

f/number..........	4	5.6	8	11.3	16	22
Relative exposure...	1	2	4	8	16	32

The difference in exposure for two f/values is the difference in the squares of the numbers. The difference in exposure, for example, in $f/4$ and $f/16$ is

$$\frac{16^2}{4^2} = \frac{256}{16} = 16$$

(C.B.N.)

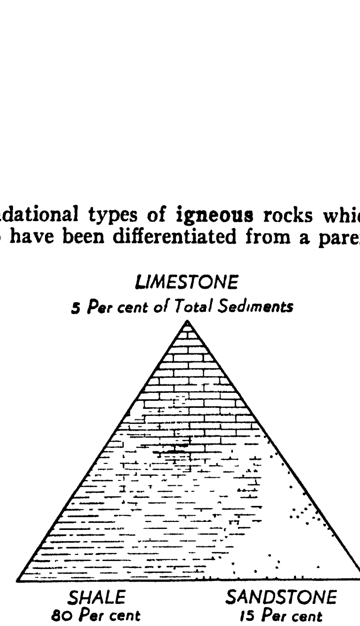
FABRIC. In geology, the term proposed by Cross, Iddings, Pirsson and Washington, in 1902, for the shapes and arrangement of crystals in an igneous rock (Compare with **texture** and **structure.**) Best defined as the arrangement of the constitute constituents in a rock, i e., flow fabric in **lava**, **stratification** or **bedding** in **sedimentary** rocks, **foliation** in **metamorphic** rocks. (R.M.F.)

FABRICATION. Fabrication is the action of constructing or forming a **structure** composed of a number of separate elements which must be joined together in one way or another, according to a definite plan. The common methods of engineering fabrication include fusion methods, such as **welding**; **adhesion**, exemplified by gluing and **soldering**; and pinned connections, illustrated by bolting, riveting, and doweling. Fabrication will also include those operations necessary upon the several elements in order to fit them for assembly; also such trimming, polishing, or adjusting operations as will put the complete structure in its final shape. Included in this category are operations like **drilling**, **shearing**, **milling**, polishing, plating, etc. (F.T.M.)

FACE. The anterior and ventral part of the head, bearing the mouth, eyes, and in vertebrates the nose. (A.W.L.)

FACEPLATE. Lathe.

FACIES. In geology, the sum total of the inorganic and organic characteristics of a sedimentary formation. Obviously, different facies of a **sedimentary** formation (sedimentary time unit) are of the same age; but similar sedimentary facies may represent different formations. Fossils may be useful in determining the age of a facies, provided the types of organisms have not changed with the change in habitat, which, in the case of marine sediments (such as **limestones** or **shale**) they usually do. The term facies is also used to designate gradational types of **igneous** rocks which are supposed to have been differentiated from a parent **magma**. (R.M.F.)



Illustrating the relative abundance of the three principal types of sedimentary rocks and their intergradations, or facies. (*Field, Outline, Barnes & Noble*)

FACING. Lathe.

FACSIMILE TRANSMISSION. This is the transmission by electrical means of any graphic material such as pictures, printed matter, maps, etc. There are three methods of transmission in use, transmission by radio, by land telephone lines and by submarine cable. Each of these introduces its own problems, but the fundamentals of the system are the same for all, the material must be broken into sequential elementary parts which may be transmitted by electrical means and then the parts converted back into a graphic presentation at the receiver. To be specific let us discuss the transmission of a picture although it should be kept in mind that exactly the same procedure applies to any graphic material. The picture is broken into the sequence of elemental parts by the process of scanning. This may be done by mounting the picture on a revolving drum and projecting a very small beam of light on or through it. The light is reflected (or transmitted) to a **phototube**, the light and hence the phototube output being proportional to the picture density. The light is moved along the picture (parallel to the axis of the drum) at such a rate that it displaces axially its own width for each revolution of the drum. Thus the spot of light progressively covers every spot on the picture. The output of the phototube is an electrical breakdown of the picture, and is then modified for transmission. For radio and land lines this means **modulation** upon a suitable **carrier**. There are several methods of doing this but these are merely details of the system. For submarine cable transmission the signal is amplified by d-c amplifiers and fed directly to the cable since these cables cannot handle high frequencies. At the receiving end the modulated signal is demodulated and fed to the recorder. This varies with different systems but two types are in wide use. One depends upon a variable light on a photographic paper or film. The light is varied in different ways, one being to use a specially constructed gas-filled lamp whose intensity varies with the signal, others use light valves, but in each case the result is a spot of light whose intensity varies with the picture focused on the paper. There are some direct-developing papers, but others require a development process after removal from

the receiver. The other method of recording is to utilize a paper sensitized to electrical current passage and to pass the received signal current (after detection, of course) through it. Regardless of the method of recording it is necessary for the receiver to be synchronized with the transmitter. Sometimes this is accomplished by depending upon the stability of the power systems and the use of synchronous motor drives; other methods involve the transmission of synchronizing pulses periodically. Facsimile transmission has a wide field of application in the transmission of news pictures, legal documents, maps, etc. (L.R.Q.)

FACTOR ANALYSIS. Factor analysis is a technique by which a functional relationship of the form $z = a_1x_1 + a_2x_2 + \cdots + a_Nx_N$ in N variables may be replaced by a functional relationship of the form $z = A_1F_1 + A_2F_2 + \cdots + A_jF_j$ where $j < N$. Usually many variables will be replaced by a very few factors which include all these variables. Spearman in his first approach assumed all mental functions were explainable in terms of a general factor and special specific factors. Another example may be considered from the field of physical growth of a person. Using eight variables as a beginning it was found that these could be replaced by two factors, a general physical growth factor and a body type factor. Factor analysis is of value in psychology. Its limitations are, first, that the equation for z is linear in each variable or factor and, secondly, the factors are identified subjectively in the final analysis. (L.A.A.)

FACTOR OF SAFETY. The factor of safety is a number expressing the relation between the utmost endurance of a structural part, or of a complete structure, to the maximum actual demand that may be expected ever to be made upon it. But the factor of safety is not merely some ratio to allow for inaccuracies, lack of knowledge, or absence of confidence. Indeed, it has a very definite rational basis which becomes more apparent as the conditions which govern the factor of safety become known. Factor of safety has many different forms, a few of which will be given below. It represents a combination of the allowances necessary to be made in the use of practical data. The factor of safety will often include a factor which is not so much one of safety, but one of making due allowance for factors known to be present, but not definitely computable. If the engineer could definitely specify the usage and the care to which his product would be put, a large element of the so-called factor of safety would not be necessary. It must include allowance for unavoidable shocks or jars which might be expected during the working life of the structure. The material used may not be homogeneous in character, or uniform in all deliveries. Then there is always the desire to be well on the safe side when, due to failure of some part, life will be endangered. Usually, the factor of safety, at least for machine parts, is taken as the ratio of the **ultimate strength** claimed or accepted for the material, to the working stress used for design, and presumably reached under maximum design loading. When failure is measured by excessive deformation, the factor of safety might well be based on the elastic limit. Likewise, for elements subjected to repeated reversals of stress, the endurance limit should replace ultimate strength. In most old, well-organized fields of design, professional and standardizing societies have undertaken to specify working stresses for the commonly used materials, thus indirectly covering the factor of safety.

Factors of safety do not always bear this name; for example, the safety of a masonry **dam** against overturning is contained in a computed ratio of the overturning moment due to water pressure, divided by the stabilizing moment of the masonry weight. Safety in aircraft design is contained in a carefully and scientifically determined "load factor" made up in accordance with certain rules promulgated by a governmental bureau. (See **Load Factor.**) (F.T.M.)

FACTOR THEOREM OF ALGEBRA. If $x - r$ is a factor of a **polynomial** $P(x)$, then $x = r$ is a **zero** of the **polynomial function** $P(x)$, and $x = r$ is a **root** of the **polynomial equation** $P(x) = 0$; conversely, if $x = r$ is a zero of the polynomial $P(x)$, or is a root of the equation $P(x) = 0$, then $x - r$ is a factor of $P(x)$. (L.L.S.)

FACTORIAL DEVELOPMENT. A method of determining the time of development, due to Alfred Watkins (1895). The time of appearance of the image is multiplied by a factor to obtain the time of development required for a given degree of development. The method is quite reliable with negatives which have been correctly exposed but leads to underdevelopment of overexposed negatives and overdevelopment in cases of underexposure. Factorial development has become practically obsolete as sufficient light cannot be used with panchromatic materials to enable the first appearance of the image to be seen. (C.B.N.)

FACTORIAL NOTATION. **Binomial Formula.**

FACTORING. To factor a **polynomial** means to find polynomials of lower degree than the given one whose **product** is the given polynomial.

By reversing the special **product formulae,** we obtain methods for factoring.

A polynomial with a common monomial factor may be factored by use of the formula

$$ax + bx + cx = x(a + b + c).$$

The difference of two squares may be factored by use of

$$x^2 - y^2 = (x + y)(x - y).$$

Trinomials which are perfect squares may be factored by use of

$$x^2 + 2xy + y^2 = (x + y)^2, \quad x^2 - 2xy + y^2 = (x - y)^2.$$

Trinomials of the form $x^2 + qx + r$ may be factored by use of

$$x^2 + (a + b)x + ab = (x + a)(x + b).$$

Trinomials of the form $px^2 + qx + r$ may be factored by use of

$$acx^2 + (ad + bc)x + bd = (ax + b)(cx + d).$$

The sum or difference of two cubes may be factored by use of

$$x^3 + y^3 = (x + y)(x^2 - xy + y^2),$$
$$x^3 - y^3 = (x - y)(x^2 + xy + y^2).$$

Polynomials may often be factored by grouping of terms and applying the preceding methods.

The process of **synthetic division** is often useful in factoring. (L.L.S.)

FACULAE. **Sun.**

FADING. The fading of radio signals is inherent in the transmission of such signals and at best can only be partially compensated for in the receiver by **avc** circuits, **diversity** reception, etc. The compensation may often be made entirely satisfactory if the fading is of the simplest type, but if it is selective, compensation is not always satisfactory. Radio waves going out from the transmitter travel along various paths to the **receiver,** some of the waves travel along the ground, others are reflected from the **ionosphere.** In the broadcast band fading is usually caused by signals which have been reflected from the ionosphere combining vectorially with signals which have traveled along the earth (these are called respectively **sky wave and ground wave**). The

sky wave does not return to the earth near the transmitter so there is no fading in this region, and at great distances from the transmitter the ground wave has died out so again there is no fading due to this cause. In the intermediate region both waves may be present and if the phase of the two signals is such that they cancel fading results. Since the ionosphere is continually changing, the phase of the reflected sky wave may cause cancellation at one instant and addition of the signals at the next. Different frequencies travel somewhat different paths in the ionosphere so the time to reach the receiver is different for the different sideband frequencies. Thus one frequency may reach the receiver to add to the ground wave, while another may cancel. This produces what is known as selective fading and the output of the receiver is badly distorted. It should be realized that this is an effect of the transmission and not a characteristic of a given receiver. Both types of fading may be produced by two sky waves which have traveled different paths from the transmitter to the receiver. This is the cause of fading at the very high frequencies where the ground wave does not get far enough from the **transmitter** to cause any trouble. (L.R.Q.)

FAHLBAND. A Scandinavian term used by miners to describe **metamorphic** rocks containing richly disseminated ore minerals. (R.M.F.)

FAHRENHEIT SCALE. **Temperature Scales.**

FAILURE. The inability of a **structure** or a structural member to perform its proper function causes a condition known as failure. This condition may be the result of sudden fracture as in the case of brittle materials or the excessive **deformation** of ductile materials. Another cause of failure is a lack of equilibrium between the external **loads** and resisting forces such as exists in structures which fail by sliding or overturning. (C.W.C.)

FAIRED. An object is said to be faired if it is constructed to streamline shape, or has attached to it supplementary bodies which cause it to assume a shape of some degree of excellence of streamlining. The term has its major usefulness in aircraft nomenclature where many instances of fairing of parts in the exposed windstreams are present. Fairing of exposed struts, wheels, cabins, etc., has done much to reduce wind drag and increase performance. Sometimes the part is actually built in a streamline shape, and sometimes the streamline shape is obtained by enclosing the part in a streamlined case, or by attaching to it a shaped piece of some light material, such as balsa wood. The best faired object is one whose shape approaches that of a tear drop, having a ratio of length to width of approximately 3.5. (F.T.M.)

FALCON. Aves, Falconiformes. Large birds (**Aves**) of prey closely related to the hawks and eagles and like them in appearance. They are found throughout the world.

One species of the Old World is called the windhover, *Falco tinnunculus,* or, in common with other species, kestrel. Another is the merlin, *F. gesalon.* The peregrine falcon, *F. peregrinus,* has been widely used for catching game and other birds.

Several species of falcons and merlins occur in North America, among them the duck hawk, *F. anatum,* pigeon hawk, *F. columbanus,* and the little sparrow hawk, *F. sparverius.* (A.W.L.)

FALCONIFORMES. An order of birds of prey containing the **vultures, falcons, eagles,** and **hawks.** They have strong hooked beaks and, with the exception of the vultures, large curved claws used for grasping prey. The eyes are directed laterally, unlike those of the owls which have similar beaks and claws. (A.W.L.)

FALLFISH. Pisces, Teleostei. A **chub,** *Leucosomus corporalis,* of the eastern states. It lives in lakes and rapid streams and is a food and game fish of moderate worth. (A.W.L.)

FALLOPIAN TUBES (UTERINE TUBES, OVIDUCTS). The two fallopian tubes in the female are situated one on either side of the uterus, extending from its upper angle outward to the side of the pelvis, ending near the right and left ovaries. The end of each tube is surrounded by fringe-like processes called the fimbria. It is partly by means of these processes that the ovum, after discharge into the abdominal cavity, gains access into the tube through which it passes to reach the cavity of the uterus.

It is believed that fertilization by the male sperm cell takes place along the course of the tube.

The fallopian tubes are subject to infection, acute and chronic salpingitis, and abscess formation. They are the most common sites of extra-uterine or ectopic pregnancy. (For a general zoological discussion of this term, see **Reproductive System.**) (D.M.H.)

FALSE BEDDING. **Cross-Bedding.**

FALSE CIRRUS. Cirrus resulting from anvil heads of thunderstorms. (P.E.K.)

FALSE CLEAVAGE. This is also called strain-slip **cleavage** by the British geologists. It differs from the typical slaty cleavage in that it is obviously associated with incipent **foliation** of **metamorphic rocks.** (R.M.F.)

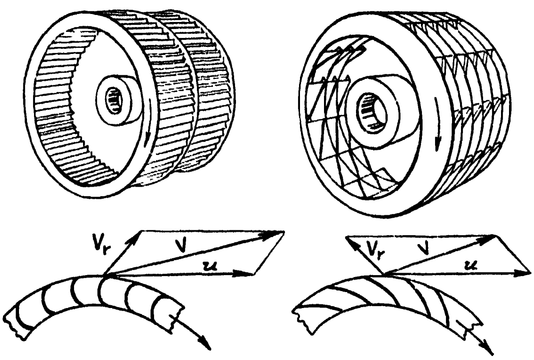
FALSE SCORPION. Pseudoscorpion. **Arachnida.** (A.W.L.)

FAMILY. 1. A group of animals consisting primarily of two parents and their offspring, sometimes with other related individuals. 2. A taxonomic subdivision of an order. In zoology family names are formed of the stem of the type genus with the ending -idae. Thus *Homo,* the genus to which man belongs, has the stem Homin- and forms the family name Hominidae. In botany the ending -aceae is used in a similar manner. (See **Taxonomy** and **Nomenclature.**) (A.W.L.)

FAN, CENTRIFUGAL. Centrifugal action whereby a gas is compressed has been described under the subject **Compressors.** When large volumes are to receive a small compression (pressure rises of 1 lb. per sq. in. or less) the device is called a fan. Centrifugal fans fall in this category and fulfill a variety of needs such as ventilating, heating, combustion draft, and drying service.

In contrast to the high-pressure centrifugal compressor, the fan has narrow blades and very little compression occurring in the blading. However, the blade action on the gas is to increase its speed, thus requiring a diffusion to gain pressure. This diffusion is accomplished in a scroll case surrounding the wheel and comprising the casing of the fan. Diffuser guide vanes may sometimes be inserted in the scroll case to improve efficiency by reducing turbulence. Simple radial blading is sometimes used on account of its cheapness and simplicity, but most fans have blading that is curved. Fig. 1 shows the appearance of wheels incorporating in the one case forwardly, and in the other, backwardly curved blading. Vector diagrams show that for the same relative velocity of the gas leaving the wheel and the same wheel speed, the absolute velocity is greater with forwardly curved blades. Achievement of efficient diffusion is therefore more important with forwardly curved blades

and pressure increase is greater. Conversely for same pressure increase, forwardly curved blading may operate at lower rim speeds. However, backwardly curved



Forwardly curved blades. Backwardly curved blades.
Fig. 1.

blading can be built so that somewhere near the best operating point (maximum efficiency) pressure rise diminishes more rapidly than volume increase and thereby induces a self-limiting feature in power consumption that is desirable in many applications. Power demand continues to increase with discharge in forwardly curved blading until well past the best operating point.

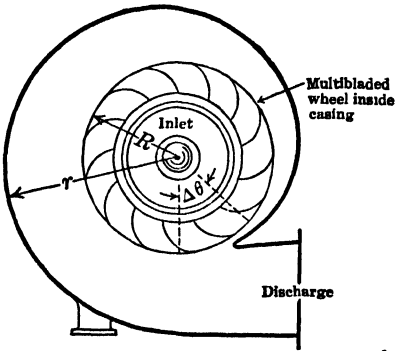


Fig. 2. Centrifugal fan. Typically $r = R\left(1 + \frac{\theta^\circ}{300}\right)$

Since the pressure increments are small, an excellent approximation which simplifies the energy relation is to assume a constant volume flow through the fan. Given the weight of gas flowing per minute, W, and the draft, D (expressed in feet of air), the power imparted to the air is:

$$\text{Air horsepower} = \frac{WD}{33{,}000}.$$

Given the volume delivered per minute, V (in cu. ft.), and dynamic pressure, P (lb. per sq. ft.), power is also:

$$\text{Air horsepower} = \frac{PV}{33{,}000}.$$

The mechanical efficiency of a fan is the ratio of one of the above theoretical powers to the required drive power. Multivane centrifugal fans will usually exhibit an efficiency of from 70% to 80% at their optimum point, with radial plate type fans being somewhat poorer in performance. (F.T.M.)

FAN CHARACTERISTIC. A fan characteristic is a curve showing the relation between pressure and delivery. It is important because a fan operates entirely at the conditions depicted by the characteristic curve. Hence, it is a basis for fan selection. The characteristic is determined by the shape of the blades. Blades curved forward in the direction of rotation have what is known as a rising characteristic—pressure increases with volume delivered. This characteristic is productive of low tip speed but fans having it can overload their drives if ignorantly handled. Backward curved blades have a drooping characteristic.

The centrifugal fan compresses the air or gas but slightly. In modern fan theory the work of compression is neglected and the action is assumed to be similar to a reversed **hydraulic turbine** or a **centrifugal pump.** (F.T.M.)

FAN, DRAFT. The mechanically-driven draft fan is often used to supplement or supersede **chimney** action in the production of **draft.** Without the use of fans it would not be possible to have the compact, high-capacity steam generator or the underfeed stoker. Draft fans are designated as plate (paddle wheel), multivane, or propeller type, the latter being but seldom used for this service. The plate fan is employed to some extent, but the multivane centrifugal fan is the most common type. (See **Fan, Centrifugal.**) Backwardly curved blade wheels are usually selected for forced draft service, because of the high speed, suitable for direct motor drive, the self-limiting power demand (a necessary feature when two or more fans are operated in parallel), and high static efficiency. Induced draft fans handle hot chimney gas. Forwardly curved blades which develop a given draft at lower speeds than those with backward curvature are frequently chosen for this service since the speeds and the centrifugal stresses in the wheels will be least. (F.T.M.)

FAN, PROPELLER. Propeller fans operate with flow of air parallel to the axis of rotation. They may be grouped into (1) fans with thin sheet blades of metal or composition material, and (2) fans with blades of airfoil section. Examples of the first class are the table fans (the common domestic "electric fan"), small ventilating fans, ceiling fans, unit heater fans, and radiator cooling fans. With the exception of certain low-speed ceiling fans, these are characterized by high rotative speed and low efficiency. The blades are often stamped in a single piece from a sheet of metal, then twisted slightly and mounted on the motor shaft. These fans are employed to move air but are not satisfactory if the air is to be forced against any pressure increment. The second class of propeller fans reflects a more scientific application of the axial flow principle. Whereas the first class moves the air largely by impulse against the face of the fan blades, the airfoil sections of the latter class perform in accordance with airfoil theory of lift. While more expensive, they are also more efficient, although the latter advantage is gained in sizes more suitable to industrial than domestic usage. The axial flow fan can move large volumes against light static pressures and is frequently more compact and more readily applied than the centrifugal type. (F.T.M.)

FAN, VENTILATING. Fans in this service are used to move air in predetermined directions for the purpose of changing the air in buildings, removing air charged with offensive odors, furnishing air to tunnels, etc. They are commonly fixed in position and connected to duct systems on the inlet or discharge sides, or both. Propeller fans have a limited use in this field, but ventilating fans are usually centrifugal because the application often requires overcoming of considerable static pressure. (F.T.M.)

FANGLOMERATE. The term proposed by Lawson in 1913 for a conglomerate composed of the coarser **clastic** sediments deposited at the head of **alluvial fans.** (R.M.F.)

FAN-TYPE MARKER. **Radio Range.**

FARAD. **Capacitance; Electric and Magnetic Units.**

FARADAY EFFECT. **Magneto-optical Rotation.**

FARADAY'S LAWS. The well-known Laws of Faraday, in electrochemistry, may be stated briefly as follows: 1. The amount of chemical action is proportional to the amount of electricity which has passed through the **electrolyte.** 2. Ions discharged by the same quantity of electricity are in the proportions of their chemical **equivalents.** (See **Electrochemistry.**) (R.K.S.)

FARSIGHTEDNESS. **Hyperopia.**

FASCIA. Layers of connective tissue composed largely of regularly arranged fibers. They cover muscles. Also marks in the form of bands. (A.W.L.)

FASTENING. **Type of Fastening.**

FAT BODY. 1. A large mass of fatty tissue found in **insects.** It serves for the storage of food during larval life, since it is much smaller in the adult, and is apparently a reservoir for nitrogenous wastes since it contains deposits of **uric acid.** 2. A mass of fatty tissue located near the **gonads** in **Amphibia.** (A.W.L.)

FATHEAD. Pisces, Teleostei. A small **minnow,** *Pimephales promelas,* found throughout the United States in sluggish streams. (A.W.L.)

FATHOMETER. **Sounding.**

FATIGUE. Failure of metal parts by progressive cracking caused by repeated application of stress. Most fatigue failures start at the surface where discontinuities in section such as square shoulders, screw threads, or even tool marks cause a high concentration of stress. Internal discontinuities may also start a fatigue crack, the most notable example being "transverse fissures" in rails which are believed to originate in areas within the rail section known as "flakes," a defect originating during the cooling period after hot rolling. Once a minute crack is started anywhere in the section, the root of the crack becomes the seat of high stress concentration upon subsequent applications of tensile stress, thus the crack will spread until the section is too weak to carry the load and the remaining portion will fracture suddenly. The portion of the section which failed progressively will be worn quite smooth due to the rubbing action of successive stress applications (e.g., alternate tension and compression in a rotating member loaded as a beam), while the suddenly fractured portion will have the usual crystalline appearance which is characteristic of fractures in heat-treated steels. For this or other reasons fatigue failures have wrongly been blamed on "crystallization" of the metal. All metals are crystalline and no alteration in the size or shape of the grains or crystals takes place in service during or before fatigue failure. (Exceptions might be made in the case of lead and other alloys which recrystallize when cold worked at room temperature. See **Recrystallization.**)

The fatigue strength, also called endurance limit, is the maximum stress which can be applied repeatedly without failure. In the case of steel, tests are run at a given maximum stress to 10,000,000 reversals or cycles of stress unless failure occurs earlier. It has been found that failures do not occur in steels after a successful run of this duration (4 days at 1700 rpm or less than 1 day at 10,000 rpm). In the case of aluminum alloys and certain other non-ferrous metals, fatigue failures have occurred after much longer runs, hence tests are sometimes made to 500,000,000 cycles. The materials do not have a true endurance limit and the number of reversals of stress are stated in reporting the fatigue strength.

The most common test is a rotating beam type in which a carefully machined and polished sample is loaded as a beam while rotating in anti-friction bearings. As any point in the periphery rotates from top to bottom to top position the stress changes from maximum compression to maximum tension and back to maximum compression. From 4 to 8 or more individual tests at various maximum stress levels may be required to determine the endurance limit.

The endurance limit for smooth test specimens run in normal atmospheres at room temperature is an ideal or limiting value. In the case of steels not hardened, or heat treated to moderate hardnesses, the smooth specimen endurance limit is approximately one-half of the tensile strength. The endurance limit-tensile strength ratio is less than one-half for many other materials.

The presence of stress raisers, particularly at the surface, will lower the endurance limit. Notch sensitivity can be evaluated as the ratio of the endurance limit of a standardized notched specimen to that of a smooth specimen. Fatigue tests run in a corrosive medium, either gaseous or liquid, generally give much lower endurance limits than tests run in normal atmosphere. Corrosion-fatigue is responsible for many service failures of shafts and other stressed parts of pumps, engines, or processing equipment operating in corrosive media. Protective coatings are sometimes used to improve service life **Nitriding** of alloy steel parts has proved very effective.

In order to guard against fatigue failures in critical parts such as connecting rods, they should be fabricated from high-quality steels using designs that avoid regions of stress concentration such as sharp fillets and engraved part numbers. They should be finished over all, avoiding tool or grinding marks. As a further aid in obtaining high fatigue strength such parts are being surface peened by a shot blasting process which work-hardens the surface and sets up compressive stresses in the surface layers. This raises the endurance limit, apparently by reducing the maximum tensile stresses which can be developed at the surface in normal operation. (R.H.H.)

FATIGUE LIMIT. **Fatigue.**

FATS. **Esters.**

FAUCES. 1. The exposed portion of the cavity of a **snail** shell. 2. The opening of the throat of a **vertebrate,** flanked by the tonsils. (A.W.L.)

FAULT. A fault is a great fracture in the crust of the earth along which movement has taken place with the result that the crustal blocks are displaced relative to one another. This movement is in most cases probably intermittent and the actual individual displacements may be very small, but by accumulation may reach tens, hundreds, or rarely thousands of feet. The fractures themselves may often be traced for many miles. The San Andreas fault, horizontal movement along a portion of which caused the earthquake that so severely damaged San Francisco, California, in 1906, has been traced for about 600 miles.

In describing faults, certain terms have been adopted. Those in most common use are given herewith: the fault plane is the plane of the fracture and may be vertical or at some other angle; the angle between the fault plane and the horizontal is called the angle of dip of the fault plane. The angle between the vertical and the fault plane is spoken of as the angle of hade or

simply as the hade of the fault. The surfaces of the fault plane are called the walls of the fault. If the fault plane dips, the uppermost wall is called the hanging wall, the lower wall the foot wall. These terms are applied irrespective of whether the fault is normal,

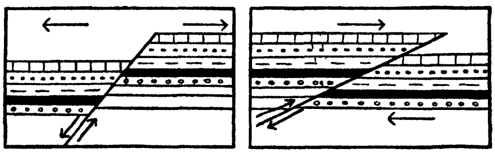

Fig. 1. Structure sections of a simple normal fault (on left) and of a simple thrust fault (on right).

with the hanging wall slipping down the dip of the fault plane, or whether it is a reverse fault with the hanging wall apparently pushed up the dip of the fault plane. A normal fault is sometimes spoken of as a gravity fault. The displacement measured along the fault plane is designated as the slip; the displacement measured vertically is called the throw; the displacement measured at right angles to the plane of the involved stratum is called the stratigraphic throw. The amount of horizontal displacement between the ends of a broken stratum measured at right angles to the direction of strike of the fault plane, is called the heave. The visible evidence of the trace of a fault plane at the earth's surface is called the fault trace. The block of the earth's crust which has moved downward, relatively speaking, to the other is called the downthrown block or referred to as the downthrow side of the fault. The other block is called the upthrown block or the upthrow side of the fault. If the strike of the fault plane is essentially at right angles to that of the **bedding** it is called a dip fault. A strike fault is one in which the

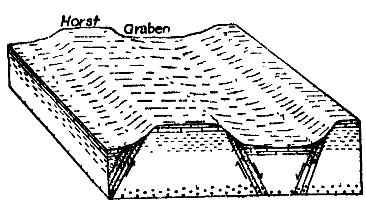

Fig. 2. Block diagram of one type of scenery produced by "normal" or block faulting. It may also be assumed that the graben has been pushed down, and the horst has been pushed up. Neither structure is necessarily entirely the result of tension. Note that the stratigraphic (vertical) order of the formations has not been duplicated or reversed. (*Field, Laboratory Manual, Princeton Univ. Press.*)

movement has been parallel to the strike of the strata involved. A compound fault involving several parallel displacements dipping in the same direction, resulting in a step-like arrangement, is referred to as a step fault. The term graben or trough fault refers to a downthrown area bounded on each side by two or perhaps more faults. A horst is an uplifted area bounded by two or more faults. (E.S.C.S.)

FAULT BRECCIA. **Autoclastic.**

FAULT SCARP. Scarp.

FAUNA. The animal population of a region. (F.T.M.)

FEATHER. The structure characteristic of the vestiture of birds (**Aves**). The development of a feather indicates that it is a modified scale, like those of reptiles and birds.

A feather consists of a central axis or rachis continuous with the hollow quill which is attached to the body. The rachis bears the flat vane of the feather which is made up of many slender barbs bearing barbules along each side. The barbules of adjacent barbs interlock to form the continuous surface of flight feathers and the similar contour feathers of the body. Down feathers are of generally soft structure and lack barbules, and filoplumes are slender feathers with few barbs. (A.W.L.)

FEATHER, AERODYNAMIC SURFACE. **Feathering.**

FEATHER KEY. **Key.**

FEATHER STAR. **Crinoidea.**

FEATHER-BACK. Pisces, Teleostei. A fish (**Pisces**) of peculiar form found in Africa and the Oriental region. (A.W.L.)

FEATHERING. An object of flat plate shape in a fluid stream has maximum resistance to relative motion if its largest area be placed in an attitude perpendicular to the fluid stream, and minimum when the smallest area is so placed. Conditions occasionally arise when it is desirable to have a maximum resistance at one point of a cycle of events, and minimum at another. For example, during the cycle of a rowing stroke, the blade of the oar should have maximum resistance to motion in the water, whereas during the return stroke it should have minimum air resistance. Certain experimental types of lifting planes or **airfoils** have been built involving this same action. The act of first presenting the surface of maximum resistance, followed by the surface of minimum resistance on a return stroke, is known as feathering. In recent years controllable pitch propellers have been equipped with hub mechanisms and controls to permit the pilot to feather the blades when the engine was either throttled or inoperative. This action assists control and performance of multi-engined aircraft having one or more engines inoperative, also allows a single-engined airplane to reach higher terminal diving speeds. Feathering the propeller will keep a damaged engine from "windmilling" and increasing the damage. Feathering is also applied to the change in the angle of setting of the blades of a helicopter either to secure control or to equalize lift on the advancing and retreating sides. (F.T.M.)

FEED. **Cutters, Cam.**

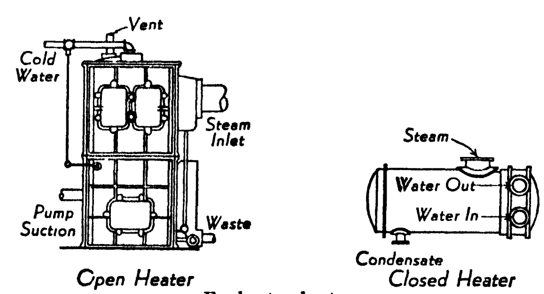
FEED WATER. Feed water is water properly prepared for entering a **boiler** to take the place of that which is evaporated in the generation of steam. Although the instantaneous flow of feed water is not necessarily equal to the rate at which steam is boiled off, the total amount fed over a considerable period of time must equal the evaporation plus such loss as blowdown and steam released through the safety valve. The nearer a boiler design approaches the flash type, the nearer must the instantaneous flow of feed water be to the rate of evaporation. To be suitable for the service, feed water should be at a pressure enough above that of the boiler contents, so that it flows readily into the boiler when the feed valve is opened. It should have chemical purity to the required degree and be heated to a temperature as near that at which the boiler operates as is economically feasible. (F.T.M.)

FEEDBACK. Feedback, or the transfer of energy from a high level point to a low level point, in communications circuits may be either positive or negative. Positive feedback is that in which the signal fed back is in phase with the input signal; thus we might say that some of the output is sent back through the circuit to add to the regular signal present. For **amplifiers** this effect is normally very undesirable, although in some amplifiers it is used to increase the gain. If enough

energy is fed back positively the input can be removed entirely and the signal kept going through the amplifier by the feedback. This is possible since a small signal at the input produces a much larger one at the output and only a small part of this needs to be returned to the input to keep the process going. When this condition is reached the amplifier oscillates or howls. While smaller amounts than this may be used, to increase the gain of an amplifier it is always at the expense of stability and fidelity. An **oscillator** is really an amplifier with a large amount of positive feedback. Negative feedback is that in which the signal fed back to the input is in phase opposition with the input. While this cancels part of the input it has such desirable effects that it is almost universally used for high-grade amplifiers. Negative, or inverse, feedback increases the stability, improves the frequency response, lowers distortion and noise and has other similar desirable results. The improvement along these lines is approximately proportional to the amount of feedback, but a compromise value which will not decrease the gain too much and yet give decided improvement in the other characteristics is used. Since many feedback circuits have phase and amplitude characteristics which vary with frequency an amplifier may have negative feedback at one frequency and positive at another. If the amplifier has sufficient gain in the positive feedback region it will oscillate. If the signal fed back is proportional to the output current it is termed current feedback and stabilizes the current, while if it is proportional to the output voltage it is voltage feedback and stabilizes the voltage. (L.R.Q.)

FEEDER. In electrical circuits this term is used to designate the lines running from a main **switchboard** to branch panels in an installation In radio circuits it is used to designate the transmission line from the **transmitter** to the **antenna.** (L.R.Q.)

FEEDWATER HEATER. The purpose of heating feed water is threefold. First, if the water is heated by heat which would otherwise entirely or partially go to waste, the heating represents a saving of fuel.



Feedwater heater.

Second, the thermal stress induced in the **boiler** plate by contact with a stream of cold feed water is reduced, possibly eliminated. Third, the nearer the feed to saturation temperature the less the heat to be added in the boiler itself and the more the steam-raising capacity of each sq. ft. of heat-transfer surface. This becomes of increasing importance at higher boiler pressures.

Feedwater heaters are divided into two classes, the contact and the surface heaters. Economizer surface and a portion of the boiler surface are actual water heating surface; however, it is customary to refer only to equipment obtaining heat from steam as feedwater heaters.

The open heater is ordinarily built up in rectangular form, but heaters for other than near-atmospheric pressure are constructed in cylindrical form of cast iron or steel plate. The open heater is provided with tiers of trays, properly perforated and inclined to break up the flow of water, delivered by gravity from a distributing trough, into a multitude of small cascading streams which present a large surface to the steam It is possible to heat water to the temperature of saturated steam entering the heater if there are no non-condensable vapors. Heating is by direct conduction from steam to water so the effectiveness as a heater is not adversely affected by scale accumulation. A float-regulated valve admits the cold water required to supplement the returns in drips, condensate, and other uncontrolled feed supply.

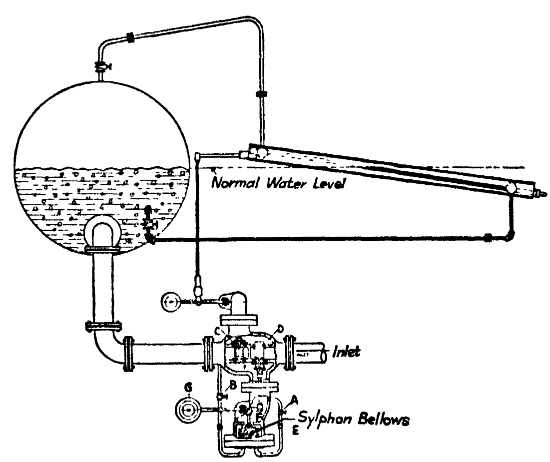
The surface heaters are divided into steam-tube and water-tube types. Most heaters are of the water-tube type. These heaters can also be divided into straight tube and bent tube (U-tubes and steam coils), and into single or multi-pass. The surface heater is used when water is to be heated under pressure without direct contact with the steam. (F.T.M)

FEEDWATER REGULATOR. Air, fuel, and water are the three variables entering into the production of steam "as wanted." The feedwater regulator is the governor of the **feed water** supplied to the boiler.

Soon after steam **boilers** came into use it was discovered that a disastrous explosion resulted if they boiled dry; also that the engine might be wrecked by water passing over with the steam. Naturally great care was taken to prevent the water level in the boiler from passing below or above the safe limits.

Under modern conditions it is necessary for feed water to flow into the boiler almost as rapidly as the steam flows out—and since boilers are approaching the flash type, it is plain that the feedwater regulation should be automatic, purely a machine function. It cannot be done successfully by hand.

There are several types of feedwater regulators, most of them either thermostatically or float operated. In



Feedwater regulator.

order to take advantage of the thermal storage contained in boiler drums between high and low water level, the regulator should gradually increase or decrease the feed on slowly increasing or decreasing steam demands, but it should decrease the feed during rapid increase of steam demand and increase it when the demand decreases rapidly, for in that way the fluctuation of boiler water level can offset the time lag of combustion response to changing steam requirements. (F.T.M.)

FEEDWATER TREATMENT. The purpose of a **feedwater** treatment system is to maintain the surfaces of the **boiler** in the same or approximately the same condition as when new. After entering the boiler, feed water is first heated to the saturation temperature, then evaporated in contact with the hot tube surface.

Unless the concentration of soluble salts and suspended particles in the boiler water is very great the steam will be free of all impurities the feed water might have contained except dissolved gases. The impurities are left behind in the boiler water whose concentration, as a result, increases. The point of evaporation being at the tube surface, there is every opportunity offered the impurities to deposit themselves on these surfaces as a scale. When untreated feed water produces enough scale on the boiler surfaces to interfere with heat transfer, or when it contains elements which either corrode or alter the strength of the boiler metal, feed-water treatment is necessary.

The higher the rate of heat transfer per square foot of surface, the more important it becomes to keep that surface scale-free, because the scale can both reduce the steaming capacity and cause overheating of the tubes. Natural waters usually contain dissolved salts and gases, also some organic and inorganic material in suspension. They rarely are neutral in reaction. The dissolved salts are chiefly the carbonates, sulfates, and chlorides of **calcium, sodium, and magnesium**; and occasionally some **iron, aluminum,** or **silica** salts. **Oxygen** and **carbon dioxide** are the gases. The suspended matter is usually alumina and silica in the form of mud and silt, or, if organic, sewage and industrial wastes.

The troubles caused by the feeding of water of undesirable quality are scaling, corrosion, foaming and priming, and **embrittlement.**

Boiler scale is due, mainly, to the cementing action of salts of calcium and magnesium. Calcium is the worst offender, particularly in the sulfate form. The formation of scale is caused by the dissolved salts in the boiler water reaching a concentration beyond which they are no longer soluble at the boiler temperature. At average boiler temperatures the sodium salts have solubilities running to thousands of grains per gallon. Magnesium sulfate is quite soluble in hot water and the chlorides are sufficiently soluble not to cause scale trouble. But calcium sulfate is less soluble in hot water than in cold. Its solubility varies between 150 grains per gallon in cold water to 5 grains in hot water, which explains why it is so troublesome a substance. Calcium and magnesium carbonates have solubilities so low at 212° F. that water containing them is treated merely by boiling and filtering. The reactions are:

$$Ca(HCO_3)_2 + \text{heat} \rightarrow CaCO_3 + CO_2 + H_2O$$

$$Mg(HCO_3)_2 + \text{heat} \rightarrow MgCO_3 + CO_2 + H_2O.$$

Scaling may take place in boiler drums or tubes, heater tubes, and feedwater piping. Its effect on the piping system is to choke the flow, requiring an increase of pressure to maintain water delivery. Its effect on heat transfer surfaces is to decrease the transfer. Treatment for scale consists of removing the scale-forming elements or replacing them with extremely soluble salts.

Corrosion is the destructive conversion of boiler metal into oxides or iron salts. Corrosion may occur at any place in the feedwater cycle, but it is found principally in boilers, heaters, and piping. It is due either to an acid condition of the water or to dissolved oxygen. From the standpoint of corrosion, scale is a protective agent. The corrosion may be a general loss of metal over the whole tube surface or a localized action. The latter is the more serious as it produces pitting. To prevent corrosion the boiler water is maintained alkaline and, if necessary, the feed water is deaerated to reduce the oxygen content to a suitable value.

Foaming refers to that condition of boiler operation where a stable foam is produced. It may or may not be accompanied by priming, which is the production of wet steam or, in the aggravated case, slugs of water. Priming can be produced by other causes than foaming, for instance, carrying too high a water level, insufficient disengagement area, or a pulsating steam demand that overtaxes the boiler steam storage. Foaming results also from saponification of the boiler water through mixture of oil or grease with the alkali. Floating organic matter is another source of foam. When foaming is due to concentration of salts in the water the condition is relieved by altering the treatment or by blowing down more of the concentrated water.

Chemical treatment is classed as external or internal, depending on whether the reactions are completed before the water enters the boiler or in the boiler. Internal treatment, if scientifically designed and controlled, is an effective method and is the best system where the proper treatment for the boiler might prove injurious to the steel tube economizers.

External water softeners are of two types, precipitation and base exchange. A precipitation softener embodies the principle of using calculated quantities of soluble reagents to react with the hardness in the raw water. Two treating tanks are used in the intermittent system, one supplying treated water to feed service, while the other is receiving its charge of chemicals and water or maintaining a quiescent condition so that the precipitate may settle out. Water flows continuously from inlet to outlet in the continuous type of softener. Reagents are added at the inlet and what precipitate does not settle out in the reaction tank is removed by filtration.

A base exchange softener removes the hardness by a simple filtration of the water through a bed of active material which exchanges its sodium base for the magnesium and calcium in the water. Natural and artificial **zeolites** are used as the active material. Natural zeolite is hard and dense; artificially prepared silicates such as permutit ($Na_2(Al_2Si_2O_8)$) are porous, thereby exposing a much greater surface to react with the water. (F.T.M.)

FEHLING'S SOLUTION. This is an alkaline solution of **copper** hydroxide and sodium or potassium **tartrate** in sodium hydroxide used either as a mild oxidizing agent or as a test for easily oxidizable groups such as **aldehyde** groups. The formation of cuprous oxide is a positive test, its color red but often yellow at first. (See **Carbohydrates.**) (R.K.S.)

FELDSPAR. Feldspar is the name of a group which includes the most important of the rock-forming minerals, making up perhaps as much as 60% of the earth's crust.

This group of minerals consists of three **silicates:** a **potassim-aluminum silicate**, a **sodium**-aluminum silicate, and a **calcium**-aluminum silicate ($KAlSi_3O_8$, $NaAlSi_3O_8$, and $CaAl_2Si_2O_8$) and their **isomorphous** mixtures.

The various members of the feldspar group show many characteristics in common. Crystallizing in the **monoclinic** and triclinic systems, they show similarity of crystal habit, cleavage and other physical properties as well as similar chemical relationships.

Orthoclase, $KAlSi_3O_8$, derives its name from the Greek words meaning right or straight, and fracture, because its two cleavages are at right angles to each other. It crystallizes in the monoclinic system and its crystals are usually prismatic; it occurs also in coarsely cleavable masses. Hardness, 6; specific gravity, 2.56–2.58; luster, vitreous to pearly; colorless to white, gray, yellow or red, rarely green. Twin crystals not uncommon.

Orthoclase is a common constituent of many igneous rocks and is often found in huge masses in pegmatite veins. Localities for orthoclase are so numerous as to prohibit a complete list. Adularia (from Adular) is essentially a pure potassium silicate; when pearly and opalescent it is called moonstone and frequently used for jewelry. These opalescent varieties are known to be an intergrowth of orthoclase and albite. A glassy kind of orthoclase, sanidine, is found in the trachytes of the Drachenfels, Germany. Beautiful moonstones come

from Ceylon and Switzerland, in the United States from California and Virginia.

Orthoclase is found in the New England **pegmatites**, in New York, Pennsylvania, Virginia, North Carolina, Arkansas, Texas, Colorado, California and elsewhere. Its commercial use is in the manufacture of porcelain and as a constituent in scouring powders.

Microcline, $KAlSi_3O_8$, is chemically the same as orthoclase, but belongs to the **triclinic** system, the prism angle being slightly less than a right angle (89° 30′), hence the name microcline from the Greek meaning small, and to slope. Microcline is like orthoclase in all physical properties and can be distinguished from it surely only by optical examination. Under the polarizing microscope microcline displays a minute multiple twinning which results in a grating-like structure that is unmistakable. It is probable that much orthoclase would, upon proper examination, prove to be microcline. Amazon stone or amazonite is a beautiful green microcline occurring in the Ilmen Mountains in the Urals, Italy, Norway, Madagascar, and in the United States in the Pikes Peak region, Colorado, Virginia, North Carolina and sparingly in the pegmatites of New England.

The name amazon stone is derived from the application of this term to some green mineral found by the Spaniards among the aborigines of the Amazon Valley in South America. As no microcline is known to occur in the region there must have been some confusion with another green-colored substance.

A soda microcline, anorthoclase, is known, which is probably an isomorphous mixture of $KAlSi_3O_8$ and $NaAlSi_3O_8$, the sodium-aluminum silicate being in the greater proportion. The soda feldspar albite, $NaAlSi_3O_8$ and the calcium feldspar anorthite, $CaAl_2Si_2O_8$ form an isomorphous series from pure albite at one end to pure anorthite at the other, the two molecules appearing to be completely miscible one with the other. The members of this series are spoken of as the soda-lime (or lime-soda) feldspars, and as a group are called the plagioclase feldspars from the Greek meaning *oblique* and *fracture*, referring to the two cleavages at an angle that differs slightly from a right angle. Nearly always present are the striations, fine parallel lines, resulting from minute multiple **twinning**, which, never seen on orthoclase or microcline, are therefore an important diagnostic feature.

More or less arbitrarily, four intermediate **plagioclase** feldspars are recognized between albite and anorthite; these are listed below together with the approximate percentage of each molecule present.

	% of $NaAlSi_3O_8$	% of $CaAl_2Si_2O_8$
Albite	100 to 90	0 to 10
Oligoclase	90 to 70	10 to 30
Andesine	70 to 50	30 to 50
Labradorite	50 to 30	50 to 70
Bytownite	30 to 10	70 to 90
Anorthite	10 to 0	90 to 100

Albite is so called from the Latin, *albus*, in reference to its usual pure white color. It is a sodium aluminum silicate corresponding to the formula $NaAlSi_3O_8$. It crystallizes in the triclinic system commonly in tabular crystals. Twinning is very common, thin twinning lamellae producing a series of fine striations on certain crystal faces. There are two good cleavages at an angle of 86° 24′ to each other. Hardness, 6; specific gravity, 2.62; luster, vitreous to pearly. It may be colorless to white or gray and transparent to opaque.

Albite is a relatively common and important rock-making mineral associated with the more acid rock types and in **pegmatite** dikes, often with rarer minerals like **tourmaline and beryl.** There are many famous localities in Europe in the Swiss and Austrian Alps, the Urals, the Harz Mountains, in Italy, France and Norway. Brazil has yielded fine specimens. In the United States notable localities are Paris and Auburn, Maine; Chesterfield, Mass.; Haddam, Conn.; Amelia County, Va.; and the Pikes Peak region of Colorado. It is used in the ceramic industries and also in the manufacture of artificial teeth.

Anorthite was named by Rose in 1823 from the Greek meaning oblique, referring to its triclinic crystallization. The physical properties are essentially the same as for albite, except that the specific gravity of anorthite is somewhat greater, 2.74–2.76. Anorthite is characteristic of the basic igneous rocks such as gabbro and basalt. Anorthite is found in the lavas of Vesuvius and Monte Somma, Italy; in Finland, Japan, and in Sussex County, N. J.

The intermediate members of the plagioclase group are all very similar and with the exception of certain labradorites, cannot be distinguished from each other ordinarily save by optical means. Oligoclase is a common mineral in such rocks as **granites, syenites, diorites,** their extrusive equivalents and many **gneisses.** It is a frequent associate of orthoclase. The word oligoclase is derived from the Greek meaning little, and fracture, in reference to the fact that its cleavage angle differs slightly from 90°. Sunstone is mainly oligoclase (sometimes albite) spangled with flakes of hematite.

Andesine is a characteristic mineral of rocks such as diorites which contain a moderate amount of silica and related extrusives, such as andesites. Because of its occurrence in these latter andesine derives its name from them as well as from the Andes Mountains.

Labradorite is the characteristic feldspar of the more **basic** rock types like diorite, **gabbro, andesite** or **basalt** and it is usually associated with some one of the **pyroxenes** or **amphiboles.** Labradorite frequently shows a beautiful play of iridescent colors due to minute inclusions of another mineral. The classic locality for this mineral is of course Labrador, whence its name. It is a constituent there of the rock **anorthosite** and is found in the anorthosites of the Provinces of Quebec and Ontario and in the Adirondack region in New York State.

Bytownite, named from Bytown the former name for Ottawa, Canada, is a rare mineral occasionally found in the more basic rocks.

The feldspars crystallize from the **magma** in both extrusive and intrusive rocks; they occur as contact minerals, in veins and are developed in many sorts of **metamorphic** rocks, e.g., albite **schists.** They may also be found as mechanical deposits in various sedimentary rocks. (E.S.C.S.)

FELSITE. Felsites are defined by American geologists as dense, fine-grained, light-colored rocks rich in silica, hence classified with the **rhyolites,** from which some of them have been formed by **devitrification.** Felsites may occur as intrusive dikes but in general are found as **extrusive** rocks. They frequently occur interbedded with volcanic ash, tuff or breccia. According to American usage any light-colored lava whose ground mass or matrix is so fine-grained that the individual minerals cannot be distinguished by the naked eye (macroscopically) may be roughly classified as felsite, hence the prevalence of the term felsitic texture. When felsites show **phenocrysts** they are called felsite porphyries. The term felsite was first applied by Gerhard in 1814 to the fine ground mass (matrix) of **porphyries,** and is therefore one of the oldest, commonly used, petrological terms. (R.M.F.)

FEMALE. **Sex.**

FEMIC. This term is used by petrologists to designate the more common ferromagnesian (see **Iron; Magnesium**) minerals such as **pyroxene** and **olivine.**

Rocks which are relatively rich in femic minerals are said to be urafic. (R.M.F.)

FENCE. **Woodworking.**

FENNEC. Mammalia, Carnivora. Animals of two species which resemble foxes with enormous ears. One, *Vulpes zerda*, occurs in northern Africa, and the other, *V. famelicus*, in Syria and adjacent regions. (A.W.L.)

FENNEL. **Carrot Family.**

FERBERITE. **Wolframite.**

FER-DE-LANCE. Reptilia, Sauria. A large poisonous **snake**, *Lachesis lanceolatus*, of tropical America. It reaches a length of 7′ and is active at night. A **pit viper.** (A.W.L.)

FERGUSONITE. A mineral multiple oxide containing columbrium, tantalum and titanium. Essentially an oxide, or columtate-tantalate of yttrium. Crystallizes in the tetragonal system. Hardness, 5.5–6.5; specific gravity, 5.6–5.8; color, variable. Named after Robert Ferguson (1799–1865), Scotland. (R.M.F.)

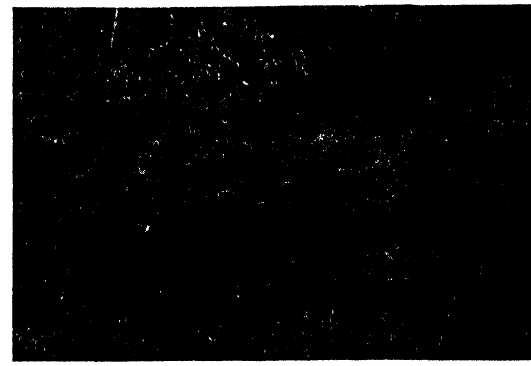
FERMAT'S PRINCIPLE. This is a law of optics recognized nearly 300 years ago by Fermat. It states that when light proceeds by any path from a point A to another point B, the time required in its passage is either a minimum or a maximum as compared to other, arbitrarily chosen, adjacent paths. If the light is reflected from A to B by a plane surface, or is refracted at a plane surface on its way from A to B, the time is a minimum. For a curved reflecting surface, the time is a minimum if the surface has less curvature than the "aplanatic" surface osculating with it at the same point (i e., the surface which gives rise to no **spherical aberration**); and this holds true also for a curved refracting surface. In these cases the law is known as the "principle of least time." But if the reflecting or refracting surface has greater curvature than the aplanatic surface at the same point, the time for the actual path is a maximum; that is, if the light could be made to follow a path through any other point of the curved surface than the one it actually passes through, it would do so in less time. For all points on a given aplanatic surface, the time is the same, and the light, if unobstructed, actually does follow paths through all of them. (L.D.W.)

FERMENTATION. While in recent literature there has been a tendency to extend the use of this term to include many **biochemical** reactions catalyzed by enzymes, this term applies strictly to the chemical conversion of **glucose** into **ethyl alcohol** under the influence of the enzyme **zymase.** (See **Carbohydrates.**) (R.K.S.)

FERNS. Pteridophytes. The ferns and their allies form the third division of the plant kingdom. This is a small division comprising only about 4500 species of plants, few of which are very large. But in past times, and especially in the **Carboniferous** period, plants of this division were more numerous and many of them of very large size.

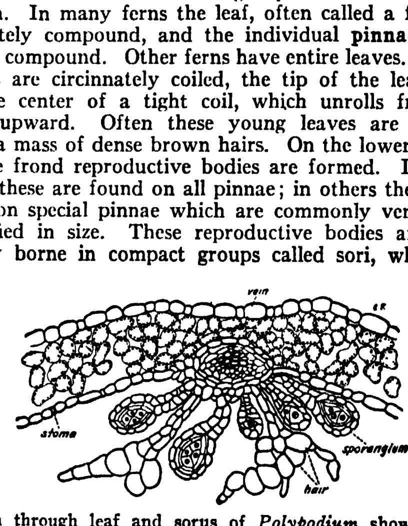
At the present time the ferns are found in nearly all parts of the world, especially in regions where there is plenty of moisture. They are particularly numerous in the tropics. There also the largest of the ferns, called tree ferns, are found. These tree ferns have an erect usually unbranched trunk bearing at its top a crown of much dissected leaves of large size. Tree ferns are from 10–30′ in height; a few may reach a height of 50′.

In nearly all ferns the stem is a slender structure. In many species it grows underground as a creeping horizontal **rhizome**; in other species it is shorter and erect, but seldom rises much above the surface of the ground. From the stem numerous fine wiry roots extend into



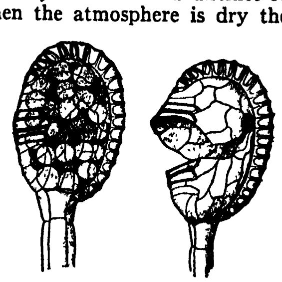
Tree ferns in African forest. (*American Museum of Natural History.*)

the ground. The leaves of ferns having creeping rhizomes are borne singly at the nodes; those of erect-stemmed ferns are borne in a group which forms a close crown. In many ferns the leaf, often called a frond, is pinnately compound, and the individual **pinnae** themselves compound. Other ferns have entire leaves. Young leaves are circinnately coiled, the tip of the leaf being in the center of a tight coil, which unrolls from the base upward. Often these young leaves are covered with a mass of dense brown hairs. On the lower surface of the frond reproductive bodies are formed. In many ferns these are found on all pinnae; in others they occur only on special pinnae which are commonly very much modified in size. These reproductive bodies are commonly borne in compact groups called sori, which are



Section through leaf and sorus of *Polypodium* showing sporangia in various stages of development.

often covered by a protective structure, the **indusium.** The reproductive bodies are stalked sporangia containing **spores**, which are freed by the action of certain special cells of the **sporangium.** These cells have thick inner walls and in many ferns form a distinct row called the annulus. When the atmosphere is dry the cells of the



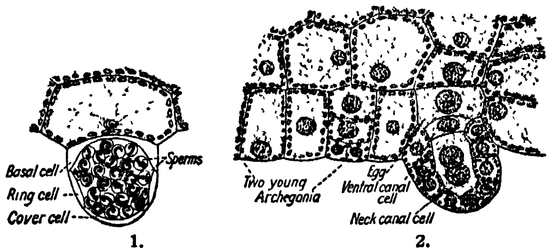
1. 2.

Fern sporangia. 1, Unopened sporangium filled with spores; 2, The empty sporangium after the annulus has returned to its first position.

annulus of a mature sporangium lose water and gradually contract. As a result, a considerable strain is exerted by the thin outer wall of these cells, so that

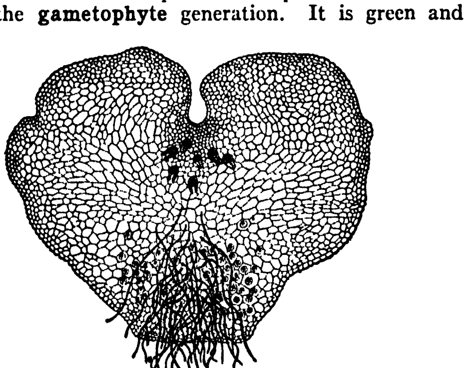
the annulus is pulled backwards, a break occurring in a group of thin-walled cells known as the **stomium.** Finally the tension becomes too great and the annulus snaps back violently, catapulting the spores out of the sporangium.

These spores, carried by air currents to a region where moisture is sufficient, germinate. They do not, however, form a new fern plant. Instead they develop a small delicate green plant called the prothallium. In many ferns this is a heart-shaped body one cell thick. In others it is a branched object resembling certain species of algae, and in still other ferns it is a small tuberous body. From the lower surface of the prothallus numerous short **rhizoids** grow down and anchor it firmly in the substratum. On the lower surface also, reproductive bodies are formed. These consist of two kinds, commonly found on the same prothallus. One, usually in the basal portion of the prothallus, is the **antheridium.** An antheridium is a small multicellular organ in which are formed many small sperms. Fern sperms are spirally coiled cells, each having a group of cilia at the tip.



1, Mature antheridium of fern. 2, Two young archegonia of fern and one mature one. (*From Chamberlain's Elements of Plant Science, McGraw-Hill Co., Inc.*)

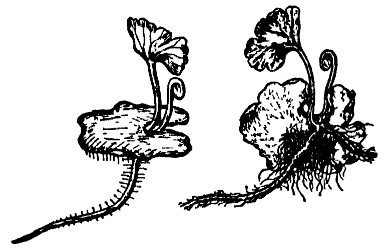
The female sex organ is the **archegonium.** These are commonly found near the notch of the prothallus. Each archegonium is a small organ consisting of a basal layer of cells surrounding the single large egg cell and a short tube surrounding a row of cells known as the neck cells. These break down, forming the neck canal, through which the sperm swim to unite with the egg. The fertilized egg or **zygote** immediately starts dividing and gives rise to a new fern plant. The prothallium of the fern is the **gametophyte** generation. It is green and



Fern prothallium. View of the under side showing archegonia near the apical notch and antheridia among the rhizoids near the base. (*From Sinnott's Principles and Problems, McGraw-Hill Co., Inc.*)

very much smaller than the sporophyte, of which it is entirely independent. Water is absolutely necessary for the prothallium to give rise to a new sporophyte.

The ferns are of very little importance to man. One species, the Christmas fern, *Polystichum acrostichoides,* has thick evergreen leaves which are often used for decorative purposes. This fern grows wild in open woods of the north temperate region. Another fern, the maidenhair, *Adiantum pedatum,* and related species, is frequently grown as a decorative plant because of its delicate fronds. However, the fronds wilt too quickly to be of much use if cut from the plant. Species of



Fern embryo sporophyte still attached to its parent (the gametophyte) but differentiated into its parts and making its own food. Left, as seen from above; right, seen from below.

Osmunda, including the Cinnamon fern, the interrupted fern, and the royal fern, are often planted in shady places for ornament. From these ferns is obtained a

A single fern microgamete, killed and stained so that the parts of the cell are visible. (*After Steil.*)

coarse fiber used as a potting substance on which to grow epiphytic orchids.

Sometimes planted as a curiosity, *Camptosorus rhizophyllus,* the walking fern, gets its name because the tips of the fronds bend down to the ground and take root. New plants are formed at these points. This is a special

Plants of the walking fern, *Camptosorus rhizophyllus.*

form of vegetative reproduction. Several ferns propagate themselves by forming small bulbils on the surface of the fronds. Eventually these drop off and take root, giving rise to new plants. *Cystopteris bulbifera* is a fern propagating in this way. One of the commonest and best known ferns is the common **brake,** *Pteris aquilina,* which grows on dry hillsides and in open woods.

The Pteridophytes include not only the ferns or Filicales, but also the **Horsetails, Club-Mosses,** and the

Quillworts. These three groups are called the fern allies. (See also **Paleobotany.**) (R.M.W.)

FERRATES. Iron.

FERRET. Mammalia, Carnivora. 1. A plains species which preys chiefly on prairie dogs. Found from western Dakota to Montana and Texas. The black-footed ferret, *Mustela nigripes*. 2. The domestic ferret, a descendant of the European polecat, used to catch rats and mice and sometimes to pursue other animals into their burrows. (A.W.L.)

FERRET-BADGER. Mammalia, Carnivora. Animals of several species found in the forests of the Oriental region. They are intermediate in form between the slender carnivores of which the ferret is an example and the more stocky badgers. (A.W.L.)

FERRIC. Iron.

FERRITE. Iron; Steel.

FERROALLOYS. Most alloy additions to **cast iron** and **steel** are made by adding ferroalloys to the molten metal in the melting furnace or ladle. Ferroalloys have high contents of manganese, silicon, chromium, molybdenum, etc., with the balance principally iron. A standard grade of ferromanganese, for example, has 78–82% manganese, 15–19% iron, 6–8% carbon, under 1% silicon, under 0.35% phosphorus, and under 0.05% sulfur. In addition to the alloy content, the impurities or residual elements determine the grade and cost. A low carbon content is often desirable so that the alloy addition may be made without increasing the carbon content unduly.

Certain alloys are added to steel as pure metals rather than ferroalloys.. Included among these are nickel, copper, aluminum, and cobalt. (R.H.H.)

FERROMAGNETISM. Magnetism.

FERROUS. Iron.

FERRUM. Iron.

FERTILIZATION. The union of reproductive cells of the two sexes to form a new individual.

In many species of animals germ cells of the male are transferred to the genital passages of the female in the process of **insemination** prior to fertilization, and in others both sexes discharge their **germ cells** into the water. In either case the **spermatozoa** swim about in the liquid surrounding them until they meet the ova.

When a spermatozoon meets an **ovum** either the entire male cell penetrates the surface and lodges in the cytoplasm of the egg or the tail alone is left outside. After entering, the head rotates so that the basal part is toward the interior of the ovum. At this point a mitotic figure develops. The nuclei of both eggs and sperm may enter the resting state as male and female pronuclei prior to their union. Whether this step occurs or not, the **chromosomes** derived from the two nuclei enter the mitotic figure and the first **cleavage** division results. Since each germ **cell** has only one chromosome of a kind as a result of **meiosis**, the diploid number characteristic of the species is restored by this union.

The ovum reacts to the entry of the sperm head with peripheral changes which prevent the entrance of other male cells. A fertilization membrane separates from the surface of the egg and in some species a redistribution of cytoplasmic materials takes place.

Although some eggs develop normally without fertilization (**parthenogenesis**) and others may be stimulated artificially to do so, fertilization is the normal cause of development in most species. It is also important for the combination of hereditary qualities (see **Heredity**) of two individuals. (A.W.L.)

FERTILIZERS. In connection with the effective use of soils and the economic yield of crops, it is requisite that the exhaustion of soils by the removal of chemical elements of the crops be compensated by the addition of such elements as may not be spontaneously supplied by the soil. It has been found that the primary needs in this respect may be met by the addition of so-called fertilizers containing one or more of the three elements, **nitrogen, phosphorus, potassium.** Secondary needs require in some cases **sulfur, calcium.** Examination of a tabulated report of the constituents of the ashes of certain kinds of crops helps to make these points clear. Nitrogen does not appear in the ash, but must be supplied from the soil. **Silicon, magnesium, iron, chloride** are usually available in sufficient amounts. The constituents of plant ash vary with the kind of crops, and the weight of a given crop varies with the soil and its physical and chemical treatment, and with the season.

The content of each of the three chemical fertilizer elements is usually expressed in a characteristic manner, thus, for illustration, "4–8–2," which signifies that the percentage composition of the dry fertilizer is 4% **nitrogen** (N) element, 8% **phosphorus** pentoxide (P_2O_5), spoken of as "phosphoric acid," and 2% **potash** (K_2O). This expresses the composition of a "mixed" fertilizer, and on the same basis of expression "sulfate of ammonia" ($(NH_4)_2SO_4$) would be "21–0–0," "nitrate of soda" ($NaNO_3$) "16–0–0," "superphosphate of lime" ($Ca(H_2PO_4)_2 \cdot CaSO_4$) "0–35–0," "sulfate of potash" (K_2SO_4) "0–0–54," "muriate of potash" (KCl) "0–0–63."

CONSTITUENTS OF ASH OF NORMAL CROPS

Common nitrogen fertilizers are **ammonium** sulfate, **sodium** nitrate, calcium **cyanamide**, organic substances, such as packing house recovered wastes, tankage, fish scrap, cotton seed meal, treated garbage and sewage, manure; **phosphorus** fertilizers are **calcium** dihydrogen phosphate, either as "superphosphate" or "treble superphosphate," **calcium** phosphate of "phosphate rock" or of bones; **potassium** fertilizers are potassium chloride or sulfate. Sulfur is supplied in three of the above, namely, ammonium sulfate, "superphosphate" and "sulfate of potash," or may be used as gypsum or sulfur; calcium is also supplied in "superphosphate" and "treble superphosphate," or may be used as gypsum or limestone.

The following are typical analyses of phosphate rocks and bones:

In making superphosphate about equal weights of Florida phosphate rock and sulfuric acid are used. (R.K.S.)

FEVER. This term is used to describe elevation of the body temperature over the normal 37° C. or 98.6° F. Fever occurs most commonly in infections, but may accompany a variety of other diseases. The type of fever is often characteristic for the disease, and is described according to the constancy with which the elevated temperature is maintained. Thus, a continuous fever is one that is maintained at a fairly constant level for several days. When there are moderate fluctuations, the temperature is said to be remittent. If the temperature approaches or reaches normal during some part of the day but rises considerably at other times, the fever is said to be intermittent. Rises in temperature may be gradual, or very sudden following chilly sensations or shaking chills. Fever may terminate slowly by lysis or suddenly by crisis.

Conditions other than infections associated with fever are reactions to injections of foreign protein or certain chemical substances, excessive loss of water from the body, and hemorrhage or tumor in the region of the brain where the heat-regulating centers are located. Malignant tumors anywhere in the body, **leukemia,** cirrhosis of the liver, and other systemic diseases are frequently accompanied by fever.

The question is often debated as to whether fever is beneficial during an infectious disease, or should attempts be made to reduce it. Since its mode of production is not clearly understood, there is no ready answer. In general, fever of moderately high degree may be regarded as beneficial since it is known that at higher temperatures the body finds it easier to produce protective antibodies to fight infection. Furthermore, the increased temperature is harmful to micro-organisms, making it more difficult for them to grow and increase within the body. Excessively high fevers such as occur in sunstroke demand active measures toward their reduction; they indicate that the heat centers of the brain are probably temporarily overwhelmed and unable to cope with the emergency. (D.M.H.)

FEVER BLISTERS. **Herpes Simplex.**

FIARD. **Fiord.**

FIBERS. Stem. Fibers are long, usually slender, thick-walled **sclerenchyma** cells. Usually they have pointed ends and lignified (**lignin**) walls. In most cases the central cavity of the fiber, the lumen, is very small, due to the thickness of the wall. Fibers are found in many parts of a plant, but are most frequent in the cortex and in the vascular cylinder. The name bast fibers is often given to fibers occurring in the pericycle, **cortex,** and in the **phloem** region. Plant anatomists prefer to designate all fibers according to the tissue to which they belong; xylem fibers, phloem fibers, pericyclic fibers and cortical fibers. Fibers may occur as single cells or in compact groups forming extensive masses, giving to the part of the plant in which they occur considerable tensile strength. Masses of fibers of this sort give us **flax, hemp, jute,** and **ramie.** Jute is composed of fibers of the secondary phloem (inner bark). Flax, hemp, and ramie fibers are developed in the pericycle.

The single-celled outgrowths which surround the seeds of the **cotton**-plant are often called fibers. They are slender hollow cells of almost pure **cellulose,** and strictly are epidermal hairs, as are also the cells of **kapok.** (R.M.W., B.S.M.)

FIBRIL. A minute thread-like structure in a **cell,** also the smaller components of the intercellular white fibers of connective tissue.

Fibrils occur near the surface of smooth muscle cells and connective tissue cells (border or myoglia fibrils and fibroglia fibrils respectively) and in fully differentiated muscle and nerve cells (myofibrils and neurofibrils respectively). (A.W.L.)

FIBROID TUMOR. A benign **tumor** of fibrous or connective tissue. Fibroid tumors may occur in various parts of the body but are most often found in the uterus, where they may grow to great size, produce pressure symptoms, and abnormal bleeding. Uterine fibroids are the most common cause for removal of the uterus (**hysterectomy**). (R.S.M.)

FIBROLITE. **Sillimanite.**

FICTITIOUS MEMBER. **Graphical Statics.**

FIDELITY. This is usually applied to an **amplifier** or communications circuit to indicate its ability to reproduce the original signal without **distortion.** A high-fidelity audio amplifier will amplify all audio frequencies equally while a poor-quality amplifier will badly attenuate certain frequencies, usually the low and high frequencies while passing the middle audio range. Many radio **receivers** have fidelity controls. These are in the **intermediate frequency** circuits and have the effect of broadening the pass band of such circuits. Most of the loss of the high frequencies in the radio is due to the various selective circuits cutting out the higher **sideband** frequencies, and, since these represent the higher audio frequencies, the highs are missing in the output. The use of fidelity controls allows the selective circuits to be broadened for receiving high-fidelity local programs where there is not likely to be adjacent station interference, yet allow the circuits to be returned to the selective condition for tuning in weaker stations which cannot override interference. (L.R.Q.)

FIELD. In electric **motors** and **generators** the field is the part of the machine which furnishes the magnetic flux which reacts with the armature to produce the

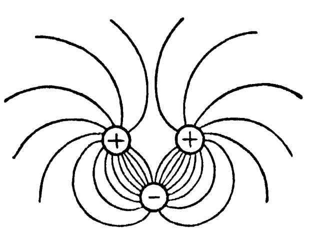
desired machine action. In d-c machines the field may be shunt, i.e., connected in parallel with the armature, or series, i.e., connected in series with the armature. A given machine may have both types of fields, in which case it is a compound machine. For synchronous motors and generators the field is separately excited from a d-c source and is usually the rotating part of the machine. Field is also used in the sense of a magnetic field set up around a conductor or coil, or an electrostatic field between conductors at different potentials. These fields are represented by lines of magnetic or electrostatic flux. The term is also used to denote the energy radiated from an **antenna** system of a radio **transmitter.** This field is an electromagnetic type field consisting of both an electrostatic and a magnetic component. It is the cutting of the receiving antenna or circuit by one or both of these component fields which causes the signal voltage to be induced in the antenna and hence introduced into the main receiver circuit. (L.R.Q.)

FIELD INTENSITY. This is a measure of the strength of the magnetic or electric field at any point. In radio the field intensity at the receiving **antenna** determines the signal which will be induced in the antenna and hence is an important consideration in the design of the **transmitter.** By proper choice of the power and frequency of the transmitter and type of transmitting antenna considerable control may be exercised over the field intensity at the receiving point. (L.R.Q.)

FIELD SPLICE. Splice.

FIELDFARE. Aves, Passeriformes. A common **thrush,** *Turdus pilaris,* of northern Europe. (A.W.L.)

FIELDS OF FORCE. A field of force is commonly recognized by the fact that an appropriate test object placed therein gives evidence of a force acting upon it. Thus a stone in the earth's gravity field has weight, a charged pith ball near an electrified glass rod is urged toward or away from the rod, etc. The concept of such regions of space in which there is a condition of stress analogous to elastic tension or compression is due primarily to Michael Faraday. He initiated the "field theory" as a substitute for the older "action-at-a-distance" concept, and explained the observed behavior of appropriate objects in the neighborhood of magnets, electric charges, or gravitating masses as due to stresses along definite stress lines or "lines of force." Every student of physics is familiar with the experiment of



Typical electric field between charged conductors, mapped by lines of force.

mapping a **magnetic field** by means of iron filings sprinkled upon a card placed over a magnet. In this experiment, attention is first called to the direction of the lines as indicating the direction of the magnetic stress; later the student learns to interpret the closeness with which the lines are packed as corresponding to the intensity of the field. The lines are, of course, pure conventions; but they are nevertheless useful both qualitatively and quantitatively in discussions of field theory. Analogous concepts are applied in the case of electric and gravitational fields, and are useful in the theory of the **electromagnetic field,** so ably developed by Maxwell. In recent years Einstein has undertaken to identify these different fields of force as components or aspects of a more general entity, and has developed his unified field theory as a feature of general **relativity.** (L.D.W.)

FIG. *Ficus carica.* Moraceae. Figs are the fruit of a shrub or small tree probably native to southwestern Asia. They have been cultivated since earliest recorded times, being widely used by the Hebrews, greatly improved by the Greeks, and highly valued by the Romans. The fig tree is now grown in cultivation in nearly all tropical countries and many subtropical regions; in the United States it is grown to some extent in the southwestern states, notably in California.

The plants have alternate leaves which are rather thick and rough surfaced above, but soft-hairy beneath. The leaves are deeply lobed in the cultivated varieties. The minute flowers are borne on the inside of the hollow receptacle, which develops into a pear-shaped body with a minute opening at its apex. The fruit developing from this is a synconium, composed of many small fruits inserted in the inner wall of a hollow fleshy receptacle. The narrow passage into this is partly closed by numerous small **bracts.**

There are four kinds of flowers in the fig. Staminate flowers, each having four pollen-bearing **stamens,** occur in the wild "caprifig." A few cultivated forms have staminate flowers. **Pollination** is brought about by using pollen from caprifigs, and is called caprification. Pistillate flowers, each having a single **pistil** which if pollinated produces a seed. These flowers are short-stalked. The third flower type is the gall-flower, so-called because a small wasp, *Blastophaga grossorum,* lays its eggs in them. The developing **larvae** causes the **ovaries** to become swollen **galls,** incapable of developing seeds. This type of flower occurs only in caprifigs, in the basal portion of the synconium. Lastly, in varieties of cultivated figs there are found sterile flowers, which will neither produce seeds nor become galls; these are called mule flowers. Caprifigs contain the first three types of flowers. If pollen is needed to insure fruit development, caprifigs must be planted, since they alone have pollen-bearing flowers. So among Smyrna fig trees, the fruits of which fail to develop unless pollinated, caprifigs must be planted.

In Mediterranean countries, where figs are grown in abundance, three crops are produced each year. The first fruits, known as profichi, are formed in the spring. In the pistillate flowers of these the female wasp lays her eggs, so that galls are formed in the profichi. When the young wasps emerge, these profichi are gathered and hung among Smyrna figs. Wasps escaping have to crawl past the staminate flowers near the aperture of the synconium and so are dusted with pollen. The wasp then enters and pollinates a flower of the second crop, thus insuring fruit development. This second crop is known as mammoni. The third crop, the mammae, remain on the trees. It is in these that the wasp passes the winter.

Fig fruits are gathered and sometimes eaten fresh, but more frequently dried in the sun, then pressed together and shipped. Smyrna figs are often enlarged by pulling during drying. The fruits produce a mild **laxative** effect, and so are sometimes prescribed in cases of chronic constipation. From them a wine is sometimes made, and alcohol produced. The wood of the fig tree is occasionally used in cabinet work.

Propagation is usually by stem cuttings, but sometimes by budding or **grafting.**

Other species of *Ficus* are of some importance. In southern Asia the Sacred Fig, also called Peepul or Bo-tree, occurs. This is a large tree with deltoid leaves, the apex of each leaf tapering into a long point. Any water falling during a tropical rain runs off rapidly from this

point, so that the leaf surface does not long remain wet. The tree is held sacred by the Hindus.

There are many species of *Ficus* native in the American tropics, known as Strangling Figs. The seeds of these frequently germinate on the branches of other trees, sending aerial roots downward and developing slender stems which grow about the supporting plant. Eventually the roots enter the ground and become established there. The stems, enlarging and often anastomosing, grow tightly around the supporting plant, which is often strangled and killed.

All these plants have a milky juice which may be made into **rubber.** The juice of the India Rubber Tree, *Ficus elastica,* is used in this way.

The **Banyan** tree is another species of *Ficus.* (R.M.W.)

FIG INSECT. Chalcid Fly.

FIGWORT FAMILY. Scrophulariaceae. This family contains some 2500 species, most of which are herbs or shrubs. Its members are numerous in temperature regions, where many of them are common plants, as for example mullein, "butter-and-eggs," speedwell, and lousewort. Annuals, biennials and perennials are found in the family.

The flowers are zygomorphic, or bilaterally symmetrical, with the **calyx** and **corolla** both tubular and each composed of four or five lobes. In many plants of this family the corolla is distinctly 2-lipped, as in the Snapdragon. Usually there are four **stamens,** which are inserted on the corolla tube. The **ovary,** composed of two united **carpels,** becomes a dry capsule containing many small seeds. The flowers of this family are mostly pollinated by insects, such as bees, wasps, and flies, which seek the nectar secreted in a disk at the base of the ovary.

Many members of this family show a tendency towards parasitism. In these, the seed on germinating sends out a root which comes in contact with the roots of another plant, commonly a grass. On making this contact, the root sends into the grass root absorptive organs or haustoria, which take from the host certain materials in solution. The parasite grows into an ordinary green-leaved plant capable of carrying on **photosynthesis,** but with a root development insufficient for its own needs. Such plants are only partially parasitic.

In this family are found many plants grown by man as ornamentals. Some, such as Foxglove (*Digitalis*) and Veronica, are hardy biennials or perennials; others, like Snapdragon (*Antirrhinum*), are not hardy; while *Calceolaria,* a native of South America and Mexico, is a hothouse plant grown for its bizarre sac-like flowers of brilliant color. Drugs of medicinal value are also found in several plants of this family, the most important being **digitalis,** from species of foxglove. In early days many species were used as a source for home-made brews. Others are poisonous herbs. (R.M.W.)

FILAMENT. This is the direct heated type of **cathode** used in various electron **tubes.** It is also the heated element of the common electric **lamp.** (L.R.Q.)

FILAR MICROMETER. The filar micrometer is an instrument for measuring small distances in the field of an **eyepiece.** It consists fundamentally of two parallel wires, one of which is fixed and the other capable of motion in the direction perpendicular to its length by means of an accurately cut screw. The pitch of the screw is carefully determined for various temperature conditions and the head of the screw is graduated so that whole revolutions and fractions thereof may be read.

For astronomical purposes the filar micrometer has some modifications from the instrument as used for ordinary measuring purposes. In the accompanying figure we have AB a plate of brass carrying two wires H and F which are accurately perpendicular to each other. This plate may be rotated and the index I sweeps over a circle graduated in degrees, with a vernier reading fractions of a degree. A second plate CD may be moved over the

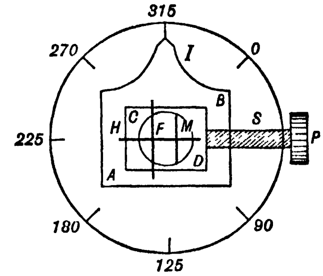


Diagram of filar micrometer.

surface of the first plate by means of the accurately calibrated screw S with the graduated head P. This plate carries on its lower surface, so that it will be practically in the same plane as F, a wire M which is set accurately parallel to F.

This instrument is so mounted that F and M are in the focal plane of the objective of a **telescope** with the optic axis of the instrument passing through the center of the opening in AB. When so mounted the filar micrometer is one of the most valuable instruments for measurement of small angular distance.

For the study of **double stars** the first adjustment of the instrument is to point the telescope at a star, preferably near the equator, and rotate the instrument until the star will move, due to the rotation of the earth, along the wire H. H, being now parallel to the equator, the reading (R_1) of the index is taken. Next the wires M and F are placed in coincidence and the head reading (D_0) taken. The telescope is then directed at the double star under investigation and rotated until H passes through both stars and the reading (R_2) of I is taken. Then holding one component of the pair of stars on F the screw is turned until M passes through the other star. The reading (D_1) of the head is taken, account being taken of the number of whole revolutions in the process. R_2-R_1 is defined as the **position angle** of the double star, and D_1-D_0 (when converted into angular units) is the distance.

The filar micrometer may also be used to determine the position of one astronomical body relative to another close object whose **spherical coordinates** are known. For this purpose the wire H is first held at setting (R_1), (i.e., parallel to the **celestial equator**), the wire F held on one of the two objects and the wire M set on the other. The distance thus measured is parallel to the equator (i.e., is proportional to difference in **right ascension** of the two objects). The instrument is then rotated through 90° and the difference in **declination** may be measured. (W.K.G.)

FILARIASIS. A parasitic disease of the tropics caused by various species of *Filaria,* a genus of **nematode** or thread worms. The parasites are commonly found in tropical countries but cases of infection have been reported in the Southern states. Both anopheline and culicine **mosquitoes** serve as intermediate hosts for the parasites. The adult forms develop in the human body after larval forms are transmitted by the bite of the infected mosquito. The incubation period is usually one year or less.

Symptoms depend on the degree of infestation and the parts of the body involved. The parasites show a predilection for the lymphatic structures. High fever, **lymphangitis** and swelling of the **lymph** nodes are common.

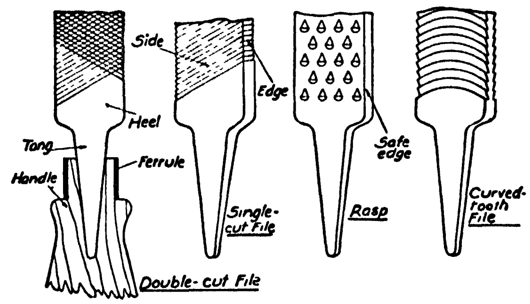
After repeated attacks permanent thickening of tissue occurs accompanied at times by great swelling of the affected parts. The swelling is caused by blockage of

the lymph channels by the parasites obstructing the flow of lymph.

When the legs are involved the condition is called **elephantiasis,** as the legs become tremendously swollen with thickened, fissured skin. The external genitals, especially the scrotum, may be similarly involved.

The disease is difficult to treat. No chemotherapy is effective against filaria. Pressure bandages and surgical treatment of elephantiasis are used. (R.S.M., D.M.H.)

FILE. A cutting tool for smoothing surfaces, breaking corners, removing burrs, and sharpening tools. The cut of a file denotes the degree of coarseness and the character of the teeth. Single-cut files have single rows of parallel teeth extending the length of the file; double-cut files have two parallel rows of teeth crossing each other; rasps have individual, or disconnected, teeth, as shown in the figure.



Types of file.

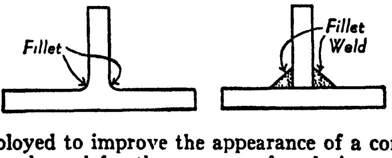
A mill file is rectangular in section, and is single-cut and tapered in both width and thickness. A flat file is like a mill file, but is double-cut. A hand file is double-cut, of parallel width and tapered thickness, and has a safe edge (one which is smooth and has no teeth). Half-round files are usually double-cut, with one flat and one curved surface. Round files are of circular, tapered section, and may be single or double-cut. Three-square and hand saw files are tapered and have a triangular cross-section, and are used for filing to sharp corners and for saw filing and sharpening. (H.C.H.)

FILE JIG. **Jigs and Fixtures.**

FILIBRANCHIATA. **Lamellibranchiata.**

FILICALES. **Paleobotany.**

FILLET. Fillet is the term employed to describe a concave section of a body which is used to reinforce a re-entrant angle formed by the intersection of two plane surfaces. It is purposely incorporated in patterns from which **castings** are to be made, since lines of stress radiating from sharp edges and corners are set up in the casting during cooling. These will be prevented, and the casting made measurably stronger, if the outside edges are rounded, and the inside filleted. Filleting is



also employed to improve the appearance of a corner, or hide a crack, and for the purpose of replacing an angularity with a smoothly rounded surface. An aircraft wing is faired into the fuselage by fillets. The junction of two parts, such as plates at right angles to each other, is often made with a weld of the fillet type, in which a small fillet of welding metal is laid down in the angle created by the intersection of the surfaces of the plates. (F.T.M.)

FILM AND FILM PROCESSING. **Cameras, Motion-Picture.**

FILM BASE. Photographic film base is made by combining a cellulose ester, or a mixture of cellulose esters, with a plasticizer, suitable solvents, thinners, and stablizers into a viscous liquid or *dope.* The film is cast, or formed, by flowing or spraying the dope in a thin layer onto a large, heated, slowly revolving chromium- or silver-plated drum. As the drum rotates, a portion of the solvent evaporates, causing the layer to set sufficiently, so the layer can be stripped from the drum before a complete revolution is made. Film base is dried and wound into rolls 50″ wide and 2000′ long. The thickness of the sheet varies according to the type of film and purpose for which it will be used. Roll film must be flexible and thin to allow it to be wound through the camera. Motion-picture film should be flexible enough to pass through the camera, or projector mechanism, yet sufficiently thick to prevent sprocket perforations from becoming torn during operation. Cut sheets have to be thick enough to lie flat in the filmholder and keep from curling during processing and storage. Representative thicknesses for film base are:

Roll film ..	85 microns
Motion picture film	140 "
Cut sheet	200 "

Since the solvents evaporated from the film base are inflammable and static electricity is generated during the casting operations, it is necessary to carry out the operation in sealed machines, in the absence of air or oxygen, in order to safeguard against the danger of explosion. The static charge is picked up by a series of small metal balls with short chains that are attached to metal rods which are grounded.

In modern film-casting machines the substratum layer, a bonding layer between film base and emulsion, and an antihalation backing are put on the base before it leaves the machine.

Two types of film base are manufactured: the cellulose nitrate used for professional motion pictures, and the safety base (noninflammable) used for professional cut sheet, amateur roll, and amateur motion-picture films.

Cellulose-nitrate base is made by treating cleaned cotton linters from upland cotton with a mixture of nitric acid, sulfuric acid and water at 40° C. with constant agitation for 20 minutes. The nitrated cotton is then washed, neutralized, bleached and dried. For safety, cellulose nitrate is moistened with alcohol and kept in metal drums.

During the operation, the cellulose molecule which contains several hundred glucose units, each unit of which has three replaceable hydroxy groups, is nitrated so that two and a fraction of the hydroxy groups are replaced by nitrate groups, or until the nitrogen per glucose unit ranges from 11.6–12.2%.

Cellulose nitrates mixed with camphor or triphenyl phosphates, as the plasticizers, and dissolved in solvents like acetone, alcohol, and toluene, forms a solution or dope which may be further thinned to proper coating viscosity.

Cellulose acetate is prepared by treating cellulose with an organic acid anhydride, an organic acid as diluent, and a catalyst. Cotton linters, treated with acetic anhydride, glacial acetic acid and sulfuric acid, are converted to cellulose acetate. The triacetate, first formed, is partially hydrolyzed until the product contains 35–40% acetyl, or two and a fraction acetyl groups, per glucose unit. The important steps in the manufacture of the acetate are: acetylation, hydrolysis, precipitation in water, neutralization, washing, centrifuging, and drying. Because cellulose acetate has a slow burning rate, it is used in the manufacture of safety film.

Safety film is made by mixing hydroxy cellulose esters with high-boiling organic plasticizers, as dibutyl phthalate, tri-phenyl, or tricresol phosphate, or dibutyl sebacate and solvents that are halogenated compounds—like propylene chloride, trichlor ethylene, and ethylene chloride, with a mixture of alcohols as methyl, ethyl, propyl, iso-propyl, -butyl and -amyl alcohols. Acetone and hydrocarbon thinners like toluene are also added.

Safety-base film can also be prepared by mixing cellulose esters of organic acids as cellulose-acetate and cellulose-propionate, or by using mixed esters as: cellulose acetate-propionate, or cellulose acetate-butyrate.

Cellulose ester solutions are concentrated and very viscous. They flow to a limited degree only. Actual thickness, during casting, is governed by a scraper.

Because of the low inflammability and the many improvements made in physical and mechanical properties during recent years, acetate and safety films have very largely replaced nitrate film. (S.M.T.)

FILM THEORY OR BOUNDARY LAYER THEORY. The film theory as applied to heat or mass transfer has to do with the analysis of the physical way in which material or heat is transferred across a phase boundary where one or both of the phases may be flowing fluids. Examples of such a transfer would be heat flowing from a pipe to water moving inside, or water vapor passing from a wet surface into an air stream flowing over it. Any study of such processes must be concerned primarily with the major resistance to the flow. It is known that transfer by convection (heat) or mixing (mass) is very much faster than by conduction (heat) or diffusion (mass). If any part of the process involves conduction or diffusion, then this part will undoubtedly offer the greatest resistance to the transfer and hence will be the controlling variable.

Even though the fluid be moving past the surface in a turbulent manner, there will still be, next to the surface, a relatively stagnant *film* of the fluid. Through this film the heat or mass must pass, respectively, by conduction or by diffusion. Calculations involving transfer of heat or mass into a flowing stream are mainly concerned with the effective thickness and the properties of the film. Methods of increasing the rate of transfer are usually based on changes designed to reduce the film thickness or to change the properties of the fluid and hence increase the rate of transfer. Increasing the turbulence of the fluid tends to scrape off the film, thereby making it thinner; and raising the temperature (for liquids) lowers the viscosity of the film and makes it more easily rubbed away by the flowing fluid. A'so, raising the temperature increases the rate of diffusion, and usually increases the heat conductance.

The actual film thickness is seldom known, but the way in which various factors (such as the viscosity, velocity, density, etc., of the fluid) affect it are often known, so that experimentally determined values for the rate of transfer under one set of conditions can usually be used to calculate the rate under a different set of conditions. (See **Heat Transfer.**) (D.E.M.)

FILTER AID. Filtration.

FILTER, CLARIFYING. Filtration.

FILTER, FREQUENCY. A filter is a frequency discriminating network designed to select or pass certain bands of frequencies with low attenuation and cause very high attenuation to other frequencies. They are among the most important components of most of our communications systems. In the common radio **receiver** filters are used to smooth out the pulsating direct current from the **rectifier** to give a steady output of the **power supply.** In the **superheterodyne** filters in the **intermediate frequency** stages give the desired selectivity. Telephone **carrier** circuits are possible because of filters which are used to separate the various channels and route the signals to the proper paths. While filters are used very widely, the telephone systems are probably the biggest users. The ordinary tuned or resonant circuit might be regarded as a special form of filter but is not commonly considered as such since it does not have a flat pass band.

Filters may be classified according to their characteristics (e.g., low pass, high pass, band pass) or according to their circuits (e.g., ladder, lattice, π and T). A low-pass filter passes all frequencies below a certain value, known as the cut-off frequency, with very little attenuation and then produces high attenuation for all above this value. A high-pass filter passes all above the cut-off frequency and a band-pass filter will pass a band or bands of frequencies and produce attenuation for all frequencies outside these pass regions. Filters are made, normally, of combinations of series and shunt elements which are as pure reactance as can be economically attained, the purer the reactance the better the filter. Fig. 1 shows the basic or prototype circuits for low-,

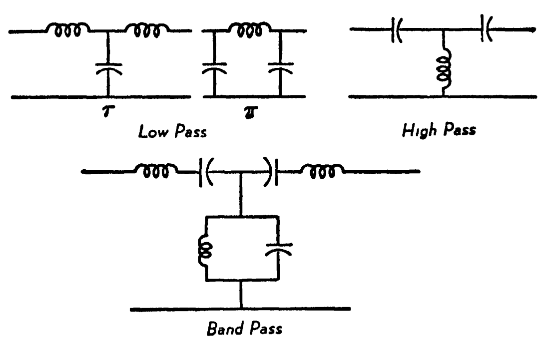


Fig. 1. Typical filter circuits.

high-, and band-pass ladder type filters. For more perfect action several sections may be connected in tandem, producing a ladder appearance. These sections may be connected as T or π circuits as shown. While these simple circuits are adequate for some purposes most filters are composed of several sections, each introducing a specific characteristic. A discussion of the low-pass T connected filter will serve to illustrate the usual practice. The prototype shown will cause little attenuation up to the cut-off frequency but neither will it cause a high attenuation just above the cut-off, the attenuation increasing very gradually. To overcome this difficulty a section known as a derived section is connected in series with the prototype. This derived section, shown in Fig. 2, gives a very high attenuation at the resonant

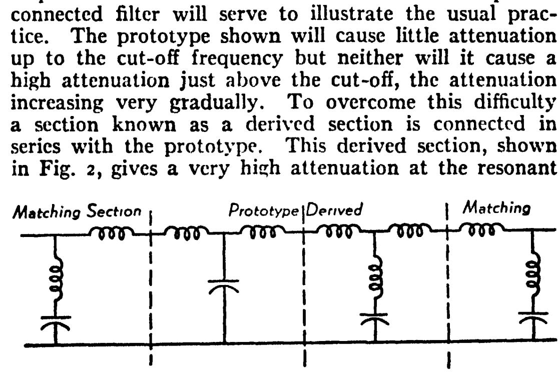

Fig. 2. Composite low-pass filter.

frequency of the shunt branch. If this resonant frequency is near the cut-off frequency the attenuation will rise rapidly at cut-off. Unfortunately this section does not keep a high attenuation as the frequency is raised so it must be used with the prototype to give high attenuation at all frequencies above the cut-off. Often several derived sections, each having a different resonant frequency for its shunt branch, are used. The input and output impedance characteristics of these sections are not very satisfactory so a matching section is connected on each end to correct this. All of these various sections are designed to match one another and to have the same

cut-off so the resulting filter, called a composite filter, will have a low attenuation pass band with no irregularities and then a high attenuation for all frequencies above this band. Other types of filters are built up in a similar manner. Quartz crystals (see **Crystal**) are equivalent to **resistance, capacitance** and **inductance** networks having a very high Q so are ideal for filter components. Through the use of these crystals telephone carrier filters may be made to very close limits and thus many more carrier channels may be superimposed on the lines. These filters usually use a lattice type connection. (See Fig. 3.) A brief outline of the

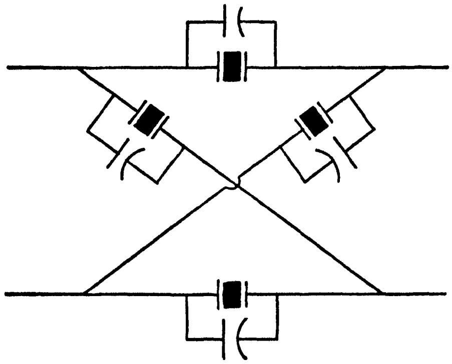

Fig. 3. Lattice-connected crystal filter.

filter arrangement for a telephone line having a telegraph **channel**, a voice frequency channel and several **carrier** channels will serve to illustrate the use of the several filters discussed here. The **telegraph** signals are below the voice frequencies, and above the voice frequencies are several **carrier** channels. Each of these bands represents a separate communication which must be routed along the proper path at the terminals, all going over the same pair of line wires between stations. A high-pass filter connected across the line with its output going to the carrier equipment will allow the carrier frequencies to pass to this equipment and will block the voice and telegraph frequencies which are below its cut-off. A low-pass filter connected across the line at the same point will pass these lower frequencies and block the carrier frequencies. Then if the output of this low-pass filter feeds a high-pass filter with cut-off at the lower voice frequency the voice currents may be passed on to the phone circuits and the telegraph signals blocked. Similarly a low-pass filter may be used to pass the telegraph and block the telephone currents. The carrier currents which were routed to the carrier circuits by the first high-pass filter are then routed to their respective channels for demodulating by band-pass filters, each designed to pass one channel.

The filters used in the power supplies of various electron tube circuits usually consist of series inductance and shunt capacity, being really low-pass filters which cut out all the a-c components of the rectified voltage and current. The band-pass filters used in intermediate frequency amplifiers are double-tuned, inductively coupled circuits which pass a band very narrow in proportion to the mid frequency. (See also **Decoupling Filter.**) (L.R.Q.)

FILTER, LIGHT. A light filter is a substance or device which changes the color or intensity of the transmitted light. It is widely used in the field of photography, spectroscopy, and microscopy. Light filters, once the adjunct of trained photographers only, are now in widespread use by amateur photographers who understand that atmospheric conditions, type of object to be photographed, and distance to be included, call for careful selection of light filter for best photographic results. (See **Color Correction.**) (F.T.M.)

FILTER, MECHANICAL. Gas filters are used to separate solid or liquid particles from gases. An important application is the purification of air for human use. Although the physiological advantages secured in the breathing of clean, filtered air have long been known, only recently has the general public been able to experience the pleasure of this addition to the standard of living, through the increasing use of **air-conditioning** systems, all of which involve filtration. Especially are benefits to be gained where the air is abnormally polluted, as in passenger trains drawn by steam locomotives, in cities, or in the proximity of factories discharging a dusty waste. Many types of filters are used in the air conditioning of trains, homes, theaters, and stores, some of which are of the wet-spray types, others dry, containing mineral wool or felted pads through which the air is caused to pass, while others have oily surfaces to catch the dust. Filters are also to be found for cleaning the dust from air used in internal combustion engines, and for purifying dust or ash-laden gases from industries, and in the laboratory.

Liquid filters are used for separating solid particles from the liquid. They are used extensively in many chemical industries (see **Filtration**). In some cases the solids may be impurities; in others, they may be the product sought. It is often necessary to purify raw water by treating it chemically to precipitate the salts it may contain, or to coagulate impurities carried in suspension. Public water supply offers numerous examples of large-scale filters. A liquid filter may be made of paper, a porous membrane, or a layer of a porous material such as charcoal, coke, or sand. Two systems of large-scale filtration of raw water are practiced—one known as the slow sand filter, the other the rapid sand filter. The slow sand filter is simply a large water-tight basin containing graded sand to the depth of 3 or 4′, overlaid with 3–5′ of water. Water percolates downward through the sand bed, being removed by an underground system consisting of tile laid with open joints. After an extended period of time the effectiveness of the filter is reduced by accumulation of dirt on the filter bed, and cleaning is necessary. Then the filter is unwatered, and the top layer of sand and dirt removed for cleaning and renewal. A rapid sand filter employs a thinner filter bed, and is arranged for backwashing the bed to remove dirt. This cleaning action must be performed much more frequently than in the slow sand filter, because the rate of percolation through the bed is considerably faster. The usual arrangement of the rapid sand filter embodies a channel into which water from a sedimentation or coagulation basin flows. From this channel a number of lateral distributing gutters lead off at right angles. These distribute the water over the filter bed. Ordinarily, the filter bed will be about 3 or 4′ thick, and will be submerged to a depth of 2 or 3′. The under drain system is much more complete and effective than in the slow sand filter, and consists of a series of parallel water channels which discharge into parallel pipes, all of which are connected to a common filtered water header. Some amount of suction, or negative head, on the drain system, is permissible. (F.T.M.)

FILTER PRESS. Filtration.

FILTER, SAND. Filtration; Water.

FILTRATION, SEDIMENTATION, CENTRIFUGING, CLARIFICATION. These processes all involve the principles of separation of solids and liquids in the same system from each other. Filtration accomplishes this end by means of interposing a porous medium, usually of paper or cloth of the desired porosity, but sometimes of sand or woven metal in such a way that the solid or precipitate is retained by the membrane while the liquid filtrate passes through the pores of the membrane. In some cases both precipitate and filtrate

are recovered, whereas in other cases either precipitate or filtrate is desired and recovered and the other discarded. The separation of precipitate and filtrate may be made more complete by washing the precipitate while on the filter or by repeated sedimentation before filtering. In sedimentation the solid material settles in the liquid at a rate depending upon the diameter of the particles (assuming these to be spherical), the difference in densities between the solid and liquid, and the viscosity of the liquid. This relation was expressed mathematically by Stokes, thus, where g is the acceleration due to gravity:

$$\text{Rate of fall of particle} = \frac{2g}{9} \times \frac{(\text{Radius of particle})^2}{\text{Coefficient of viscosity}} \times \text{Difference in densities of solid and liquid.}$$

It is evident, therefore, that, in a given case the larger particles of solid settle more rapidly than the smaller, and that in two parallel cases the greater the difference in densities of the solid and liquid, and the less the viscosity of the liquid, the more rapidly sedimentation takes place. In **centrifuging,** the machines in use are designed to subject the material which is treated to the action of centrifugal force. Sedimentation and centrifuging may be utilized to separate two immiscible liquids.

In the practice of filtration, two cases may be mentioned. First, in the case where the suspended solids to be recovered represent a *small* percentage of the total material to be treated. The filter cake is built up with a force and at a rate which depend upon the pressure with which the material is fed to the filter. It is desirable to start with a moderate to low pressure, and to

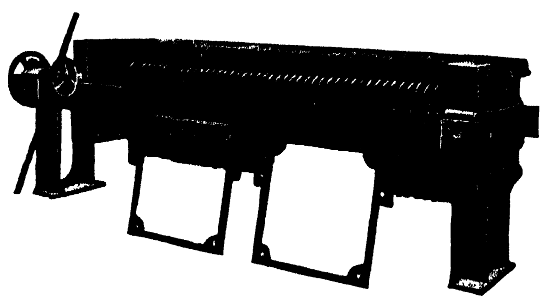

Plate and frame filter press (open), corner feed washing type

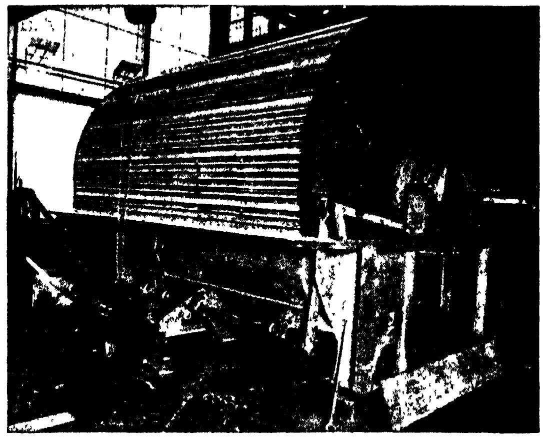
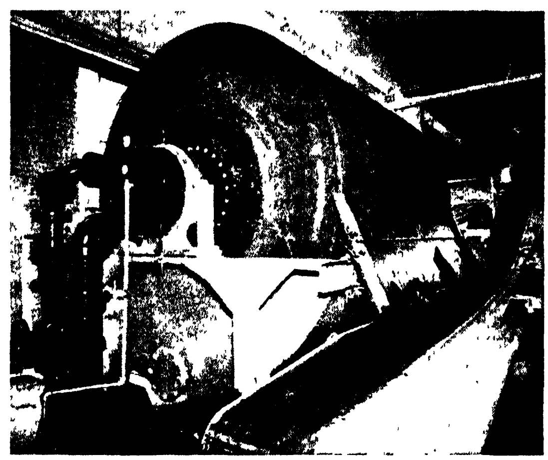
increase the pressure gradually as the resistance of the filter cake increases. In this way a practically constant rate of flow of filtrate is maintained during the desired interval until removal of cake is demanded because of the slow rate of flow at the maximum pressure. Second, in the case where the suspended solids to be recovered represent a *large* percentage of the total material to be treated. The formation of the filter cake will depend largely upon the kind of solid particles composing the precipitate. When these are granular and of the same size throughout, the resistance builds up gradually and the pressure should be moderate to low and increased as the resistance increases. When the solid particles are gelatinous, or are of uneven size, the increase in resistance to filtration and the decrease in rate of flow of filtrate occur relatively quickly. High initial pressure is to be avoided on account of the increased compacting effect, due to the force with which the particles come in contact with the filtering medium. It is frequently arranged to build up a layer of the precipitate and to utilize this layer as filtering medium. In such cases, since the initial filtrate is cloudy, it is returned to the filter after the filtrate runs clear. Another device to increase the rate of filtration of fine particles is to build up a layer of inert granular material.

For filtering gelatinous materials, such as ferric or aluminum hydroxides, which tend to clog the filter, use is made of filter aids. These are usually finely divided inert materials which are easy to filter and which have a large area per unit volume. Diatomaceous earth and



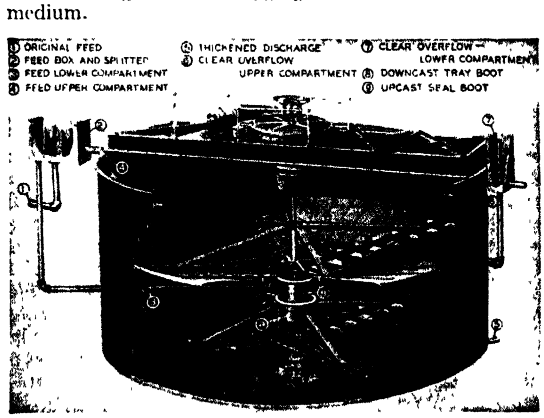
Conkey rotary vacuum filter in process of assembly for installation on sewage sludge at Detroit, Mich. (*Filtration Equipment Corporation.*)

paper pulp are examples. The filter aid is mixed with the solution to be filtered. The gelatinous or slimy



Conkey rotary vacuum filter in operation on sewage sludge at Elmira, N. Y. (*Filtration Equipment Corporation.*)

material tends to stick to the filter aid, thus keeping it from settling on and clogging the surface of the filter medium.



Dorr thickener. (*The Dorr Co.*)

The pressure utilized in filtering may be obtained by the use of negative pressure, that is, partial vacuum, or

positive pressure, either hydrostatic head or pump. Filters are of the intermittent or batch and of the continuous types. In the latter type provision is made for the continuous removal of the filter cake as it is collected on a revolving filter.

Continuous separation of suspended solids and the liquid medium is also conducted, without the use of a filtering medium, by the application of the principles of sedimentation accompanied by the continuous separate withdrawal of sedimented layer and clarified supernatant liquid at the proper rates. This method of clarification is operated on an extensive scale. One modification of this method is utilized to remove the silt from the water of the Colorado River, immense settling basins in parallel arrangement being used. (R.K.S.)

FIMBRIATE. With a ruffled margin.

FIN. A broad thin appendage, primarily an organ of locomotion, and structures of similar origin adapted for other uses. True fins are found only in fishes (**Pisces**).

The two principal kinds of fins are the median and the paired. Median fins extend from the body along the median line of the dorsal surface, around the caudal end as the tail fin or tail, and forward as far as the vent. Paired fins include a pectoral pair attached to the pectoral girdle of the **skeleton** and the pelvic pair attached to the pelvic girdle. All fins are supported by bony or cartilaginous fin rays.

The median fin is broken up in most fishes to form separate dorsal fins and a ventral anal fin in addition to the caudal fin or tail. A caudal division of the dorsal portion is sometimes developed into the fleshy adipose fin. The tail fin may be heterocercal or homocercal. The former type has the end of the vertebral column extending into or toward its dorsal margin while the latter is evenly developed above and below the skeletal axis.

Paired fins are variously modified to form sensory lobes or supporting structures and the pelvic pair of some male sharks bear slender lobes, the claspers, which are thrust into the cloaca of the female during copulation. (A.W.L.)

FIN, AIRPLANE. A fixed or adjustable airfoil, attached to an aircraft approximately parallel to the plane of symmetry, to afford directional stability; for example, tail fin, skid fin, etc. (F.T.M.)

FIN FOLD. A projecting ridge of the body wall in the lancelets which extends the lateral surface of the body and aids in swimming. The ridge follows the same course as the fins of fishes, along the median line of the back, around the caudal end of the body, forward ventrally to the **atriopore** where it forks and continues forward as a pair of ventrolateral folds.

A fin fold has been supposed to represent the earliest stage in the evolution of the locomotor appendages of **vertebrates.** At first a keel for **equilibrium,** extending as a single fold along the back and over the tail, it divided to pass around the cloaca and extend forward on the ventral surface as a pair of folds. By the growth of cartilaginous rods for support and of muscle for control and the dropping out of portions of the fold, the median and caudal unpaired fins and also the paired fins of fishes developed. In the acquisition of a terrestrial habitat the unpaired fins were no longer useful, while further changes in the bony skeleton and musculature adapted the paired limbs first for supporting the body and then for propelling it. This theory has recently been criticized on the basis of studies of early fossil vertebrates. (A.W.L.)

FINCH. Aves, Passeriformes. Seed-eating birds (**Aves**) of many species, found chiefly in the northern hemisphere but to a limited extent in Africa and South America. They are small to moderately large and have a strong beak, usually conical and in some species very large.

In addition to the species whose names indicate their relation with the group, such as the greenfinches and the chaffinches, the finches include birds with distinctive names. The **grosbeaks, cardinals, brambling, siskins, linnets, redpolls, sparrows, canary,** and **crossbills** belong here. (A.W.L.)

The Cardinal (redbird), one of the many species of finches. The Cardinal is bright red, with throat and a ring around the beak black. It has a conspicuous crest, and light red bill. The female is duller.

FINFOOT. Aves, Gruiformes. Birds (**Aves**) of a few species found in Africa, South and Central America, and the Oriental region. They are similar to the cormorants in form and frequent the water. The toes are lobed. (A.W.L.)

FINGER. Any of the second to fifth digits of the pectoral appendage of primates. (See **Hand.**) (A.W.L.)

FINGER LAKE. A glacial U-Valley or rock bowl which forms the basin for a fresh-water lake. Because of the character and origin of the basin, finger lakes are relatively long and narrow. Type locality, the finger lake region of New York State. (R.M.F.)

FINITE DIFFERENCES. **Calculus of Finite Differences.**

FIORD. A fiord is a glacially overdeepened **valley,** usually narrow and steep-sided, extending below sea level and occupied therefore by salt water. Typical fiords are to be found in Alaska and Norway; their depths, sometimes as much as 4000′, indicate that they are glaciated valleys which have been invaded by the sea after the disappearance of the glaciers. The word fiord is a variant of the Norwegian term for these features, *fjord.* The long fiord-like bays of the New England coast line are sometimes referred to as fiards. (R.M.F.)

FIR. **Conifers.**

FIRE. **Combustible; Combustion.**

FIRE BRAT. Insecta, Thysanura. A wingless **insect,** *Thermobia domestica,* clothed with silky scales and bearing long antennae and three slender filaments at the opposite end of the body. Related to the **silverfish** but found in warm places; economic importance and control similar. (A.W.L.)

FIRE DAMP. **Methane.**

FIRE EYE. Aves, Passeriformes. A common species of **ant bird** in Brazil. (A.W.L.)

FIREBALL. Fireball is a term used in astronomy to designate those **meteors** which are large enough to be apparently brighter than the **planet Jupiter.** They frequently leave a trail which may be visible for several minutes. Not infrequently a distinct sound is heard either during, or shortly after, the observation of a fireball. (W.K.G.)

FIRE-BRICK. Fire-brick is a type of brick capable of withstanding high temperatures and is used to line flues,

stacks, furnaces, etc. Good resistance to heat flow is not to be secured simultaneously with refractoriness—indeed, the most refractory bricks generally have the highest thermal conductivities. Where necessary, insulation is added to minimize heat leaks. It is important for the refractory brick to be satisfactory on a number of points in addition to refractoriness, for resistance to melting is only one of several requirements to be met. Among these might be cited resistance to erosion by ash-laden gases, and to the fluxing action of molten slag. A good refractory should not spall badly under rapid temperature changes. The structural strength of fire-brick should hold up well as its temperature approaches the fusion temperature.

Modern installations often impose furnace conditions so severe that refractories other than fire-clay are needed. High aluminum and silicon carbide refractories are typical of these. The heat conductivities of the super-refractories are larger than those of fire-clay brick, and such construction should be backed up with high temperature insulation. Silicon carbide blocks are the most refractory and have the quality of resisting clinker adhesion better than ordinary fire-brick. Their fusion temperature is about 4000° F.

Clay fuses at from 2800° to 3200° F., the upper limit being for flint clay and the lower for the plastic form which, due to its cementing qualities, is especially valuable in fire-brick manufacture. Red brick is not suitable for refractory service, nor is insulating brick. There are several fire-clay furnace **cements** on the market that are adaptable to monolithic lining. The standard size of fire-brick and insulating brick is 9″ by 4½″ by 2½″. (F.T.M.)

FIRECLAY. This term is chiefly used by British geologists to designate the leached **clays,** rich in **silica** and **alumina** and low in **alkalies** and lime, which lie directly beneath coal beds. These clays are of economic importance because they are refractory, and do not melt when heated to high temperatures. (R.M.F.)

FIREFLY. Insecta, Coleoptera. Soft-bodied **beetles** with a luminous organ in the abdomen. The flashing of these insects apparently enables them to find mates. Also called lightning bugs. (A.W.L.)

FIREWALL. Industrial or commercial buildings, standing adjacent, with common division wall, may be required to have special attention given to this wall, as to apertures, thickness and material, so as to prevent ignition or transmission of conflagration from one building to another. Such a wall would be a firewall.

Aircraft having the **engine** mounted in the nose of the **fuselage** are required to have a firewall. This consists of a bulkhead of sheet steel, dividing the engine compartment from the remainder of the fuselage. (F.T.M.)

FIRN. **Cirque.**

FIRST ANGLE PROJECTION. **Orthographic Projection.**

FIRST DETECTOR. **Superheterodyne.**

FISCHER-TROPSCH PROCESS. **Catalysis.**

FISH. **Pisces.**

FISH FLY. Insecta, Neuroptera. Species related to the **corydalus.** The **larvae** are aquatic and the adults are found near water. (A.W.L.)

FISH LOUSE. Crustacea, Copepoda. Minute marine and fresh-water animals parasitic on fishes. (A.W.L.)

FISH MOTH. **Silverfish.**

FISHER. **Marten.**

FISHERIES. **Pisciculture.**

FISHER'S z DISTRIBUTION. Fisher's z distribution was derived by R. A. Fisher in 1924.

$$P_z dz = \frac{2n_1^{\frac{n_1}{2}} n_2^{\frac{n_2}{2}}}{B\left(\frac{n_1}{2}, \frac{n_2}{2}\right)} \frac{e^{n_1 z}}{(n_1 e^{2z} + n_2)^{\frac{n_1+n_2}{2}}} dz, \quad -\infty < z < \infty$$

$z = \frac{1}{2} \log \frac{s_1^2}{s_2^2}$, $B\left(\frac{n_1}{2}, \frac{n_2}{2}\right)$ is the **Beta function,** s_1^2 is the estimated **variance** with n_1 degrees of freedom and s_2^2 is the estimated variance with n_2 degrees of freedom. The z distribution is used in the **analysis of variance.** The z distribution becomes the **normal curve** in case $n_1 = 1$, $n_2 = \infty$ after the transformation $z = \frac{1}{2} \log \chi^2$, $0 \leq \chi^2 < \infty$; it becomes the χ^2 distribution after the transformation $e^{2z} = \chi^2$, $n_1 = n$, $n_2 = \infty$, $0 \leq \chi^2 < \infty$; and becomes **Student's t distribution** after the transformation $z = \frac{1}{2} \log t^2$, $n_1 = 1$, $n_2 = n$, $0 \leq t < \infty$. In the limit as n_1 and $n_2 \to \infty$ in any manner whatever, the z distribution approaches normality with asymptotic **mean** $\frac{1}{2}\left(\frac{1}{n_2} - \frac{1}{n_1}\right)$ and asymptotic variance $\frac{1}{2}\left(\frac{n_1 + 1}{n_1^2} + \frac{n_2 + 1}{n_2^2}\right)$. The z distribution is easily transformed into **Snedecor's F distribution.** Tables of the z distribution have been calculated. (L.A.A.)

FISSION. A process of **reproduction** by the subdivision of the parent body into two or more approximately equal parts which become independent individuals.

Fission is a common form of reproduction in the 1-celled animals. Division of the cell into two parts known as binary fission, is accomplished by **mitosis,** often of a modified form. In very simple species such as *Amoeba* reproduction is no more than cell division, but in species with constant body form each half of the cell differs from the other and reproduction is not complete until it has undergone a reorganization with the development of all structures characteristic of its kind.

Some protozoans (**Protozoa**), notably parasitic species, go through a process of subdivision into a number of parts simultaneously. This process is multiple fission or sporulation.

Fission occurs in multicellular animals of simple structure, including **polyps** and flatworms, by a gradual reorganization accompanied by the constriction and breaking of the body. (See **Radioactive Changes; Atomic Bomb.**) (A.W.L.)

FISSURE IN ANO. A break or crack in the skin just internal to the margin of the **anus.** It is an exceedingly common condition, one that usually complicates hemorrhoids and causes excruciating pain. The crack becomes infected, is raw and tender. Simple early cases can be treated locally with success. Many cases cannot be cured without operation. (D.M.H.)

FISTULA. A deep, chronically infected tract or artificial tube extending from the surface of the body deep into its tissues. Fistula in ano is a fistula which is located around the anal margin, which runs upward through the deep tissues around the **rectum,** usually opening into its lumen. Fistula in ano follows abscess formation around the lower rectum. Surgery is required for its cure. (D.M.H.)

FIT. The dimensional relationship between mating parts. In any machine or device there are certain relations between the dimensions of the component parts that are essential if the unit is to function properly. In a drilling machine, for example, the spindle should rotate freely but without any perceptible shake in the bushings. The bushings, on the other hand, should fit tightly in the frame. The difference in size between the bore of the bushing and the diameter of the shaft is referred to as clearance; the difference in size between the outer diameter of the bushing and hole in the frame is referred to as interference since the bushing is larger than the hole. Both of these intentional differences in the sizes of mating parts are termed allowances. Clearance is positive, interference negative, allowance.

The American Standards Association has adopted eight classifications of fits which are described in A.S.A. Bulletin B 4a-1925. A class 1 loose fit has a large allowance, provides for considerable freedom where accuracy is not essential, and is used in agricultural and mining machinery. A class 2 free fit has a liberal positive allowance, and is used as a running fit for speeds higher than 600 rpm. A class 3 fit has a medium positive allowance, and is used for the more accurate machine tool and automotive parts. A class 4 snug fit has a zero allowance, necessitates considerable precision, and is the closest fit that can be assembled by hand. A class 5 wringing fit has a zero to negative allowance, and gives practically metal-to-metal contact. A class 6 tight fit has slight negative allowance, requires light pressure to assemble, and is used for gears, pulleys, and extremely long contacts. A class 7 medium force fit has negative allowance, requires considerable pressure to assemble, and the parts are considered permanently assembled. A class 8 heavy force and shrink fit has considerable negative allowance, and is used for press fits in steel or for shrink fits where heavy force fits are impractical.

Four classes of screw thread fits are described in the A.S.A. Bulletin B 1.1 1935. A class 1 fit is quite loose, and is recommended where shake or play is not objectionable, and where rapid assembly is desired. A class 2 fit is used for the great bulk of commercial screw thread products, and represents a high quality of fit. Classes 3 and 4 represent extremely close fits, and are used only where freedom from vibration and play are absolutely essential. A class 4 screw is not yet adapted to quantity production, on account of the extremely small tolerances permitted. (H.C.H.)

FITCHEW. Polecat.

FITTIG REACTION. The formation of aromatic hydrocarbons from aryl or aryl and alkyl bromides by the use of sodium, e.g., bromobenzene plus ethyl bromide plus sodium forms ethylbenzene plus sodium bromide ($C_6H_5Br + C_2H_5Br + 2Na \rightarrow C_6H_5 \cdot C_2H_5 + 2NaBr$). (See **Würtz-Fittig Reaction.**) (R.K.S.)

FIX. In **navigation,** a position of a ship, as determined by the intersection of two or more **lines of position,** is known as a fix. Since lines of position are determined in all of the observational types of navigation, **pilotage, celestial,** or **radio,** it is obvious that we might define fix as any position of a ship determined by observational means.

Since all observational methods are subject to unavoidable errors of observation, a line of position is not strictly a line, but is a band of constant width, as in the case of a line determined by celestial navigation, or of width which increases from the point of observation, as in the case of pilotage or radio navigation. Hence, a fix is not strictly a point, but is a polygon whose area depends upon the accuracy of the observational material employed in determining the "line." With two lines of position, the area will be a quadrilateral and the area will be a minimum when the lines are at right angles to each other. Three lines of position will seldom, in practice, intersect in a point, but will bound a triangle, and the standard symbol for indicating the position of a fix on a geographic plot, is a triangle with a dot at the center. This symbol is used no matter how many lines are used in determining the position, the point being the point of intersection of two lines, or the center of the polygon when more than two lines are used.

When the observations for the lines of position can be taken simultaneously, a fix can be immediately determined for the instant at which the lines were observed. Simultaneity of observation is seldom possible and the question of movement of the ship between observations must be carefully considered. It is safe to say that if the ship does not move more than 2 miles between observations, the fix may be considered as the intersection of the lines as directly plotted, with the time of the fix recorded as the average of the times of observation.

If the ship has moved appreciably (more than 2 miles) between observations, the method of running fix must be employed. To obtain a running fix, the time of the fix is usually selected as that of the time of observation of some one of the lines, and the other lines are advanced or retarded to that line by standard **dead-reckoning** methods. In certain particular cases, e.g., when a noon position is desired and the only observations available are one before noon and the other after noon, both lines are moved, one forward and the other back, to the desired time. Before considering a specific case it should be remembered that, by definition, a line of position is a line on which a ship is situated. For the purpose of moving the line, any conveniently located position may be selected, advanced or retarded by dead reckoning, and a line drawn parallel to the observed line through the DR point will be the advanced line. The use of parallel rulers is convenient, but not essential, for this purpose. In case the line of position is appreciably curved, due to the fact that the center of the circle of position is relatively close to the observer, the position of the center must be found, advanced by dead reckoning, and a new circle drawn, using the radius of the original circle.

The following situation illustrates the method for obtaining the running fix of a line of position obtained by celestial navigation and one obtained by pilotage:

At 0620 a ship is in L (latitude) = 42° 20′ 8 N & Lo (longitude) = 68° 20′.1 W, and is proceeding at 16 knots on course 257°. At 0620 a line of position is obtained by celestial navigation, with the line running in the direction

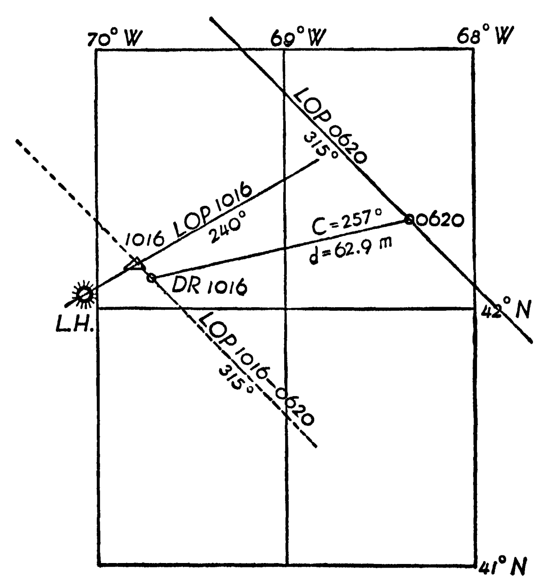


Fig. 1. Scale diagram on mercator plotting sheet.

135°–315°. At 1016 a lighthouse in L = N 42° 02′.4 & Lo = 70° 03′.7 W is sighted on bearing 240°. The 1016 position of the ship is desired.

In Fig. 1 the problem is plotted on a **mercator plotting sheet** with all lines labelled in accordance with U. S. Navy procedure. Through the 0620 position the line of position (LOP) is drawn in the 135°–315°. The course line is drawn in direction 257° and the 1016 DR position plotted on this line 62.9 miles (the distance run at 16 knots between 0620 and 1016) from the 0620 position. Through this DR position a line is drawn parallel to the 0620 LOP, thus giving the advanced line of position. Through the lighthouse a line is drawn in the 240°–060° direction and this is the 1016 LOP. The 1016 fix is determined to be at L = 42° 09′.6 N & Lo = 69° 46′.5 W. Other examples of obtaining and plotting lines of position and fixes will be found in the articles on **Celestial Navigation, Pilotage,** and **Radio Navigation.** (W.K.G.)

FIXATION. The process of removing silver halides remaining in photographic emulsions after development is termed "fixation." Since the developed emulsion contains metallic silver and undeveloped silver halides that are light-sensitive, it is necessary to remove the latter in order to stabilize the image. This is accomplished by converting the silver halides into complexes that are readily soluble in water. In addition, the emulsion is swollen, due to alkalinity of developer and imbibition of water, and because it contains partially oxidized developing agents that may produce stain, it is usually advisable to combine with the fixing agent, substances that stop development, prevent stain and harden or retard the swelling of gelatin.

Fixing Baths. According to their function, the components of fixing baths can be divided into the following heads:

1. Silver halide solvent. Many silver halide solvents have been suggested as fixing agents. Among these are:

Sodium thiosulfate (common hypo)	Sodium cyanide
	Sodium sulfite
Potassium thiosulfate	Ammonia
Ammonium thiosulfate	Sodium thiocyanate
Sodium chloride (brine solution)	Thiourea
	Potassium iodide
Potassium cyanide	Thiosinanine

Of these only the thiosulfates and cyanides are important. The others are too costly or possess properties that are objectionable. The cyanides are extremely toxic but are valuable as fixing agents for emulsions that contain a high concentration of silver iodide. For silver chloride and silver bromide, the most practical agent is sodium thiosulfate, $Na_2S_2O_3 \cdot 5H_2O$, which is known as hypo. Ammonium thiosulfate is a faster fixing agent but is more expensive.

The requirements for a good fixing agent are: (1) it should dissolve silver halides without affecting the silver image, (2) the complexes formed should be readily soluble in water and yet stable, so they will not decompose during washing, (3) the agent should not cause excessive swelling or softening of gelatin.

The exact reactions for the formation of thiosulfate complexes are still unknown. However, the thiosulfate ions must combine with silver ions and form soluble complexes as:

$$AgBr + 3Na_2S_2O_3 \rightarrow NaBr + Na_5Ag(S_2O_3)_3$$

$$2AgBr + 3Na_2S_2O_3 \rightarrow 2NaBr + Na_4Ag_2(S_2O_3)_3$$

$$AgBr + Na_2S_2O_3 \rightarrow NaBr + NaAgS_2O_3.$$

In used fixing baths, it is probable that many different reactions exist in equilibrium. The exact equations will depend on the relative concentrations of silver and thiosulfate. Experimental evidence has shown that $Ag_2S_2O_3$ is insoluble, and that $NaAgS_2O_3$ is slightly soluble, while $Na_5Ag_3(S_2O_3)_4$ and $Na_4Ag_2(S_2O_3)_3$ are readily soluble. The insoluble and slightly soluble complexes are unstable, and if left in the emulsion, will decompose in time, causing silver sulfide stain.

Slightly soluble and insoluble complexes can be avoided if emulsions fixed in partially exhausted baths are immersed, for a short interval, in a fresh fixing bath. The two-bath technique insures formation of soluble complexes and is, therefore, recommended.

2. The anti-staining agent. The function of an anti-staining agent is to neutralize the alkali of developer, stop development, and prevent stain due to oxidation of developing agents carried over with emulsion. While most acids are capable of neutralizing the developer, organic acids are preferred because these have a lower degree of dissociation and do not decompose or sulfurize hypo. Satisfactory anti-staining agents include:

Acetic acid	Maleic acid
Citric acid	Sulfuric acid
Tartaric acid	Sodium bisulfite
Boric acid	Sodium bisulfate
Lactic acid	Potassium metabisulfite

For acid hardening baths, acetic acid is undoubtedly the most satisfactory. Solid organic acids, like citric and tartaric, tend to form salts with alum and reduce hardening. The acid sulfites, sodium bisulfite and potassium metabisulfite, do not possess sufficient reserve acidity to prevent precipitation of aluminum sulfite.

The bisulfites are satisfactory, however, in acid fixing baths containing thiosulfate and sodium sulfite.

Sulfuric acid is preferred in chrom-alum fixing baths for tropical processing.

3. The preservative. The addition of acids to thiosulfate decomposes the thiosulfate into sulfurous acid and sulfur, destroying the fixing bath. Sodium sulfite, because it combines with sulfur and forms thiosulfate, is used as the preservative. Besides protecting the thiosulfates from the acid, sodium sulfite also acts as an anti-oxidant and prevents the partially oxidized developing agents from staining the gelatin.

4. Hardening agents. Salts of aluminum, chromium, and iron exert hardening effects on gelatin. The alums are most satisfactory for fixing baths. The colorless aluminum alum (potassium alum) can be used in both film and paper fixing baths. Chrom alum stains paper.

The hardening action of alum is due to hydrolysis of the salt into a hydrous oxide which is adsorbed by gelatin and forms a complex that is retained even when washed with hot water.

Sodium sulfate has been referred to as a temporary hardner, although it only prevents further swelling of the gelatin.

Formalin, tannin, quinone and quinoid bodies are hardening agents that function in alkaline or neutral solutions only.

Classification of Fixing Baths. Fixing baths are classified according to their composition.

1. Plain hypo—15–40% solutions are used in cases where no hardening is necessary and where the presence of acid will alter the silver grain or change the tone of prints.

2. Neutral fixing baths. These baths contain thiosulfate and sodium sulfite as a preservative. They have some stain-prevention properties and longer life than plain hypo.

3. Acid fixing baths. Acid fixing baths neutralize the developer, stop development and assist the sulfite in preventing stain. A typical bath is:

Sodium thiosulfate	240 grams
Sodium sulfite	10 grams
Sodium bisulfite	25 grams
Water to make	1.0 liter

Baths of this type are satisfactory when hardening is not desired, or if a hardening stop bath has been employed between developer and fixing baths.

4. Acid hardening baths. These baths normally contain four components—a silver halide solvent, a preservative, an anti-staining agent, and a hardener.

The four components may be contained in one solution or obtained by mixing two solutions, a hypo solution composed of sodium thiosulfate in water, with a hardner solution containing sodium sulfite, acetic acid and potassium alum. At times *buffers,* such as boric acid or borax, are added and anti-precipitants like sodium acetate and sodium citrate are included.

A general formula that is recommended for films, plates and papers is:

Hot water (52° C.–125° F.)....	600	cc.
Sodium thiosulfate......... ..	240	grams
Sodium sulfite, desiccated....	15	grams
Acetic acid, 28%........ .	48	cc.
Boric acid......... .	7.5	grams
Potassium alum....... . .	15	grams
Cold water to make..	1.0	liter

The above bath is buffered with boric acid and produces more satisfactory hardening throughout its useful life. It hardens satisfactorily over a pH range of 4.2–6.0 and does not sludge or sulfurize until a pH of 6.5 is reached.

The working life of the bath is from 15–25 8 x 10″ prints or films, depending on whether water- or acid-rinse baths are used.

Time of Fixation. The clearing time of an emulsion is an index to its time of fixation. Most authorities agree that the time for complete fixation is twice the clearing time. Factors that affect the time of fixation are:

1. Nature of emulsion.
2. Thiosulfate concentration.
3. Nature of thiosulfate ion.
4. Temperature.
5. Agitation.
6. Degree of exhaustion.

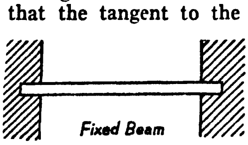
Test for Complete Fixation. Strips of unexposed photographic paper that have been fixed and washed with a batch of prints may be used for the test. The strips are partially immersed in a 0.2% sodium sulfide bath for one minute. If the strips show any yellowish-brown discoloration, they are improperly fixed. The prints should then be refixed in a fresh fixing bath. The test should not be conducted in a darkroom or near sensitive materials as the sulfide fumes produce chemical fog.

Test for Exhausted Fixing Baths. The test for exhaustion depends on the silver content of the fixing bath. The bath is considered exhausted if a 10 cc. sample treated with 1 cc. of 4% potassium iodide produces a yellow precipitate on standing. (S.M.T.)

FIXATION OF ATMOSPHERIC NITROGEN. **Ammonia; Nitrogen.**

FIXED ARCH. **Arch.**

FIXED BEAM. A fixed or restrained beam is one having the ends so firmly connected to the supports that the tangent to the **elastic curve** at the ends remains fixed in direction under varying load conditions. Theoretically, this requires the support to be absolutely unyielding. In actual practice it is impossible to attain a perfectly rigid end support, and the design of a beam on the assumption of perfect restraint would be unduly optimistic. Therefore a design intermediate between perfect restraint and perfect freedom should be adopted for built-in beams, the departure from the conditions of perfect fixity being based upon the rigidity of the end supports. Since a fixed beam under load receives an end moment where it is built in, it will be stiffer than a freely supported beam, and thus have a smaller deflection under the same load. (C.W.C.)



Fixed Beam

FIXED OILS. These are fats, compounds of **glycerin** and various complex fatty acids. (See **Acids, Carboxylic; Esters;** and **Fats.**) They are often called non-volatile oils, in distinction to the essential or **volatile oils,** which are readily vaporized by heat. It is characteristic of them that they will leave a spot when dropped on paper. Many of them remain liquid at common room temperatures, others are solid at such temperatures. Solid forms are usually called fats, a purely arbitrary distinction since slight changes in temperature will cause many of them to change from liquid to solid or vice versa.

Fixed oils, especially those of economic importance, are largely obtained from the seeds of plants. They have a high energy value, so form a valuable food if they prove palatable.

Various methods are employed to obtain the oil from the vegetable tissues. Quite commonly the seeds containing the oil are subjected to great pressures in **hydraulic presses.** This may be done without heating, but is frequently facilitated by heating the seeds, the oil being then hot-pressed instead of cold-pressed. Hot-pressing usually increases the yield but causes the product to be less valuable. A third method of obtaining the oil is by means of solvents. Following expression of the oil from the plant tissues, various methods of refining, decolorizing and deodorizing are employed.

Fixed oils are usually classified into three groups, drying, semi-drying, and non-drying oils. Often a fourth group is made of those which are usually seen in solid form, the vegetable fats, although they differ but little otherwise from the other groups.

Drying oils are those which on exposure to air form a tough elastic film. Linseed oil from **flax** seeds is one of the most important and is largely used in making paints and varnishes. **Tung oil,** obtained from the fruits of *Aleurites cordata,* is a valuable oil much used in the manufacture of waterproof varnishes and quick-drying enamels. The tree, a native of China and Japan, has been introduced into Florida. Other drying oils are nut oil, from walnut seeds, poppy seed oil, **hemp** seed oil, and sunflower oil, the latter largely a product of Russia.

Non-drying oils are those which remain permanently greasy or sticky, becoming rancid after a time. Among these oils the most important are **olive** oil, castor oil from the seeds of the **castor** bean plant, rape seed oil, **peanut** oil, **almond** oil, used medicinally, and tea seed oil.

Semi-drying oils are intermediate in nature. The principal semi-drying oils are **cotton**-seed oil, **soybean** oil, **corn** or maize oil and sesame oil. The latter is obtained from the seeds of *Sesamun indicum,* a member of the Pedaliaceae, cultivated in India, China and Japan, where the oil is much used as a food oil and for cooking.

Non-drying oils which are ordinarily solid are palm and palm-kernel oil, coconut oil, and cocoa butter. Another interesting oil of this group is macassar oil, obtained from the seeds of *Schleichera trijuga,* one of the Sapindaceae, occurring in tropical Asia. The oil was formerly much used as a potential "hair restorer," necessitating the use of removable covers, or anti-macassars, on the backs of upholstered chairs. The same tree also yields a useful timber. (R.M.W.)

FIXTURE. **Jigs and Fixtures.**

FLAGELLATES. This is a large group of organisms, of particular interest because of the position they occupy in the organic world. In this article they are treated as plants, but they are also treated as animals. (See **Mastigophora.**) They are usually 1-celled organisms, of extremely complex structure. Many of them have no cell wall of **cellulose,** lack the green pigment, **chlorophyll,** and are definitely animals. Others possess a distinct wall of cellulose and have **chloroplasts,** and are set off as plants. The separation of these two groups is not sharp, however, and some of the plant members are obviously very closely related to very similar animal forms. Therefore it is impossible to stress the differences which are used as a basis for classification. Characteristic of the Flagellates is the flagellum, a long lash-like extension from the **protoplast.** The vibrations of the flagellum propel the organism through the water, in which they usually occur.

The Flagellates are considered by many to represent the ancestral group from which higher organisms, both plant and animal, originated. Many of the animal flagellates occur as parasites in the bodies of higher animals. Some of these occur in the human body, commonly in the intestines. It has been suggested that certain species may cause severe **dysentery.** (R.M.W.)

FLAGELLUM. 1. A movable slender process arising from a **cell.** An organ of locomotion of certain one-celled animals (**Mastigophora**), occurring singly or in groups of two or four. Occurs in sponges, where the action of flagella of many **choanocytes** draws currents of water into the body.

In typical structure the flagellum has a delicate axial filament arising from a **blepharoplast** in the cell and surrounded by a sheath of protoplasm except at its tip. In many cases there is also a larger parabasal body connected by fibrils with the axial filament and with the nucleus. The flagellum is much larger than a cilium and moves in undulations.

2. The whip-like terminal portion of the antenna of a **crustacean.** (A.W.L.)

FLAME. **Ignition.**

FLAME CELL. **Excretory System.**

FLAME CUTTING. Cutting of ferrous metals by oxidation, using a stream of oxygen from a blowpipe or torch. The metal is preheated to a bright red, approximately 1500° F., by fuel gas jets in the cutting torch. The stream of oxygen is then applied through a central jet. Once oxidation of iron to Fe_3O_4 begins, the heat of the reaction plays a large part in the continuation of the process. Approximately 30% of the molten metal is removed without actual oxidation by the mechanical washing action of the stream of gas and burnt metal. The preheating gases are oxy-acetylene, hydrogen, natural gas, city gas, etc.

The oxygen lance is a form of flame cutting in which oxygen, supplied through an iron pipe, is the only fuel used. It is used for heavy-duty cutting.

Very heavy sections may be cut with the blow torch. Close dimensional tolerances can be maintained, using machine operated torches, thus flame cutting has become a production tool as well as a means of salvaging scrap. Underwater flame cutting is possible at depths of 135′ or more using special practice. (R.H.H.)

FLAME HARDENING. Surface hardening of steel or cast iron by heating a thin surface layer to the hardening temperature with an oxy-acetylene flame, followed by rapid cooling. Depending on the nature of the part to be hardened, either the torch system or the work itself may be moved. Cylindrical parts are rotated before a stationary flame. An air jet or liquid spray following the torch is used to quench-harden the surface. The relatively cool metal in the interior hastens cooling of the surface by conduction. The depth of flame hardening may be less than 1/16″ to about 1/4″ depending on the thickness of the section and the service requirements. Distortion is generally less than in parts hardened by general heating and quenching.

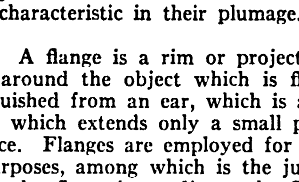
Since no hardening agent such as carbon or nitrogen is added to the surface of the steel by this process, only steels having sufficient carbon to harden readily upon quenching are used for flame hardening. The most desirable range is 0.35–0.70% carbon. The hardening treatment is followed by a low-temperature tempering treatment to relieve quenching strains. Typical applications of flame hardening are gear teeth, cams, bearing surfaces, rail ends, crankshafts, and many other machine parts and tools. (R.H.H.)

FLAMINGO. Aves, Ciconiiformes. Large wading birds (**Aves**) of several species found in the warm regions of the world with the exception of Australia. They have very long legs and neck and a broad beak bent sharply downward at the middle. Red or rosy shades are characteristic in their plumage. (A.W.L.)

FLANGE. A flange is a rim or projection extending completely around the object which is flanged. Thus it is distinguished from an ear, which is a similar projection, but which extends only a small portion of the circumference. Flanges are employed for a great many different purposes, among which is the juncture of adjacent shafts by flanged **couplings,** the flanges providing area through which connecting bolts may be passed. Flanged wheels are commonly used to maintain the position of a wheel and axle group upon parallel rails; pipe flanges, for the connection of **pipes** which are not to be screwed together.

Low-pressure piping larger than 6-in. and high-pressure piping are, in the majority of cases, connected by companion flanges. Flanges are drilled to a standard templet and drawn tightly together by means of flange bolts. Alloy steel bolting to conform to A S T.M. specifications should be used when pressures exceed 160 lbs. per sq. in. or temperatures exceed 450° F., but below these limits commercial bolting should be used.

Flanges are made of cast iron, cast steel, forged and rolled steel. The face of the joint is always machined smooth. The Van Stone joint has proved to be a satisfactory connection and is widely used. For the most severe service the lap is made full pipe thickness with



Loose flange (Van Stone) pipe joint.

a perfectly smooth finish to the laps. The flanges are loose on the pipe and the laps are clamped between them. The outside diameter and minimum thickness of pipe flanges are the same as those for fittings.

For the structural engineering significance of flange see **Bridge, Girder, I-Beam.** (F.T.M)

FLAP. **High Lift Devices.**

FLASH. **Forging.**

FLASH POINT. The lowest temperature at which an oil will decompose to an inflammable gaseous mixture, demonstrable through its explosive quality, is its flash point. The flash point occurs at a temperature lower than the burning point, which is the lowest tem-

perature at which the production of combustible gas occurs rapidly enough to support a steady flame. The flash point is an important characteristic of oils used for lubricating bearings, since any heating to the flash point would result in decomposition of the oil as a lubricant. On the other hand, the flash temperature is less important than the burning temperature in determining the fire risk of an oil. The flash point is tested experimentally by heating the oil under certain specified conditions in a cup. A thermometer is suspended in the oil so that the temperature may be read during the test. Periodically an open test flame is introduced through an opening in the cover to detect the slight explosive puff which follows when the flash point has been reached. (F.T.M.)

FLASH SPECTRUM. At the instant of second or third contact during a total solar **eclipse** the edge of the moon is tangent to the **photosphere** of the sun as shown in Fig. 1. With the photosphere covered, the highly heated atmosphere of the sun, known as the **reversing layer** and the **chromosphere,** flashes into view. With the photosphere covered the continuous spectrum of the sun is cut off and the bright-line **spectrum** radiated by the atmosphere may be observed.

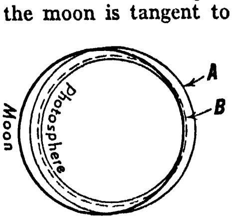


Fig. 1. Flash spectrum.

If a photograph is taken with an **objective prism** at the instant of second or third contact, a series of curved images of the atmosphere of the sun will be obtained, each in one particular radiation. As indicated by Fig. 1, radiations due to elements at the highest levels, as at *A*, will give longer curves than the radiations due to elements at lower levels such as *B*. Such a bright-line spectrum is referred to as a flash spectrum, since it is only visible for a few seconds at the instants of the contacts.

Fig. 2 shows a section of a flash-spectrum plate. The long curved lines are due to the so-called *H* and

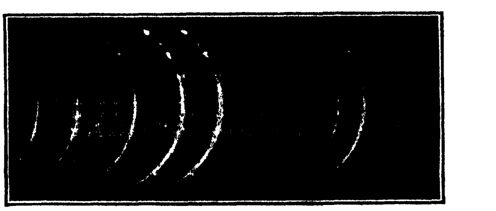

Fig. 2. The flash spectrum. Photographed by J. A. Anderson near the end of the total eclipse of January 24, 1925. (*Mount Wilson Observatory.*)

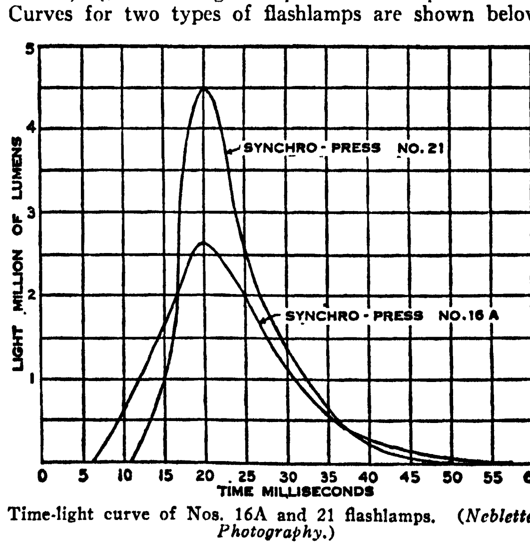
K lines of calcium and their extreme length indicates that this element rises to the very top of the chromosphere. The projections from the curves are due to prominences, and the breaks in the curves are caused by irregularities on the moon. Other lines, of shorter length, are due to elements in the lower regions of the solar atmosphere. A careful study of flash-spectrum plates gives the distribution of elements throughout the solar atmosphere. Such results are of great value for a variety of problems of solar research, such as the selection of radiations to be used with the **spectroheliograph** for obtaining photographs of the sun at different levels. (W.K.G.)

FLASHING, STRUCTURAL. Flashing is a method of sealing joints on buildings, especially around roofs, chimneys, gutters, and valleys, in order to render them water-tight. The method consists of using strips, or shingles, of flashing material which are worked into the normal roof surface and turned over the joint. Where the flashing turns up, as along a brick wall, it is necessary to counter-flash, that is to let a strip of flashing material into the brickwork and bend it down over the other flashing. A sloped shingle **roof** flashed against a brick wall requires flashing shingles which are worked under the top course of the regular shingles and turned up along the bricks. Corresponding counter-flashing let into the brick is bent down over these flashing shingles. A joint between the gutter and cornice is made weatherproof by flashing. Usually the flashing extends from under the lowermost course of shingles and is turned down over the edge of the gutter. The most common flashing materials are tin-coated sheet iron and copper. Lead and zinc are used to a limited extent. (F.T.M.)

FLASHING, THERMAL. Liquids may exist with thermal stability at high temperatures provided they are subjected to sufficiently high pressure. Water, for example, may be heated to about 700° F. without boiling if under a pressure of 3200 lbs. per sq. in. It is true of liquids in general that the lower the pressure on them the lower the boiling temperature and the lower the heat contained in the "saturated" liquid. Thus high-temperature liquids when passed from a region of pressure sufficient for stability into a low-pressure region are not able to contain all the heat originally possessed as heat of fluid, and will be spontaneously partially evaporated by the surplus. This violent readjustment to thermal equilibrium is called "flashing," and is a common occurrence, having many uses (see **Deaerator** and **Evaporator**), and occasionally creating hazards. For example, the destructiveness of a boiler explosion arises mainly from the violence of flashing action since the water originally contained in a ruptured boiler drum at 600 lbs. per sq. in. pressure suffers an almost instantaneous *four hundred fold* expansion in volume. (F.T.M.)

FLASHLAMPS. The photoflash lamp, developed about 1930, has completely replaced the older magnesium lamp and flashlight powder. The lamp consists of a globe of heat-resistant glass enclosing a low-temperature filament and finely drawn aluminum wire in an atmosphere of oxygen. When an electric current of 6 volts, or greater, is applied, the filament is heated to incandescence and ignites the wire, producing a brilliant flash. The duration and intensity of the flash vary with the size of the lamp, the amount and size of wire it contains, and the gas pressure.

The characteristics of a flashlamp are usually represented by time-intensity curves in which the time elapsing from the application of the electric current to the end of the flash is plotted in milliseconds (1/1000 second) against the light output of the lamp in lumens. Curves for two types of flashlamps are shown below.



Time-light curve of Nos. 16A and 21 flashlamps. (*Neblette's Photography.*)

Flashlamps are ordinarily used with a synchronizer which is a device for synchronizing the flash of the lamp with the opening of the camera shutter. Since the blades of the modern lens shutter require approximately 5 milliseconds to open to full aperture, while most flashlamps require from 15–20 milliseconds to reach peak intensity, the synchronizer must delay the tripping of the shutter by 10–15 milliseconds after the electrical circuit of the lamp is closed. This allows the flash of the lamp to reach full intensity before the shutter opens for the exposure. This is accomplished in some synchronizers by a mechanical delaying gear and in electro-magnetic synchronizers by the use of a solenoid with an adjustable air gap in the shutter circuit. This air gap is adjusted so that from 10–15 milliseconds will elapse before the charge on the solenoid is sufficient to pull down the lever which trips the shutter. (C.B.N.)

FLAT HEAD. **Pressure Vessels.**

FLATFISH. Pisces, Teleostei. Fishes (**Pisces**) which lie on one side of the body when adult. The head is modified so that both eyes are on the upper side. Many species are valuable food fishes and the halibut is an important source of vitamin-bearing oil now widely used in place of cod-liver oil.

The flatfishes make up the family Pleuronectidae. Among the included species are the **halibut, plaice, flounder, turbot, brill, soles,** and **dabs.** (A.W.L.)

FLAT-PLATE AREA, EQUIVALENT. That area of an imaginary flat-plate, normal to an air stream, whose drag would be the same as that of an actual body at the same air speed is the equivalent flat-plate area of the body. The coefficient of drag of a flat-plate is known to vary with the **aspect ratio** and the area, but it is frequently assumed as 1.28. However, as the area is an imaginary one at all events, the drag coefficient may as well be assumed equal to 1. It is seen that equivalent flat-plate area might have two values, f and f', which are related thus: $f = 1.28f'$.

If D = drag, lbs., of a body in air stream of **dynamic pressure** q,

$$f = \frac{D}{q}$$

$$f' = \frac{D}{1.28q}$$

(F.T.M.)

FLATWORM. **Platyhelminthes.**

FLAX. *Linum usitatissimum.* Linaceae. Flax is the name given to the pericycle fibers of *Linum usitatissimum,* a plant native to Europe. (For a discussion of New Zealand flax, *Phormium tenax,* see the next article.) They were probably the first vegetable fibers to be used by man. Picture-writings at Thebes not only show the plant, but also give details of the processes used in making cloth from the fibers. Egyptians, Greeks, ancient Hebrews, and Romans knew the fiber and used it. Mummy-cloths are often of linen.

The flax plant is a slender annual attaining four feet in height and branching slightly. It has small **lanceolate** leaves and clear blue flowers. When mature it bears seed capsules containing ten seeds each and about ¼″ in diameter. Successful cultivation demands an abundance of **potassium** and **phosphorus** in the soil and plenty of moisture. The plant is cultivated not only for the fibers, but also for oil. The best fibers are obtained from plants grown in cool regions, while the best oil is derived from plants grown in tropical countries like India.

For preparing flax, the plants are pulled or cut before they are mature, and stripped of all leaves and seed capsules. The denuded stems are then tied in small bunches and immersed either in stagnant or slowly running soft water, where they are left for several days. During this time, the stems are attacked by **bacteria,** which bring about fermentation, causing a breaking down of the woody tissues and a partial separation of cells due to the action of the bacterial **enzymes** on the pectic substances binding the cells together. This process is called "retting." Sometimes the flax stems are spread on the ground in a thin layer and left exposed to the action of dew and sunshine for a few weeks. The same result is obtained, the process being now called "dew-retting." The retted stems are removed from the water, washed and cleaned of as much non-fibrous material as possible. This process is known a "Scutching." "Hackling" follows, and is a sort of combing which removes any remaining non-fibrous material. The fibers thus obtained are in reality bundles of cells which occurred as pericycle fibers in the stem. Good fibers vary from 12–36″ in length, while many shorter ones are obtained. Short and tangled fibers are called "tow." The fibers vary in color from yellowish to dirty gray, largely depending on the attention paid to the retting process. They are soft and flexible, capable of division into smaller bundles of fewer cells. They are very strong, each cell possessing a uniformly thick wall which surrounds the very slender central cavity or lumen.

The principal use of the fibers is in the manufacture of thread requiring great strength, such as shoe thread, bookbinding thread, fish line and fish-net twine, and also in the making of fine cloth such as table-linen and handkerchief linen. All cloth made from flax fibers is called linen. Flax fibers conduct heat much more rapidly than cotton and so cloth made from them is cooler and much favored in tropical countries.

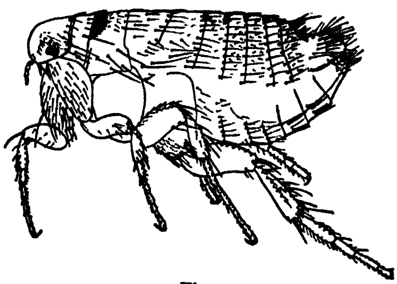
In addition to the fibers, flax plants yield a valuable oil, called linseed oil. (See **Fixed Oils; Esters.**) In making this the seeds are crushed by machinery, heated to 165° F. and treated with naphtha which extracts the oil. The seeds are about 40% oil. This oil, a drying oil, is used in the manufacture of paints, varnishes, and patent leather, as well as in making linoleum and oilcloth.

The oil cake left after the oil is pressed from the seeds is used directly as a cattle food or is ground up into oil meal and used for the same purpose. (R.M.W.)

FLAX, NEW ZEALAND. *Phormium tenax.* Liliaceae. (For a discussion of common flax, *Linum usitatissimum,* see preceding article.) The fibers of New Zealand flax occur as **sclerenchyma** sheaths surrounding the vascular bundles in the long, straight, rather stiff leaves of this plant. The plant, a native of New Zealand, has been introduced into Australia and other countries. In the United States, it is cultivated to some extent, often as an ornamental plant. The leaves, from 4–8′ long and up to 8″ wide, may be 20% fibrous material. To obtain the fiber the leaves are cut off and scraped to remove much of the non-fibrous material After this the fibers are combed out and cleaned. They are very white, soft, flexible, lustrous and tough. They may be 5′ long. The principal use of New Zealand flax is for binder twine, baling rope, and cordage, often in combination with sisal or other fibers. A fine cloth resembling linen duck can be woven from it. From 3000 to 5000 tons of this fiber are imported into the United States annually. (B.S.M.)

FLEA. Insecta, Siphonaptera. Small **insects** with transversely compressed bodies, sucking mouths, and no wings. They live as parasites in the adult stage on the bodies of mammals and more rarely on birds. The larvae have biting mouths and eat fragments of organic matter in the debris about the sleeping places of the hosts; they are never parasitic.

Pyrethrum powder is an effective deterrent for these pests. It can be dusted into the fur of dogs and cats



Flea.

and used about the house in regions where fleas are troublesome to man himself. (A.W.L.)

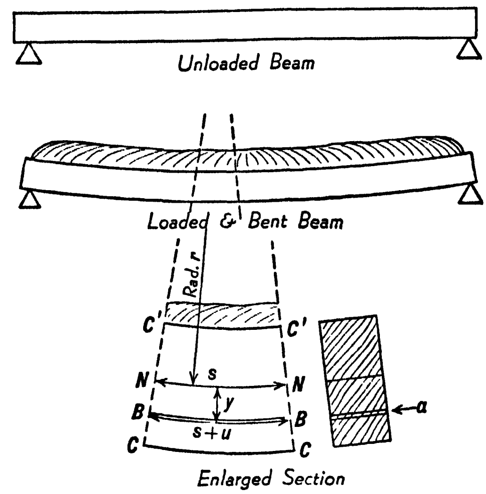
FLEXIBLE COUPLING. Coupling.

FLEXURE. Flexure is a term which is used to denote the curved or bent state of a loaded beam. A horizontally located **beam**, transversely loaded with vertically directed load, offers an example of load-carrying ability derived through flexure. In flexure, an elastic structural material undergoes a deflection sufficient to set up in its material stresses which will support the load. Deflection under load is an essential and necessary part of the process of load carrying by a beam, for until the deflection has occurred, there are set up in the beam no resisting forces. Thus if an unloaded beam is perfectly straight and horizontal, it must assume a slightly curved position if any external loaded is supported by it. The only way in which a loaded beam could be straight would be to have had an initial deflection in a direction opposite to the loading.

The so-called flexure theory establishes a relation between the fiber stresses at any point in a beam and the bending moment causing these stresses. This theory is based on two fundamental assumptions whose validity, within ordinary working limits, has been established by experiment. The first assumption is that a cross-section which was a plane before bending remains a plane after bending. This implies that the unit deformations are proportional to the distance from the neutral axis. The second assumption is that the fiber stresses are proportional to the deformations resulting from these stresses. If a **tension** member is subjected to an axial load in a testing machine it will be found that, for stresses below the **proportional limit**, the ratio of the unit stress to the unit deformation is a constant called the modulus of elasticity. This would also be true if the test specimen were a short compression member. In order to reconcile the second assumption it must be further assumed that the fibers act similar to test specimens and that the modulus of elasticity is the same for tension and compression.

It will now be shown how deflection and load-carrying ability are interrelated in a beam. First, it will be assumed that the structural material is elastic, that is, within the elastic limit the stress is proportional to the strain inducing it, and that it is a homogeneous material. The results produced by materials not exactly meeting these specifications are usually in good accord with the theory based on these assumptions.

Assume that there is a beam of rectangular cross-section mounted horizontally between simple supports. If one were further to assume this material is weightless, the axis of the beam would be absolutely horizontal. Next a gravity load is placed on the beam, resulting in a certain deflection which sets up resisting couples within the beam, enabling it to carry the load. It must be evident that after a static condition is reached, the **external bending moment** thus imposed on the beam must, at any point, be balanced by an internal moment arising out of the stresses in the material of the beam. (Next consider the enlarged section of the bent beam.) If the section is taken sufficiently small, it can be as-



sumed to be bent in the arc of a circle whose radius is r. The upper fibers, i.e., $C'C'$, are naturally compressed or shortened in length, and the lower, CC, are stretched. At some intermediate plane, NN, there must exist an unstretched fiber whose length is the same as it possessed in the unloaded state. This axis of no strain is called the neutral axis. If its length is s, then the length of a typical fiber such as BB, located at a distance y from the neutral axis, is $s + u$, in which u represents the stretch $\frac{u}{s}$ is the percentage stretch, or strain, of the material. From the geometry of the figure it is apparent that the strain $\frac{u}{s} = \frac{y}{r}$. Since stress is proportional to strain, the factor of proportionality being the modulus of elasticity E, it follows that the stress on $BB = p = E/\frac{y}{r}$. Referring to the cross-section of this small element of the beam, the end area of fiber BB is taken as a. The stress p acting on this area produces an elementary internal force ap. Above the neutral axis there are similarly produced forces, but oppositely directed. The sum of all these longitudinal forces is, of course, zero, since the beam is static; however, at any cross-section they produce, *in toto*, a torque or moment around the neutral axis which is exactly equal to the external bending moment at that section. For example, the moment of the force acting on the fiber BB is apy about the neutral axis. The total moment, then, is the Σapy about the neutral axis.

Substituting $\frac{Ey}{r}$ for p, the total moment equals

$$\frac{E}{r}\int ay^2 = \frac{E}{r}I.$$

The last step shows how the **moment of inertia** enters into the flexure formula. Since r is not a convenient quantity to work with, a substitution of $\frac{p}{y}$ is made for $\frac{E}{r}$ resulting in the common flexure formula:

$$M = \frac{pI}{y}.$$

In this formula, M is the bending moment at a section where the moment of inertia is I, and p is the unit stress at y distance from the neutral axis.

It is readily shown that the neutral axis is coincident with the center of gravity of the cross-section of the beam From above, we extract the following equation:

$$ap = \frac{E}{r} ay$$

$$\int ap = \frac{E}{r} \int ay.$$

$\int ap$ is the total force within the beam parallel to the neutral axis, and is zero, as explained above, but this results also in $\int ay$ being equal to zero, which can be true only when the distance y is a moment arm around the center of gravity of the cross-sectional area.

The flexure formula is valid as long as the stresses are within the proportional limit. In the derivation of this formula it is assumed that the horizontal stresses are the only internal forces which resist the external bending. As a matter of fact, the true maximum tensile or compressive unit stress, called a principal stress, is the **resultant** of the bending and the shearing stress acting at the point. But, as has been previously stated, the stresses which are obtained by the flexure formula are reasonably correct for ordinary design purposes. (C.W.C., F.T.M.)

FLICKER. Aves, Piciformes. Moderately large **woodpeckers** of North America which differ from the other woodpeckers in feeding habits. Flickers eat many insects on the surface of the ground and are particularly fond of ants, which they catch on the long sticky tongue. Three species are recognized, the common or yellow-shafted flicker, *Colaptes auratus,* the red-shafted *C. cafer,* and the gilded flicker, *C. chrysoides,* of the southwest. The common flicker is sometimes called the high-hole.

Other species of the same genus occur in South America. (A.W.L.)

FLICKER PHOTOMETER. **Bench Photometers.**

FLIGHT. Locomotion through the air. Some animals travel through the air for short distances by gliding, supported by broad expansions of various parts of the body, but in true flight the animal is able also to support and propel itself by muscular activity. True flight occurs only in the insects, birds and bats. The pterodactyls, an extinct group of reptiles, were also able to fly.

The gliding animals include the **flying fishes,** an **amphibian** (the flying frog), a **reptile** (the flying dragon); and several species of mammals (**flying squirrels, flying lemur**). With the exception of the flying fishes all are provided with broadly expanded thin structures on which they coast down the air from one place to another. The supporting structures of the frog are enormous webbed feet, those of the dragon are broad membranes along the sides of the body supported by elongate ribs, and those of the flying lemur and flying squirrels are folds of skin along the sides of the body between the fore and hind legs. Flying fishes are supported during long leaps through the air by the greatly enlarged pectoral fins.

True flight also depends partly on the possession of broad light planes, the **wings.** These organs are moved by special muscles in such a way that their pressure against the surrounding air lifts and propels the body. Flight demands relatively great expenditure of energy, hence the flight muscles are highly developed. In the most rapid and powerful fliers this is especially true; the wings are smaller and the muscles larger in contrast with the broad wings and relatively smaller muscles of weaker fliers.

In the birds flight is accompanied by accessory adaptations for securing large amounts of oxygen, for storing energy in abundance, and to provide rigid skeletal support against the stresses of flight. The feathers are an insulating coat of high efficiency in the cold upper air. Birds are, in fact, primarily adapted for flight and in other respects conform to the limitations imposed by this adaptation. Only by such extensive adjustment to life in the air are they able to remain on the wing for many hours without rest, like the albatrosses during their everyday life and like many other birds during migration. The flight of birds, moreover, is the most rapid locomotion of living things, rivaling even the mechanical transportation achieved by man. Birds commonly fly 30 or 40 m.p.h. and speeds in excess of 100 m.p.h. have been recorded.

Some birds are adept at soaring, a type of flight in which the wings are held extended and the bird depends on air currents to carry it. It may ride ascending currents to high levels and may always glide to lower levels, moving only to maintain its equilibrium. The vultures very commonly fly in this way for long periods without flapping a wing.

Since the air is too light for an animal to float in it, all flying things must also have some other means of locomotion. The single known exception is a South American May fly. Although this insect walks beneath the water as a **larva,** during its adult life its legs are vestigial. When it once emerges from the water it must fly until the brief remainder of its life is ended, and when it once drops to the water or to the ground it never rises again. (A.W.L.)

FLIGHT, ARTIFICIAL AERIAL. The act or action of passing through the air is flight. The word is also used collectively to describe the like motion of multiple objects in flight. Thus, a *flight* of arrows. The act of flight is the exercise of ability to overcome the forces of gravitation and pass through the air, as by use of wings, while the action is descriptive of a journey through the air from one point to another. Natural flight is performed by the birds, mechanical flight by man-made devices—airplanes, helicopters, and ornithopters. Powered airships make flights; however, the flight of a free or captive balloon is better described as an *ascension.*

The science of flight and the machines employed to secure it are covered in many of the aeronautical articles of this volume. However, it may not be amiss to review, briefly, the history of flight. Mankind has apparently always been interested in flight. Probably from the first the natural flight of birds and the advantages of such travel inspired him with a desire to emulate this means of transportation. In ancient mythology there are many stories associated with the supposed flight of men in emulation of the birds. One of the better known of these legends is the legend of Icarus, the Greek, who essayed to escape from prison by fastening feathers to his body with wax. Unfortunately, he flew so near the sun that the wax was melted and Icarus plunged downward into the sea. Legendary horses have borne wings, and in the *Arabian Nights* Sinbad maneuvered some flights with the aid of the great roc. It took many centuries to take flight out of mythology into concrete proposals as to how it might actually be accomplished, and still more centuries went by before the mechanical flight of a man-carrying machine was a reality. For several centuries early in the Christian era there was little progress, but as scientists, inventors, and experimenters ventured farther along the road to artificial flight, progress accelerated. After 1910 the rate of progress was enormous, and men everywhere made great strides in pushing back the frontiers of flight in every direction.

With no thought of mentioning all the brave and gifted men who have given their efforts, and sometimes their lives, to advance man nearer to mechanical flight, a chronology of significant events and historical flights is presented.

1485 (approx.)..	Leonardo da Vinci	Research on the possibility of flight. Flying models built. Invention of the propeller.
1655..........	Robert Hook	Scientific evaluation of the possibility of flight.
1783..........	Joseph and Jacques Montgolfier	First hot-air balloon ascension.
	Pilâtre de Rozier, Marquis d'Arlandes	First free balloon ascension, man-carrying.
	Jacques Charles	Man-carrying ascension by hydrogen balloon.
1797....... .	Andre Garnerin	The first successful parachute descent.
1810....	George Cayley	Scientific analysis of the principles of flight. Built successful man-carrying glider.
1836..........	Charles Green	500-mile free balloon flight from London to Weilburg, Germany.
1842..........	William Henson	Designed a steam-powered monoplane of excellent possibilities. A full-scale machine was never built.
1852..........	Henri Giffard	Built and flew steam-engine powered, non-rigid airship capable of being navigated in light winds.
1872..........	Paul Haenlein	Built and flew semi-rigid airship with internal combustion engine power.
1889..........	Otto Lilienthal	Built several man-carrying gliders and made several hundred glider flights. Wrote a book summarizing his observations and experiments in aerodynamics.
1891..........	Octave Chanute	Conducted glider experiments, and wrote on the subject of aviation, in particular, stability.
1896–1899.....	Percy Pilcher	Made several hundred flights in a glider of his own design.
1896–1903.....	Samuel Langley	Scientific study of heavier-than-air flight, culminating in the building of powered models, about the success of which controversy raged for several years.
1898–1910.....	Alberto Santos Dumont	Built successful airships and airplanes which he himself flew.
1903..........	Wilbur Wright, Orville Wright	Built and flew an internal combustion engine powered biplane. The flight on December 17th is generally accepted as the first successful flight of a powered airplane.
1907..........	Walter Wellman	Pioneered in the use of dirigible for explorations.
	Gabriel Voisin, Charles Voisin	Foremost early builders of airplanes in France.
1909..........	Louis Bleriot	Flew the English Channel in a monoplane of his own design.
	Glenn Curtiss	Built and flew a biplane, winning the Gordon Bennett Trophy race at 46 m.p.h.
1910..........	Charles Hamilton	Won the New York *Times*-Philadelphia Public *Ledger* prize with a round-trip flight between New York and Philadelphia.
	Claude Graham-White	Piloting a Bleriot monoplane, won the Gordon Bennett race with an average speed of 61 m.p.h.
	Eugene Ely	Made the first take-off from a ship.
1910–1915.....	Lincoln Beachey	Pioneer acrobatic pilot.
1911..........	Earl Ovington	Piloted first official airmail plane in the United States.
	Harriet Quimby	First woman pilot in the United States.
1913..........	Igor Sikorsky	Pioneered in the construction of multi-engined planes.
1914....	Count von Zeppelin	Constructed long-range dirigible airships.
1919..........		U. S. Navy NC-4 seaplanes cross the Atlantic.
	John Alcock, Arthur Whitten-Brown	First non-stop trans-Atlantic flight from Newfoundland to Ireland.
1920..........	Rudolph Schroeder	Piloted an airplane to over 30,000′ altitude.
1923–1933.....		Series of disasters to large dirigible airships diverted attention to heavier-than-air aircraft.
1923..........	John A. Macready, Oakley Kelley	Made the first non-stop East-West transcontinental flight over the United States.
	Juan de la Cierva	Developed the autogyro, first practical rotating-wing aircraft.
1925..........	Lincoln Ellsworth	Pioneered in Arctic and Antarctic explorations by air.
1926..........	Richard Byrd	Pioneered in Arctic exploration by air.
	Roald Amundsen	Arctic explorations by dirigible.
1927.	Charles Lindbergh	Made famous non-stop flight from New York to Paris in the "Spirit of St. Louis," a Ryan monoplane.
	Clarence Chamberlin, Charles Levine	Made non-stop flight from New York to Eisleben, Germany, in Bellanca monoplane.
	Lester Maitland, Albert Hegenberger	First to complete a non-stop flight from the continental United States to Hawaii.
1928..........	Charles Kingsford-Smith, Charles Ulm	Flew the first Pacific crossing from the United States to Australia in a Fokker tri-motored monoplane.
	Charles Collyer, John Mears	First circumnavigated the globe by air, with a Fairchild monoplane.
1929..........	Ira Eaker, Carl Spaatz	Established refueling record of 150 hours, 40 minutes.
	James Doolittle	Pioneered in blind-flying technique; also, holder of several notable speed records.
	Richard Byrd	Pioneered in Antarctic exploration by air.
1931..........	Auguste Piccard, Charles Kipfer	Stratosphere balloon ascension to 52,000′.
1933..........	Wiley Post	Solo circumnavigation of the earth in less than 8 days.

1936	Hugo Eckener	Commanded the dirigible airship Hindenburg on several commercial trans-Atlantic flights.
		Radio range airway well established in the United States.
1937	Igor Sikorsky	Built commercially successful helicopter.
1938	Howard Hughes	Circumnavigated the earth in less than 100 hours.
1939		Russian pilots complete non-stop flight from Moscow to Vancouver across the North Pole; Russian pilots complete non-stop flight from Moscow to California, 6262 miles.
		Regularly scheduled trans-Atlantic airline flights begun; air-cooled engines reached 2000 hp. size.
1940		Scheduled airline flights across the Pacific inaugurated; first all-blind instrument flight between termini; S. Campini, first jet-propelled airplane, a Caproni; high-altitude (24,000') pressurized-cabin commercial airliner introduced; airlines of U. S. operate 12 months without fatality; U. S. Federal Airways System developed; popularity of private flying soars in U. S.; insurance rates drop; colleges adopt aviation courses.
1941	F. Whittle	Developed successful jet-propelled plane; the RAF is credited with saving England from German invasion; Japanese air arm attacks U. S. base at Pearl Harbor; commercial stratoliner operations begin; air pick-up service developed; tailless aircraft again appear; mass production of military airplanes; commercial air flights on radio direction finders; airliners with 285 m.p.h. speed, capable of carrying 60 passengers 5000 miles appear.
1942		Air force strength proves dominant military factor; Japanese aircraft sink British battleships "Repulse" and "Prince of Wales" off Singapore; pre-flight training introduced into U. S. secondary school curricula; four-engined Fortress in mass production; thousand-bomber air raids become a reality; battle of Midway fought and won by U. S. Naval air arm; jet-propulsion plane developed in the U. S.; first 70-ton flying boat—"Mars."
1943		Four-engined Superfortress in mass production; allies attain air supremacy on nine war fronts; U. S. AAF grows to 44 times its 1940 strength; precision bombing introduced; air and seapower coordination stops Japanese; women pilots join men on dangerous missions; civil air patrol successful in anti-submarine operations.
1944		West-east record flight across U. S. by "Constellation," non-stop, in less than 7 hours; jet-propelled fighters appear in combat; resonance ducts used to power flying bombs; long-range liquid-fuel rocket used as a war missile; external wing tanks used to extend range of fighter planes.
1945	J. K. Newman, R. K. Smith	Mosquito bomber flight from England to India, 4700 miles in 12 hours, 25 minutes, average 378 m p h.
	E. W. Leach	American altitude record of over 9 miles in jet-propelled plane announced as having been attained in 1943 by Bell Aircraft Corp.
	J. R. H. Merfield	Mosquito bomber from Newfoundland to England, 2500 miles in 5 hours, 10 minutes, average 455 m p.h.
	F. A. Armstrong	Four B-29s from Japan to Washington, D. C., 6544 miles lead plane's time, 27 hours, 29 minutes.
	H. J. Wilson	Jet plane 611 m p.h. top, 606 m.p.h. average, off Herne, England.
	J. R. Holzopple	A-26 around the world, 24,859 miles, 96 hours, 50 minutes flying time; extensive prior use of radar in aerial navigation revealed; U. S. AAF operates on 5 air fronts; air transport system spans the world; fighter plane speeds increased to 500 m.p.h.; airpower credited with major role in defeat of Germany and Japan.
1946		War-developed B-29 sets new record, carries 5000-kg. payload at 366 m p h. over a 2000-km. course; helicopter duration performance set at new high of 9 hours, 33 minutes, 27 seconds by a Sikorsky R-5; Lockheed P-80 sets speed record of 495 m.p.h. on a 62-mile low-level run; helicopter distance record set from Wright Field, Ohio, to Boston, Massachusetts, time 10 hours, 3 minutes; helicopter speed record brought from 76 m.p.h. to 110.5 m.p.h. by Sikorsky 5-A; airplanes flying 6 miles high used as experimental television relay points.

(F.T M.)

FLINT. Flint is a rock composed essentially of a cryptocrystalline form of silica. It is very dense and tough, breaking with a **conchoidal** fracture; colors, usually dark grays, blues, or browns, often black. It occurs chiefly as nodules and masses in **chalks** and **limestones.** Flint is particularly interesting because it was used by primitive man for making instruments (artifacts) for thousands of years before he learned to use bone and metal. Flint still remained an essential mineral resource for making fire, including the flint locks on guns, until the close of the 18th century. From the dawn of civilization the best flint has come from Belgium and the coastal chalks of the British Channel and the Paris Basin. (R.M.F.)

FLINTY CRUSH-ROCK. A term proposed by the Scottish geologist Clough for the almost structureless, flinty portion of **mylonite,** an extreme product of dynamic **metamorphism.** (R.M.F.)

FLIPPER. An appendage of the aquatic **mammals** in which the digits are enveloped by continuous tissue so that the entire structure forms a flat paddle for swimming. Flippers occur in **seals, manatees, whales,** and related forms. (A.W.L.)

FLOAT, AIRPLANE. Seaplane.

FLOATING FOUNDATION. Foundation.

FLOCCULI. Sun.

FLOOD PLAIN. The relatively level surface, or surfaces, within a river valley, caused by the depositional work of the river, especially during flood or high-water. Compare and contrast with the **tapset** beds of **delta.** (R.M.F.)

FLOODING. Gas Absorption.

FLOOR BEAM. A **beam** which is the direct support of the floor **load** of a building and transfers this load to the adjacent girders or columns is a floor beam or floor joist. These beams may be of wood or steel

The term floor beam is also used to designate the transverse beams of the floor system of a **bridge** which transmit load to the longitudinal **girders** or **trusses.** (C.W.C.)

FLORET. A small flower; for example, one of the flowers forming the head of the plants of the **Composite Family.** (R.M.W.)

FLORICAN. Bustard.

FLOTATION. Classification.

FLOUNDER. Flatfish.

FLOUR. Wheat.

FLOW. Fluid Flow.

FLOW, LAMINAR. A fluid is said to have laminar flow if the mass of flow may be considered as advancing in separate laminae with simple shear existing at the surface of contact of the laminae should there be any difference in mean speed of the separate lamina. If turbulence exists, its effect is confined to a lamina and there is no exchange of momentum between laminae. (F.T.M.)

FLOW LINES. Macrostructure.

FLOW METER. The flow of a fluid (see **Fluid Flow**) is one of the more difficult physical quantities to measure, especially if the fluid is a gas, and yet there often arises the necessity or desirability of measuring the flow of a vapor, liquid, or gas. Several meters have been developed for measuring these quantities. In distinguishing a flow meter from a quantity meter, flow is a quantity passing a given section of the conduit per unit of time: thus gal. per min. of water, cu. ft. per min. of gas, and lbs. per min. of steam, are flows. One of the most common principles employed in a flow meter is that of the interchangeability of pressure and velocity head of a fluid. Fundamental hydrodynamic theory indicates pressure, expressed as head of a fluid, and velocity to be interchangeable in the ratio as expressed by

$$v = \sqrt{2gh}.$$

The Venturi meter is used in the application of this principle to fluids. It is shown in Fig. 1. The instrument is

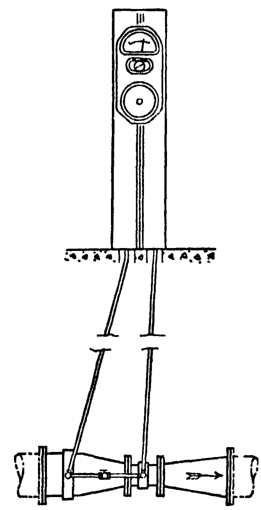


Fig. 1. *(Builders' Iron Foundry.)*

essentially a manometer device calibrated to read flow in cu. ft. per sec., gal. per min., etc. Recording and registering features may be added to the indicating meter. The Venturi meter principle is based on the reduction of pressure accompanying increase of velocity. (**Bernoulli's** principle.) The velocity is increased by inserting a fitting in the pipe line which converges to a minimum section and then diverges to the normal pipe size. Pressure leads are brought from the low-pressure region and from the normal-pressure region to the manometer of the instrument. The theory of the Venturi meter will be found in all standard works on hydraulics. The theory yields the equation

$$H = \frac{8Q^2}{\pi^2 g d^4}\left[\frac{d^4}{d_1^4} - 1\right],$$

in which H is the ft. of water of differential head produced by a flow of Q cu. ft. per sec. The internal diameter of the pipe is d, of the minimum section, d_1. The actual discharge Q will be from 0.96 to 0.99 of the theoretical Q. The above equation shows that when the dimensions of the Venturi throat fitting have been fixed, the flow can be measured proportional to the square root of the differential head H.

This does not exhaust the list of apparatus devised to measure flow of liquids. For example, **weirs, weighing** tanks (in conjunction with a chronometer), and displacement-type meters will measure flow.

Lighter fluids, such as air or steam, are measured in meters of the orifice type. This is explained in connection with Fig. 2. A constriction of flow produced by an orifice in a metal disk inserted between pipe flanges creates a differential head that is proportional to the square of the flow. This pressure head is taken off

through two small pipe connections and transmitted to a mercury U-tube in one leg of which are a large number of graded-length contact rods connected to resistances.

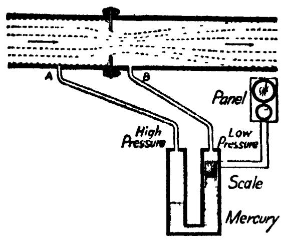

Fig. 2. Republic electric flow meter.

A flow of steam causes a certain pressure head on the manometer and a corresponding rise of the mercury level in the contact rod chamber. The rise of mercury cuts out a definite amount of resistance, depending on the steam flow. The meter itself is an electrical instrument which measures the varying conductance in the instrument circuit, reading directly in units of flow. The flow meter is operated on ordinary a.c. and is unaffected by slight voltage variations. The number of rods in the contact chamber is so great that slight changes of flow are indicated on the meter. The indicating or recording instruments may be placed in any convenient location and connected to the manometer by a 2-wire circuit. (F.T.M.)

FLOW SHEET. Organization Chart.

FLOW, STREAMLINE AIR. Aerodynamics.

FLOW, TURBULENT AIR. Boundary Layer; Turbulence.

FLOWAGE (ROCK). This term, as used by geologists, signifies the internal movement of clays and rocks when stressed beyond the elastic limit. Important types of flowage are: **granulation** and **foliation**, although the latter is primarily a physical-chemical rather than a purely mechanical process, as in the other types of flowage. (R.M.F.)

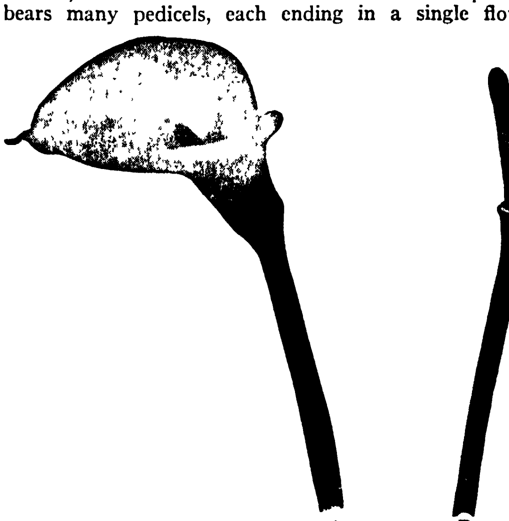
FLOWER. The flower is that part of the plant which is concerned in the sexual reproductive process of angiosperms The formation of the flower is preliminary to the production of **fruit** with its **seeds**.

Flowers may be borne at the tip of a stem or a branch, in which case they are said to be terminal flowers Or they may be borne in the **axils** of leaf primordia and called axillary. In very many plants the structure which subtends the flower does not develop inta a leaf like the other leaves of the plant. Instead, it may remain very small and inconspicuous, or it may grow larger, but be of shape quite unlike that of an ordinary leaf. These structures which subtend flowers are called bracts. In a few plants the bracts are large and brilliantly colored, so that at times they are much more showy than are the flowers. The scarlet bracts of the *Poinsettia* and the white or pink bracts of the Flowering Dogwood are examples. In many **monocotyledons**, as Palms and Arums, there is a single large bract which subtends and often more or less surrounds the flowers. Bracts of this kind are called spathes. The striped "pulpit" of the Jack-in-the-Pulpit and the white bract of the Calla Lily are well-known examples. The bract may surround and protect the flower in the bud.

Flowers may be borne singly or they may be associated in a cluster which is known as an inflorescence. A single flower is called a solitary flower, and the stalk which supports it is a peduncle. The stem which supports an inflorescence is also a peduncle, while the individual flowers of the inflorescence are supported on pedicels.

Anemonella, one of the buttercup family.

When there is a distinct axis extending through an inflorescence it is called a rachis. The arrangement of the flowers of an inflorescence varies in different groups. A common, and primitive, form of inflorescence is the raceme, in which the floral shoot grows at the apex and bears many pedicels, each ending in a single flower.



A B

Spadix of Calla lily. This is not a flower but an inflorescence In the center is a spike, the upper portion of which bears staminate flowers and the lower portion pistillate flowers. The showy white portion is a spathe—a special leaf surrounding the spadix. A, exterior view, B, with spathe removed to show spadix inside.

The first flowers to open are those at the base of the raceme. If, in an inflorescence of this sort, each branch is a raceme bearing several flowers, it is called a panicle, or a compound raceme. If the flowers of the raceme are borne directly on the main axis, the inflorescence becomes a spike. A secondary spike, common in grasses,

is a spikelet. A catkin is a spike which droops. A corymb is a modified raceme in which the lower pedicels of the inflorescence grow faster than the upper ones, so forming a more or less flat-topped cluster. An umbel differs from a corymb in that it has no central rachis, all the pedicels of the inflorescence rising from a common point. More commonly umbels are compound, each of the main stalks of the inflorescence bearing an umbel at its tip. The inflorescence of the onion is an umbel, that of wild carrot a compound umbel. The inflorescence of the **composite family** is a head, which may be considered as an umbel in which the flowers are all sessile, without pedicels, on the apex of the stem. A cyme is an entirely different type of inflorescence. In the cyme the first flower to open is at the tip of the cluster. Below it on the stem are a number of bracts. From the axils of these bracts branches develop and also end in a

Upper portion of *Trillium* plant with whorled arrangement of leaves on the stem.

flower. This successive branching may be many times repeated, but always the flower terminates the stem and opens. Combinations of these types of inflorescences are found in many plants. A spadix is an inflorescence of the spike form with elongated axis, sessile flowers, and enveloping leaf, the spathe.

A flower of *Hippeastrum*, a member of the Amaryllis Family, showing three-parted stigma and the six stamens characteristic of the lily order, surrounded by perianth of six parts arranged in two whorls.

A flower consists of an axis, called the receptacle or torus, and, attached thereto, the pistils, the stamens, the petals, and the sepals. The pistils and stamens are the essential organs of the flower, the petals and sepals are accessory organs. Any flower which has all four organs is a complete flower, while that which lacks one or more

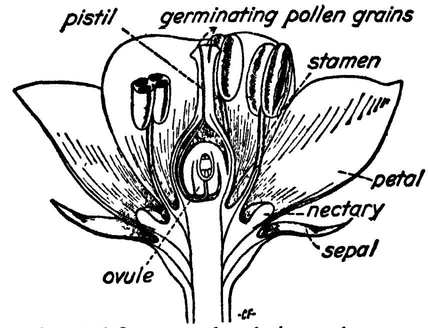


Diagram of typical flower, cut lengthwise to show arrangement of parts. Pollination has occurred. Pollen tube extends toward embryo sac within the ovary.

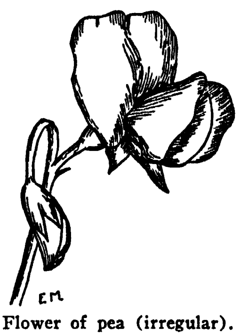
is incomplete. If the organs missing be either stamens or pistils, the flower is imperfect or unisexual. A perfect or bisexual flower has both sets of essential organs. If only the stamens are present the flower is staminate; if only pistils, it is pistillate. If the two kinds of flowers, staminate and pistillate, are found on the same plant, that species of plant is monoecious. When the two unisexual flowers are found on different plants, the species is dioecious. Infrequently flowers are borne which lack both stamens and pistils, and are sterile. When the flower lacks sepals and petals, it is a naked flower.

Flower of Saint John's-wort (polypetalous). The organs of this flower are unusually well exposed to view.

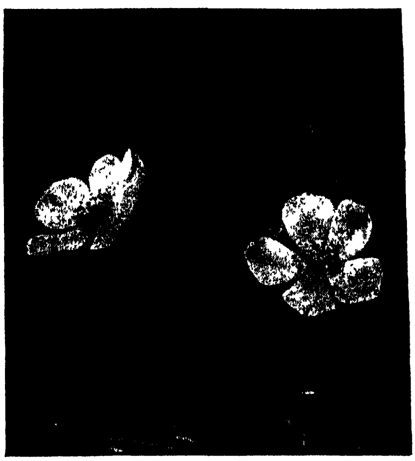
Flowers may also be distinguished as regular and irregular. Regular flowers are those in which all the members of any set of organs are alike, forming a flower which is radially symmetrical or actinomorphic. Often the organs of one or more sets are not alike, forming an irregular flower. An irregular flower may be bilaterally symmetrical or zygomorphic, one half being a mirror image of the other.

The accessory floral organs, the sepals and petals together, constitute the perianth. In the complete flower, the perianth is composed of a whorl of sepals which is

called the calyx and inside the calyx a whorl of petals called the corolla. The sepals are usually green and small. The function of the calyx seems to be to protect the other parts of the flower before the flower bud opens. The petals are usually thin and bright colored or white. The term corolla is applied to all the petals together. The corolla appears in a wide variety of shapes and colors. Its function seems to be to attract animals, especially insects, to the flower and so bring about **pollination**. The number of sepals and petals is constant for each species of plant. In the flowers of monocotyledons there are usually three of each, while in dicotyledons it varies from four to many, with five a very common number. As a further attraction to insects, many flowers possess special glands called nectaries which



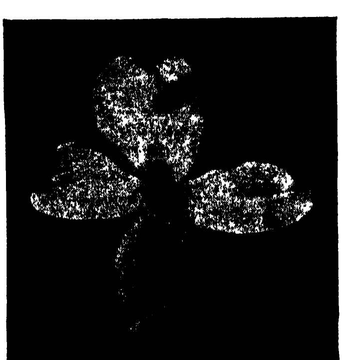
Flower of pea (irregular).



Rosa carolina, a wild species, sometimes cultivated. Notice the large number of stamens and single whorl of petals.

secrete a sweet fluid, nectar. Usually these nectaries are situated at the bases of the petals, though they may be found in many other places in the flower Nectaries known as extrafloral nectaries are found on petioles of leaves or on the stipules.

The stamens, or microsporophylls, taken together constitute the androecium. Usually a stamen consists of



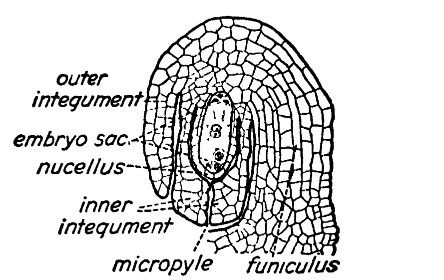
An inflorescence of the flowering dogwood, *Cornus florida*.

two parts, a stalk or filament and an anther. The filament may be short and stout, or more commonly long and slender, raising the anthers well above the base of the flower. The anther when first formed is an undifferentiated mass of cells. As it develops, four groups of cells become set off from the surrounding cells. In these masses, which usually appear as linear strands certain cells undergo **meiosis** and become microspores. The sac which contains them is therefore a microsporangium. A microspore develops into a pollen grain. The anther sac, or sporangium, when mature usually opens by two longitudinal slits, or by special spores, and frees the pollen grains. The number of stamens in a flower varies from one to many. Often there are vestigial stamens, or staminodia, present in the flower; in some plants these are large and brightly colored, in others they are small and inconspicuous.

The pistil is the central organ of the flower. A single pistil or several pistils, which may be separate or partly, or even completely, united, is called a gynoecium. A pistil is composed of one or more modified leaves called carpels or megasporophylls. When there are two or more somewhat united carpels, the pistil is called compound. A pistil is composed of a basal ovary (ovulary), a terminal stigma, and usually an intermediate style, which is often long and slender. The stigma is a receptive organ, the surface of which is often either sticky or hairy. It is to the surface of the stigma that the pollen grains are carried when **pollination** takes place.

The style may be very much elongated to lift the stigma above the other parts of the flower and so increase the probability of pollination. The ovary has one or more cavities, or loculi. In these are located the ovules, which will become the seeds. The ovules are attached to the wall of the ovary or to a central column by a small stalk called the funiculus, through which the developing ovule receives nourishment. That region of the ovary to which the ovules are attached is called the placenta. The number of ovules in a single loculus varies from one to many.

Each ovule first appears as a minute rounded projection on the wall of the ovary or the columella. In the early period of its development this projection consists of an undifferentiated mass of cells known as nucellar tissue. One or two layers of cells, known as the integu-

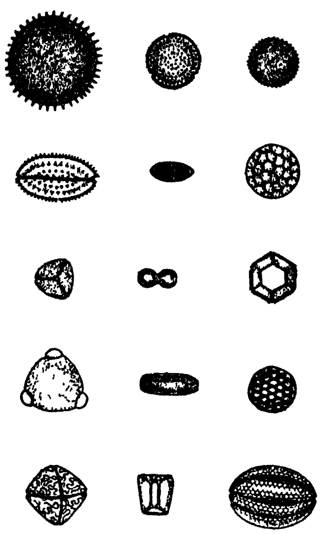


Mature megagametophyte of lily within an ovule. (*Textbook of General Botany, Third Edition, by Holman & Robbins, John Wiley & Sons, Inc.*)

ments, rise from the base of the projection and finally almost completely surround the nucellar tissue. A minute opening through the integuments, called the micropyle, is left connecting the cavity of the ovary to the surface of the nucellar tissue. Within the nucellar tissue a very important series of **cell divisions** has taken place. While there are many variations of the process as it occurs in different species, the process is essentially as follows. Within the mass of nucellar tissue a single cell has become differentiated from all the others by its larger size and denser cytoplasmic content. This is the megaspore mother cell. It divides twice in rapid succession to form a row of four cells. These two rapidly succeeding cell divisions take place in such a way that the four cells have the haploid or reduced number of **chromosomes**. The process is known as **meiosis**. Three of the four cells disintegrate and are lost. The fourth, or

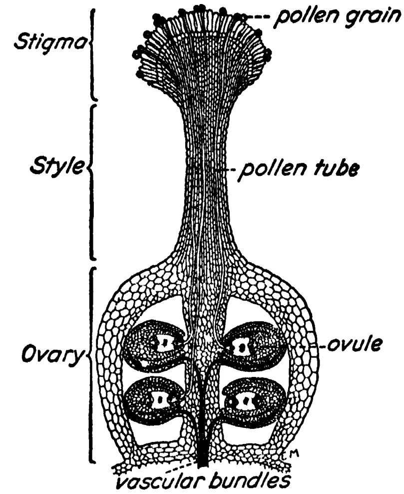
megaspore, is usually the one nearest the micropyle. It enlarges greatly, while by three successive divisions its nucleus divides to form eight nuclei, all contained within the wall of the very much enlarged female gametophyte, commonly called the embryo sac. The arrangement of these eight nuclei is quite uniform. In most plants there are four of them at each end of the embryo sac. One from each end moves to the center of the embryo sac, where they form an intimate association and eventually fuse. These two are the polar nuclei. Of the three nuclei which remain at the micropylar end of the embryo sac, one becomes larger than the other two. This is the egg nucleus or megagamete; the other two form cells which are called the synergids. The three nuclei at the opposite end of the embryo sac form cells called the antipodals. The mature embryo sac is thus a seven-celled body, with seven nuclei.

The pollen grain is carried to the stigma by various agents. The pollen grains of different species of plants are very characteristically shaped, and are often strik-



Pollen grains of various kinds of plants. (*Pope, Botanical Gazette.*)

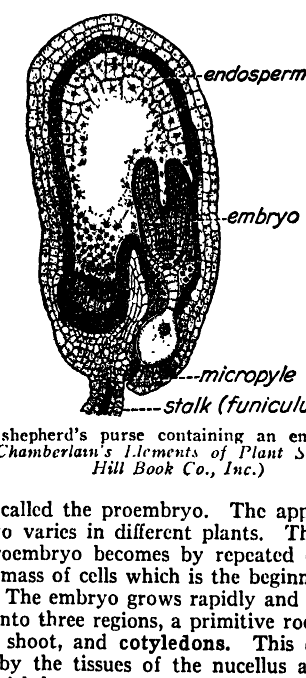
ingly beautiful because of the many ridges or protuberances with which the outer wall is marked. At first a pollen grain contains a single nucleus. This nucleus divides before leaving the anther and gives rise to two nuclei, one of them called the tube nucleus and the other the generative nucleus. The pollen grain germinates when it reaches the stigma, putting out a slender pollen tube which grows down through the tissues of the style and into the ovary. In the pollen tube the generative nucleus divides to produce two sperm nuclei. There it grows towards an ovule, which it enters through the micropyle. The pollen tube continues to grow until its tip reaches the embryo sac. Into this the two sperm nuclei are discharged. One of them fuses with the egg nucleus of the embryo sac, while the other passes to the polar nuclei and fuses with them. The nucleus which is formed by the fusion of these three nuclei is called the primary endosperm nucleus; it contains three times the haploid chromosome complement. The act of fusion of the male nucleus with the egg nucleus is called fertilization. From the endosperm nucleus there is formed by repeated division and subsequent wall formation a mass of triploid tissue known as the endosperm, which surrounds the developing embryo. The endosperm nourishes the embryo during the early stages of its growth. In many plants such as the bean the endosperm is not formed at all or entirely absorbed by the developing embryo, while the seed is still immature; in others the endosperm forms a considerable part of the mature seed.



Longitudinal section of flower pistil showing pollen tubes growing through the style and entering the ovules. Diagrammatic.

Seeds with endosperm are known as albuminous seeds; those without endosperm as exalbuminous seeds.

The act of fertilization causes the immediate growth of the fertilized egg. In most plants a series of cell divisions takes place, forming a short filament of cells



Ovule of shepherd's purse containing an embryo and endosperm. (*Chamberlain's Elements of Plant Science, McGraw-Hill Book Co., Inc.*)

which is called the proembryo. The appearance of the proembryo varies in different plants. The terminal cell of the proembryo becomes by repeated cell divisions a spherical mass of cells which is the beginning of the true embryo. The embryo grows rapidly and becomes differentiated into three regions, a primitive root, or radicle, a primitive shoot, and **cotyledons**. This embryo is surrounded by the tissues of the nucellus and the integuments, which have grown larger to form seed coats coincident with the growth of the embryo. The mature ovule becomes the **seed**, and the ovary which contains it becomes the **fruit**. (R.M.W.)

FLOWER PECKER. Aves, Passeriformes. Brightly colored birds (**Aves**) of the Oriental and Australian regions, related to the sun birds. (A.W.L.)

FLOWERING PLANTS. **Angiosperms.**

FLOW-STRUCTURE. A type of banding in effusive igneous rocks (lavas) due to the alignment of minerals, inclusions or gas cavities during the movement of

the still molten but viscous material. It is not to be confused with foliation. (R.M.F.)

FLUE. A flue is a channel for hot gases. The term is applied more to a channel for gases composing the products of combustion of a fuel than anything else. While frequently constructed of masonry or tile, or similar material, flues may also be sheet metal. Fire-tube **boilers**, in which the hot gases pass through the inside of instead of around the tubes, are said to have flues, since the tubes themselves are often so described. The **chimneys** which carry off the wastes of **combustion** from domestic fires are called flues, though flue refers more specifically to the space provided for passage of the gases, whereas chimney is inclusive, and one chimney may contain more than one flue, and may have architectural embellishments which are entirely independent of the flue. Boiler flues are generally seamless, welded, or riveted flues 5 to 18″ in diameter. Chimney flues should carry a lining of material which, by its smoothness, reduces friction loss, and by its **refractoriness**, is able to withstand continued heating and cooling without cracking or deteriorating in other ways, and which provides a continuous lining free from cracks which might cause a fire hazard by allowing hot gases to seep through the cracks in the masonry comprising a chimney. Flue-lining materials are **fire-brick,** plastic refractory **cement,** and hard burned **terra cotta** tile. (F.T.M.)

FLUE GAS. Since the products of **combustion** of a fire are eventually led to the atmosphere through the **flues** of a **chimney,** the products of combustion are commonly referred to as flue gas. The fuel elements of all commonly used fuels are **carbon** and **hydrogen.** As air containing **oxygen** and **nitrogen** is supplied to make combustion possible, and as some **excess air** is generally needed, flue gas may be expected to be a composite gas composed of the following: Carbon dioxide, carbon monoxide, oxygen, nitrogen, and steam. There should be little or no carbon monoxide, for that is indicative of faulty or incomplete combustion. The oxygen content should be as low as it may be made consistent with maintenance of complete combustion. Since air is so largely composed of the inert gas nitrogen, the bulk of flue gas is also nitrogen. A typical analysis of dry flue gas by volume as produced by a coal fire, well tended, would be carbon dioxide, 12%; oxygen, 8%; nitrogen 80%. (F.T.M.)

FLUE GAS ANALYSIS. While poor **combustion** of **fuel** is frequently detectable by the evolution of dense clouds of smoke, smokeless combustion may not necessarily be the best possible that may be obtained in the circumstances, since unnecessary quantities of **excess air,** or the product of incomplete combustion, **carbon monoxide,** may be present to render combustion inefficient, even though the flue gas is not badly colored. The flue-gas content is the fireman's best indication of actual combustion conditions. The combustion of coal or oil can be accurately gauged simply by the **carbon dioxide** content of the flue gas as long as the same fuel is employed. Consequently, the operating meter need record only carbon dioxide. However, for combustion test purposes, including performance runs for **boiler efficiency,** checking boiler operation, etc., complete analysis of the four principal gases in the products of combustion is required. For this analysis the Orsat apparatus is indispensable; indeed, the analysis is usually referred to as Orsat analysis. The apparatus conceived by that eminent French chemist analyzes a measured volume of a mixture of gases by the process of absorption. The volume remaining is measured, thus indicating by differences the gas absorbed. The remainder is then exposed to another reagent, which removes another gas. Upon remeasurement, the volume of that gas becomes known, and this process is continued a third time, so that the percentages of carbon dioxide, carbon monoxide, and **oxygen** are determined. The remainder is assumed to be **nitrogen,** as it, in fact, is, for all practical purposes. The analysis obviously is one by volume, and on account of the construction and use of the apparatus, it is made at atmospheric pressure and temperature. (F.T.M.)

FLUID FLOW. An ideal fluid is one which is not only continuous and homogeneous, but also incompressible. In addition, it should be inviscid, and should have physical properties which are unaffected by variations of temperature or pressure. A liquid resembles this ideal fluid more than does a gas, and consequently behaves with a great deal more regularity in fluid flow. A fluid flow may be steady or unsteady, depending on whether the flow passing any given cross-section of the conduit is constant. Furthermore, it may be uniform or non-uniform if, at different points along the flow, the velocity varies, due to changes of area or pressure. It also may be turbulent or laminar.

No fluid fulfills the requirements of the ideal fluid. All actual fluids have a certain amount of **viscosity** and compressibility. An essential of fluid flow is that continuity be satisfied by equal inflow and outflow from a certain region within a given period of time. A fluid flow is often thought of in the terms of streamlines, which are imaginary lines drawn in such a way that they are tangent to the direction of fluid motion. No quantity of the fluid may cross a streamline.

Elementary hydraulics always includes **Bernoulli's law,** and it is repeated here as being of great importance to the subject of fluid flow.

Bernoulli's law is:

$$\frac{p}{W} + \frac{v^2}{2g} + z = \text{a constant},$$

and the symbols are defined as follows:

p = static pressure in lbs per sq. ft.
W = specific weight of fluid in lbs. per cu. ft.
v = velocity in ft. per sec.
g = gravitational acceleration in ft. per sec. per sec
z = potential, or "elevation," head in ft.

Bernoulli's law states that in steady flow, the total head is a constant at any point and equal to the sum of the pressure head $\left(\frac{p}{W}\right)$, the velocity head $\left(\frac{v^2}{2g}\right)$, and the potential head (z). Since there is actually a loss of head between any two points due to friction, the difference between the total heads at any two points must equal the friction head when the flow is steady.

In this equation, $\frac{v^2}{2g}$ represents the velocity head, a pressure which could be recovered by the efficient reduction of the velocity in a conduit of expanding cross-section. When this velocity head is multiplied by the specific weight of the fluid, it is reduced dimensionally to the unit of pressure, lbs. per sq. ft., and may be designated the dynamic pressure, in counter distinction to the static pressure p. In the case of an expansionable fluid, such as gas, the total energy at two points in the flow must be the same, that is, the heat energy plus the kinetic energy of motion must be constant. It is necessary to invoke this law of continuity of energy in dealing with the flow of gases or vapors through nozzles. (See **Fluid Friction Orifice, Weir, Nozzle, Pitot Tube, Flow Meter, Aerodynamics, Boundary Layer.**) (F.T.M.)

FLUID FRICTION. The flow of any actual fluid must of necessity be attended by the presence of **friction,** due to the physical nature of fluids, none of which meets the requirements of the ideal fluid, as mentioned in **fluid flow.** A great deal of time and attention have been devoted to the study of the properties of a flowing fluid. The frictional effects present in the flow of

liquids have been rationalized much more thoroughly than for vapors and gases. However, for all three the friction is found to depend upon the nature of the fluid itself, its **viscosity**, and upon the conduit which contains it. On account of the different molecular arrangement of liquids, vapors, and gases, the study of friction of fluids has become a specialized study of each of these three.

Fluid flow rarely follows the commonly accepted idea of **streamlines**, since the velocities necessary for viscous flow of this nature are almost always lower than those found expedient to employ. Most flows are turbulent in nature, and become turbulent at a definite velocity, the value of which was studied by Reynolds, and is incorporated in the well-known **Reynolds Criterion.** A general thermodynamic equation of energy of a fluid under flow conditions would be as follows:

> Gain in kinetic energy + gain in potential energy + net work received + energy liberated by any chemical change = change in heat content between two states.

In the case of a liquid, this equation can be considerably simplified:—in fact, it becomes **Bernoulli's** well-known equation—but in the case of compressible fluids, which may also undergo some change of form, such as condensation or compression, the longer equation applies. Most practical problems in fluid friction arise in connection with the flow of fluid through pipes, and for an extended discussion, including formulae, the reader is referred to **pipe friction.** (F.T.M.)

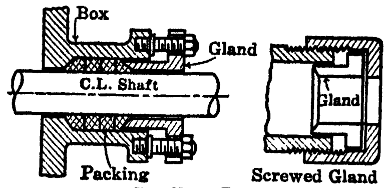
FLUID MECHANICS. Mechanics.

FLUID SEALS. Fluids are occasionally required to be held under pressure in enclosed regions through the walls of which one or more moving shafts must protrude. Unless a seal is provided the fluid will leak through the clearance, left for mechanical reasons between shaft and container, if its pressure exceeds that of the surroundings, or it will be diluted by inflow if at a lower pressure. Such seals are not difficult to provide if the shaft has no motion other than axial rotation or reciprocation. Common examples of such seals are (1) the "stuffing boxes" of double-acting reciprocating compressors, pumps, and engines where the piston rod passes through the cylinder, and (2) the stuffing boxes and "glands" of centrifugal pumps and steam turbines where rotating shafts protrude from the casing. **Piston rings,** although not described here, could be called fluid seals, as could also the method of sealing off fuel gas in large telescoping gas holders ("gas tanks") with a liquid. There are several applications of the floating inverted bell as a gas holder using a liquid seal.

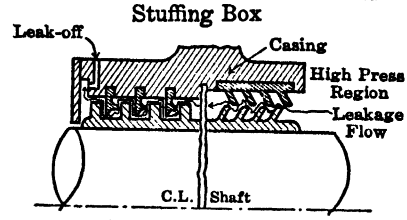
A stuffing box is a recess in the wall surrounding the point of exit of the shaft, arranged to receive a soft and pliant packing such as treated hemp, or leather, which is compressed in the box and pressed firmly against the shaft by the pressure exerted against it from a *gland.* The gland is tightened against the packing by screw threads until leakage is reduced to a negligible amount but not enough to produce seizure or excessive frictional heating of the shaft.

Stuffing boxes are used primarily to seal against leakage around small shafts. Leakage glands are preferred for large diameter shafting—or whenever no mechanical contact is wanted in the seal. A typical example is the *labyrinth gland* of the steam turbine. Here the steam is allowed to flow through the clearance space but is given so many turns that the fluid friction and vortices resulting from numerous changes of direction account for the pressure difference across the gland with only a small flow of the fluid through it.

The diagram shows an outflow of leakage steam. When a vacuum exists inside the casing there would be an air inflow through this gland. To prevent this the gland may be designed for admission of high-pressure steam or water to its midpoint, from which there is two-way leakage flow to the edges. Thus water or condensable steam replaces air inflow. (F.T.M.)



Stuffing Box



Labyrinth Gland
Showing Two Variations

FLUKE. 1. A parasitic flatworm. **Trematoda.** These worms attack many species of animals, passing through a complicated life cycle involving two or three hosts. The liver-fluke of the sheep, which spends part of its life in the body of a snail and becomes adult in the liver of the sheep, is a well-known example. A number of species attack man, particularly in the Orient and in warmer countries. They fall into four groups, the liver, lung, blood and intestinal flukes, depending on the part of the body in which they thrive. 2. The broad horizontal lobes of the whale's tail. 3. A fish, Paralichthys dentatus, belonging to the flatfish family. (A.W.L.)

FLUME. An open channel for conveying water for some special purpose, such as water power, washing, etc., is a flume. Flumes are frequently constructed of lumber having the boards placed in the direction parallel to the flow, these often being planed on the wetted side. However, flumes are also constructed of concrete, brick, etc. The flow in a flume is created by the slope of the bottom, releasing a certain amount of energy of position, which is converted into energy represented in the friction between the water and the flume, provided the flow in the flume is uniform. (F.T.M.)

FLUORSPAR. Fluorite.

FLUORESCEIN. Dyes.

FLUORESCENCE. Luminescence.

FLUORESCENT LAMP. Lamp, Electric.

FLUORINE. Symbol: F. Atomic number: 9. Atomic weight: 19.00. Density: 1.70 grams per liter, 0° C., 760 mm., or 1.31 when air equals 1.00. Melting point: −223° C. Boiling point: −187° C. No isotope, but of single atomic form: 19.

Fluorine is a pale yellow gas, poisonous, very reactive, combines with most other elements in the dark, except it does not combine with oxygen. Discovered by Scheele in 1771, but first isolated by Moissan in 1886, by **electrolysis** of fused potassium hydrogen fluoride in a **platinum** apparatus.

Flourine occurs as **calcium** fluoride (CaF_2) in the mineral **fluorite,** fluorspar, as sodium **aluminum** fluoride (Na_3AlF_6) in the mineral **cryolite** in Greenland, and with **calcium** phosphate as **fluoride** in the mineral **apatite.**

Acids: **hydrofluoric acid** (H_2F_2); hydrofluoboric acid (HBF_4) (see **Boron, Acids**); hydrofluosilicic acid (H_2SiF_6) (see **Silicon**).

Borofluoride: (See **Boron.**)

Bromide: Trifluorine bromide (F_3Br).

Fluoborate: (See **Boron.**)

Fluorides: **Sodium** fluoride (NaF), sodium hydrogen fluoride ($NaHF_2$), **potassium** fluoride (KF), potassium hydrogen fluoride (KHF_2), **ammonium** fluoride (NH_4F), ammonium hydrogen fluoride (NH_4HF_2), **silver** fluoride (AgF) are soluble fluorides; **calcium** fluoride (CaF_2), **strontium** fluoride (SrF_2), **barium** fluoride (BaF_2), **magnesium** fluoride (MgF_2) are insoluble fluorides. (See **Hydrofluoric Acid.**)

Fluosilicate: (See **Silicon.**)

Hydride: Hydrogen fluoride (H_2F_2), colorless gas, of marked odor, poisonous, melting point −83° C., boiling point 19° C., very soluble in water yielding hydrofluoric acid. Formed by reaction of calcium fluoride and concentrated sulfuric acid upon heating. Hydrogen fluoride etches glass by reaction with silicate, forming volatile silicon tetrafluoride; forms hydrofluosilicic acid (see **Silicon**), hydrofluoboric acid (see **Boron**) and fluorides.

Iodide: Pentafluorine iodide (F_5I).

Silicofluoride: (See **Silicon.**)

Organic compounds: Organic fluorine compounds are made by reaction of the corresponding paraffin chloro-compounds with silver fluoride, mercurous fluoride, antimony trifluoride, titanium tetrafluoride, and the benzenoid fluoro-compounds by the diazo-reaction using hydrofluoric acid.

REPRESENTATIVE ORGANIC COMPOUNDS OF FLUORINE

			Boiling Points
1.	Methyl fluoride (Fluoromethane)	CH_3F	−78° C.
2.	Ethyl fluoride	C_2H_5F	−32
3.	Normal-propyl fluoride (1-fluoropropane)	$C_2H_5\cdot CH_2F$	−3
4.	Iso-propyl fluoride (2-fluoropropane)	$CH_3\cdot CHF\cdot CH_3$	−11
5.	Allyl fluoride	$CH_2{:}CH\cdot CH_2F$	
6.	Benzoyl fluoride	$C_6H_5\cdot COF$	161 (745 mm.)
7.	Fluorobenzene (Phenyl fluoride)	$C_6H_5\cdot F$	85
8.	Ortho-fluorobenzoic acid	$C_6H_4(F)(2)(COOH)(1)$	121
9.	Meta-fluorobenzoic acid	$C_6H_4(F)(3)(COOH)(1)$	124
10.	Para-fluorobenzoic acid	$C_6H_4(F)(4)(COOH)(1)$	183
11.	Fluorodichloromethane	$CHFCl_2$	14
12.	Fluorotrichloromethane	$CFCl_3$	25
13.	Difluorodichloromethane ("freon")	CF_2Cl_2	−29
14.	Para-fluorobromobenzene	$C_6H_4F(4)Br(1)$	
15.	Para-fluoroiodobenzene	$C_6H_4F(4)I(1)$	
16.	Fluoroform	CHF_3	20 (40 atm.)
17.	Benzotrifluoride	$C_6H_5\cdot CF_3$	
18.	Carbon tetrafluoride	CF_4	−128

(R.K.S.)

FLUORITE. The mineral fluorite, **calcium** fluoride, CaF_2 is an isometric mineral with cubic habit, although **octahedrons** and **dodecahedrons** are not uncommon. Penetration twins are frequent. Fluorite may be also massive, granular to compact. It has a very perfect octahedral cleavage; brittle; hardness, 4; specific gravity, 3.01–3.25; luster, vitreous; color may be white or colorless, blue, blue-green, yellow, brownish-yellow or red. The blue kinds are often a delicate violet-blue, sometimes amythestine in tint. The streak is white; translucent to transparent. Certain specimens appear blue by reflected, green or yellow by transmitted light. Fluorite sometimes **phosphoresces** when heated or scratched, other varieties **fluoresce** beautifully under the influence of **x-rays** or **ultra-violet** light. Fluorite may occur as a vein deposit especially with the metallic minerals where it often forms a part of the gangue and may be associated with **barite, quartz** and **calcite.** It is a common mineral in the deposits of **pneumatolytic** origin and has been noted as a primary mineral in granites and similar rocks. One of the most famous of the older localities is Derbyshire, England, where under the name of Derbyshire "blue john" beautiful blue fluorite is used for ornamental purposes; its softness, however, has been a bar to its general use. It is found also in Cumberland, England, Saxony, Bavaria, Baden, Austria, Czechoslovakia, Norway, Switzerland, and Italy. Colorless, transparent fluorite was formerly mined at Madoc, Province of Ontario, Canada; and in the United States has been found at Westmoreland and Chatham, N. H.; Trumbull, Conn.; Jefferson and St. Lawrence Counties, N. Y.; at Phoenixville, Pa.; Amelia Court House, Va.; and in commercial quantities in Kentucky and Illinois. It is used as a flux in the manufacture of **steel**, in making opalescent **glass, enamels** for cooking utensils, and for hydrofluoric acid. Its rare use for ornaments is due to its softness, above referred to. The name fluorite is derived from the Latin *fluo,* flow, in reference to its use as a flux. (E.S.C.S.)

FLUOROSCOPE. This device consists of a fluorescent screen mounted on one wall of a dark box having a hooded opening opposite to it into which an observer may look. When **x-rays** or other exciting radiations fall on the screen it glows brightly. The fluoroscope is generally used to observe x-ray shadows cast by parts of the human body or by other objects and, therefore, serves as a convenient means of making preliminary x-ray examinations. A material commonly used for the screen is barium platino-cyanide. (See **Luminescence.**) (L.D.W.)

FLUTTER. Oscillation of definite period but unstable character set up in any part of an aircraft by a momentary disturbance, and maintained by a combination of aerodynamic, inertial, and elastic characteristics of the member itself (example, buffeting). (See **Wing, Airplane.**) (F.T.M.)

FLUVIAL. Derived from the Latin, meaning river, and used by geologists and physiographers to denote a river as the agent, i.e., fluvial sediments. (R.M.F.)

FLUX. One use of the term flux is to designate a material which by its chemical action facilitates the **soldering** and **brazing** of metals. Such a flux applied to a metallic surface cleans it and renders it receptive to amalgamation with the solder or brazing metal. Some fluxes are **resin**, for soldering tin; muriatic acid, for galvanized **iron** and other **zinc** surfaces; and **borax**, for brazing.

A related use of the term flux is to designate the material added to the contents of a smelting furnace or a **cupola** for the purpose of purging the metal of impurities, and of rendering the slag more liquid. The flux most commonly used in iron and steel furnaces is limestone, which is charged in the proper proportions with

the iron and fuel. The slag is a liquid mixture of ash, flux, and other impurities.

Magnetic flux is a term used in magnetism. A **magnetomotive force** will cause magnetic lines of force through a magnetic circuit. It is similar to a current flow created by voltage in an electric circuit. The magnetic flux is the number of lines of magnetic force set up in a magnetic substance, and thus flux becomes analogous to the current flowing in an electric circuit. The magnetic flux is numerically equal to the driving force called magnetomotive force, divided by the **reluctance** of the circuit, which is a quality analogous to the resistance of an electric circuit. The unit of the magnetic flux is the maxwell, and flux density is measured in units of maxwells per sq. cm., or gausses. (F.T.M.)

FLUX REFRACTION. This term refers to the fact that when a ferromagnetic body composed of two pieces of different magnetic **permeability** is placed in a magnetic field, or when a **dielectric** composed of two adjacent portions of different dielectric constant is placed in an electric field, the lines of magnetic induction in the former case, and the lines of electric displacement in the latter, if oblique to the interface, abruptly change their direction. The phenomenon is thus somewhat analogous to the **refraction** of light. But the law is different. Whereas, in the case of light the ratio of the sines of the angles of incidence and refraction is constant, in the case of flux refraction it is the ratio of the tangents of the angles that is constant.

For an electric current flowing across a boundary between two conductors of different electrical resistivity, there is a refraction of the lines of flow, likewise obeying the tangent law. (L.D.W.)

FLY. A 2-winged insect belonging to the order **Diptera.** Also commonly applied with some qualifying word to many flying insects with membranous wings, such as May fly, dragon fly, stone fly, and caddis fly. These four examples belong to as many different orders. (A.W.L.)

FLY CUTTER. Milling.

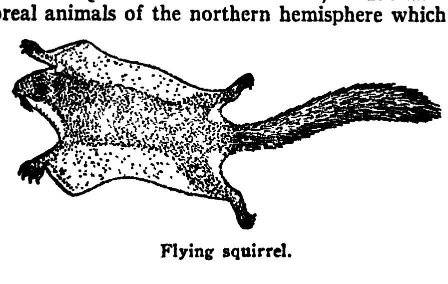
FLYCATCHER. Aves, Passeriformes. Insect-eating birds (**Aves**) of many species and world-wide distribution. The North American species belong to the family Tyrannidae and include the **kingbirds**, the wood **pewee**, and the **phoebes**, in addition to the several species named as flycatchers. (A.W.L.)

FLYING BOAT. Seaplane.

FLYING FOX. Bat.

FLYING LEMUR Mammalia, Insectivora. An arboreal Malayan animal, *Galeopterus temminckii,* of nocturnal habits. It glides from tree to tree by means of folds of skin stretching between the fore and hind legs and thence to the tail. A similar species, *Galeopithecus volans,* lives in the Philippine Islands. Both eat leaves and fruits. Not a true lemur, hence the names cobego and kaguan by which these animals are also known are less misleading. (A.W.L.)

FLYING SQUIRREL. Mammalia, Rodentia. Small arboreal animals of the northern hemisphere which glide by means of skin folds along the sides of the body from front to hind legs. They belong to the genus *Sciuropterus.* Their appearance is much like that of squirrels but they are as closely related to the ground squirrels and gophers. The African flying squirrels belong to a different family, the Aromaluridae. (A.W.L.)



Flying squirrel.

FLYWHEEL EFFECT. Since the main purpose of applying a flywheel to any machine is to steady the speed, any similar action or arrangement of apparatus to produce such action might be called flywheel effect. The ability of a flywheel to steady speed lies in its capacity to absorb and release energy with small variations in speed. Now since the **kinetic energy** contained by a rotating flywheel is $\frac{1}{2}I\omega^2$, I being the **moment of inertia** of the **mass** about the center of rotation, ω being the angular velocity in radian units, energy will be absorbed when ω changes slightly only upon the condition that I be a large quantity. Consequently, flywheels are characterized by large moments of inertia. Mass alone is no criterion of flywheel effect, since moment of inertia involves as well the disposition of the mass; in other words, the shape of the body. Hence flywheels are not only massive, but the mass is placed as far as practicable from the center of rotation, as in a heavy rim. Flywheel effect, then, is to be secured wherever large masses having large amounts of inertia about the center of rotation are steadying rotational motion in the face of uneven power impulses by the absorption or release of kinetic energy by slight changes of angular rotation.

In the hydraulic turbine field, flywheel effect has a very definite and special meaning. The flywheel effect of a hydraulic turbine is the weight of its rotating element, multiplied by the square of the **radius of gyration** of the same. (F.T.M.)

FOAMING. Feed-Water Treatment.

FOCAL INFECTION. A localized infection. Formerly, it was thought that such infections might produce symptoms in other parts of the body by absorption of "toxins" liberated by bacteria. It is now believed that such occurrence is exceedingly rare. The most common sites of focal infection are the tonsils, teeth, paranasal sinuses, genito-urinary tract, appendix and gall bladder. (D.M.H.)

FOCAL LENGTH. Mirrors and Lenses.

FOCAL POWER. Mirrors and Lenses.

FOCI OF A CONIC. Conic Sections.

FOEHN WIND. On the lee side of mountains air flowing downhill dry-adiabatically with attendant heating. In western North America along the slopes of the Rockies, foehn winds are called **Chinooks.** (P.E.K.)

FOG. Condensation and consequent formation of water droplets (or ice crystals) in the air at the earth's surface will produce a fog. Fogs are classified in many ways. One of the simplest is the use of formation cause or process as a basis for differentiation among the various types.

1. Advection fogs are fogs that owe their existence to the flow of air from one type of surface to another Surface temperature contrast between two adjacent regions is necessary in causing the formation of advection fogs.

a. The usual type of advection fog is formed when relatively warm and moist air drifts over much colder land or water surfaces. Examples of this type are found over land when moist air drifts over snow covered areas, or over water when moist warm air drifts over currents of very cold water. The latter happens with southerly or easterly winds blowing from the Gulf Stream over the Labrador Current.

b. Coastal and lake advection fog forms when warm and moist air flows offshore onto cold water (summer), or when warm moist air flows onshore over cold or snow covered land (winter).

c. Sea smoke, arctic fog, or steam fog forms in very cold air when it flows over warm water.

2. Radiation fog is a type that develops in nocturnally cooled air in contact with cool surface. Radiation fog forms over land and not over water because water surfaces do not appreciably change their temperature during hours of darkness.

3. Upslope fog is caused by dynamic cooling in air flowing uphill. Upslope fog will form only in air that is convectively stable, never in air that is unstable, because instability permits the formation of cumulus clouds and vertical currents.

4. Precipitation fog forms in layers of air which are cooler than the precipitation which is falling through them. The greater the temperature difference between relatively warm rain (or snow) and the colder air layer, the more rapidly will the fog develop. Fogs associated with fronts are largely precipitation fogs.

Visibility in fogs varies from a few feet up to a mile. Often in a fog blanket all ranges of visibility are present. (P.E.K.)

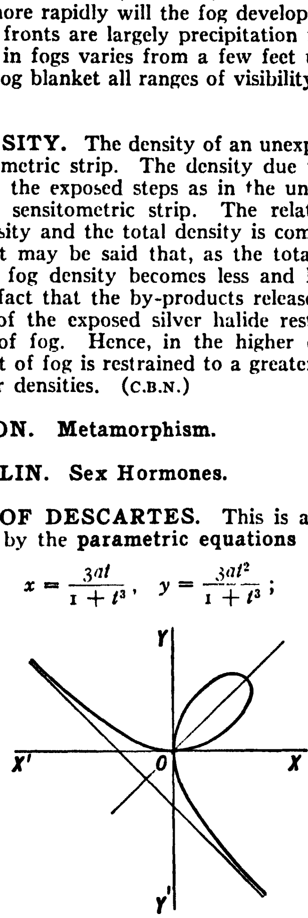
FOG DENSITY. The density of an unexposed portion of a sensitometric strip. The density due to fog is not the same in the exposed steps as in the unexposed portion of the sensitometric strip. The relation between the fog density and the total density is complicated, but in general it may be said that, as the total density increases, the fog density becomes less and less. This is due to the fact that the by-products released in the development of the exposed silver halide restrain the development of fog. Hence, in the higher densities, the development of fog is restrained to a greater degree than in the lower densities. (C.B.N.)

FOLIATION. **Metamorphism.**

FOLLICULIN. **Sex Hormones.**

FOLIUM OF DESCARTES. This is a plane curve represented by the **parametric equations**

$$x = \frac{3at}{1 + t^3}, \quad y = \frac{3at^2}{1 + t^3};$$



Folium of Descartes.

its equation in **rectangular coordinates** is

$$x^3 + y^3 - 3axy = 0.$$

It is shown in the accompanying figure. (L.L.S.)

FOLLICLE. In zoology, a glandular cavity or sac. The small spherical chambers in the thyroid gland, the fluid-filled cavity in the vertebrate ovary in which the ovum develops, and the chambers of the **arthropod** testis are examples of the application of the term. For the use of the term follicle in botany, see **Fruit.** For its detailed physiological discussion, see **Menstruation.** (A.W.L.)

FOLLICLE CELL. Cells of the ovarian follicle which nourish the ovum during its development. They occur in the Graafian follicles of vertebrates and in the open follicles of invertebrates. In the insects specialized cells of similar function contained within the follicle are termed nurse cells. (A.W.L.)

FOLLOWER. **Cam; Milling; Lathe.**

FOMALHAUT. Fomalhaut (Pisces Australis) is interesting as the most southern first-**magnitude** star visible from the latitude of New York. It rises almost simultaneously with **Capella** and is above the southern horizon during the evening in the autumn months. It was one of the Royal stars of **astrology,** ruling over the southern sky. The astrologers believe the star to portend eminence, power, and fortune to those born under its influence. (W.K.G.)

FONTANELLE. Any one of the places in an infant's skull that have not become bony. These places are usually situated at the junction of different bones forming the dome of the skull. At the age of 1 year they are normally filled in with bone. Fontanelles also occur in the skulls of other vertebrates, in their immature form. (R.S.M., A.W.L.)

FOOD. The raw material taken into the body of a living organism as a source of energy and material for the renewal of its own structure. The food of animals is chiefly organic, consisting of plant or animal tissue, either dead or alive, or waste products. The food must contain **protein** or another source of **nitrogen.** Animals can live on this substance alone but not on **fats** or **carbohydrates** without a nitrogenous compound to supplement them.

Food materials for human use should be (1) digestible, furnishing materials and energy adequate for body functions, (2) pure, not furnishing materials deleterious or capable of becoming deleterious to body functions, (3) palatable, of agreeable odor and taste, (4) such that a proper amount of indigestible roughage and bulk are furnished.

The first and fourth criteria, those of digestibility and indigestibility, are related directly to the composition of foods as such, and the changes undergone by foods in the body organs. The purity and palatability are largely affected by conditions outside the body, as by the methods used in gathering, storing and preserving, and in preparation for use. A satisfactory diet must supply sufficient amounts and kinds of various food materials to maintain health, and supply sufficient energy. It has been demonstrated that certain accessory materials such as the **vitamins** must be present in foods or must be supplied otherwise, in order to maintain health and prevent disease.

Flesh of terrestrial and marine animals, milk, fruits, and cereal grains seem to have been the principal diet of primitive men. One writer states that all civilizations have been built around some cereal grain as the principal source of food, and cites rice in Asia, wheat and rye in Europe, millet and sorghum in Africa, and Indian corn in America. In the United States, the average distribution of foods consumed has been estimated as meat and dairy products 37%, fish 2%, cereals 31%, Irish and sweet potatoes 13%, other vegetables 8%, miscellaneous foods 9%.

The non-skeletal portion—muscles and vital organs—of the human body are made up of about ¾ water and ¼ solids. These solids consist of about ¾ protein. Foods, therefore, must supply ample amounts and varieties of proteins. (See **Aminoacids, Polypeptides, and Proteins** for further data on proteins and food composition.) The sources are of animal or vegetable origin

The former include meats, poultry, fish, eggs, milk and cheese. The solid matter of all of these except fish and milk is approximately ½ protein and ½ fat (about ⅔-¾ of the total weight is water). In fish the ratio of protein to fat is frequently considerably greater than the above. Milk contains about 3.3% protein, 4% fat, 5% lactose and the remainder water. The milk product, cheese, contains protein, with fat varying from all in the milk to practically none, depending upon the quality of milk used.

FOODS

Meats, Poultry, Fish, and Eggs

(See **Aminoacids, Polypeptides, and Proteins; Esters** (for fats))

Food—Edible Portion	Protein	Fat	Ash
Beef	18%	13-22%	0.9%
Pork	9	55	0.5
Lamb	18	23	1.1
Fowls	19	16	1.0
Salmon	22	13	1.4
Halibut	19	5	1.0
Eggs	13	10	1.0

Milk and Cheese

Food	Protein	Fat	Sugar	Ash
Milk	3.3% (3-6)	4% (3-4)	5%	0.7
Cheese	18-30	27-37	....	....

Nuts

Food—Edible Portion	Protein	Fat	Carbohydrates Non-cellulose	Cellulose (fiber)	Ash
Peanuts	25.8%	38 6%	22%	2 5%	2 0%

Lettuce	1 2	0 3	2	1	1
Spinach	2.1	0.3	2	1	2

FOOD ADJUNCTS

Water (See **Water**)
Coffee, Tea } Contain caffeine, tannin and volatile oil (caffeol of coffee contributes the characteristic aroma)
Carbonated beverages
Alcoholic beverages
Salts
Spices
Vinegar
Flavoring extracts
Sugar, starch, water, it may be remarked, are the only pure individual chemicals of the 70-odd substances mentioned above. The others are mixtures.

Fats and carbohydrates furnish only three chemical elements, namely, carbon, hydrogen, oxygen, to the body, and proteins only these three and nitrogen and sulfur. The remaining elements required by the animal organism (see **Biochemistry**) are in the ash when food materials are burned in air. Study of the ash gives no information as to the *form* of chemical existence of the contained elements present in the food before burning, but simply proves their presence.

Calcium is so important for the growth of bones that special attention should be paid not only to its supply but to proper conditions for its assimilation. The proper assimilation of calcium and phosphorus are dependent upon the presence of vitamin D (see **Vitamins**) in the diet or upon sunlight.

Iodine is necessary for the proper functioning of the thyroid gland and iron for the haemoglobin of the blood.

ENERGY-PRODUCING VALUE OF VARIOUS FOODS

Carbohydrates:

Glucose	3.75 calories per gram
Sucrose	3.96
Starch	4.22
Glycogen	4.22

About 98% absorbed, so that the average physiological fuel value is about 4 calories per gram.

Fats:

Butter fat	9.2 calories per gram
Animal fats	9.4
Vegetable fats	9.4

About 95% absorbed, so that the average physiological fuel value is about 9 calories per gram.

Proteins:

Casein	5.85 calories per gram
Albumin	5.80
Gelatin	5.30
Gliadin	5.74
Legumin	5.62
Edestin	5.64

About 92% absorbed. Deducting the fuel value of the nitrogenous materials eliminated in the urine, e.g., urea 2.53 calories per gram (or 0.9 calorie per gram protein), creatinine, uric acid, the average net physiological fuel value is about 4 calories per gram.

The chemical analysis of a foodstuff does not throw light upon certain aspects of its dietary properties. The use of biological methods is necessary to ascertain the effectiveness of foods for the maintenance of growth in the young, health at all ages, and resistance to certain diseases. (See **Vitamins.**)

In milk, vitamins A, B, C, D occur in fairly well-balanced proportions. A quart of milk each day for every child and a pint for every adult, including that used in cookery, is the minimum amount recommended. Weight for weight, egg yolk contains 10 times as much vitamin A and 2 times as much vitamin B as milk. Nuts, meats and cereals are low in vitamins A and C. Fish liver oils are desirable to supply vitamin D, but sunlight, milk or egg yolk compensate.

A varied diet supplying energy foods—sugar, starch, fats, protein—supplemented by protective foods—milk, eggs, fresh fruits, green vegetables—appears to furnish all the dietary demands. The table on page 600 presents a summary of some important data regarding foods:

The treatment which foods undergo before being used is of great importance from the points of view of digestibility and palatability. Starch-containing foods are generally heated to render them edible. The treatments may be classified as follows:

1. Cooking
   Boiling, grilling, baking, frying
2. Preservation
   Cold storage, freezing, drying and evaporating, canning, preserving with sugar, vinegar, brine, smoking
3. Bleaching and Coloring
4. Flavoring

On account of the widespread adoption of refrigeration, data on the proper storage temperature of various foods is given.

PROPER STORAGE TEMPERATURE FOR VARIOUS FOODS

Meats, fresh	29–33° F.
Fowls	26–30
Fish, fresh	20–28
Canned meats	35–40
Eggs	31
Milk	35
Cheese	34
Butter	18–20
Lard	38
Oranges	34–45
Lemons	33–45
Bananas	34
Apples	32–36
Pears	34–36
Peaches	34–36
Canned fruits	35–40
Grapes	34–36
Cantaloupes	40
Berries	36
Potatoes	36–40
Carrots	34–35
Parsnips	34–35
Onions	36
Cabbage	34–35
Flour	36–40
Nuts, dried	35–40

For list of approved food colors, see **Dyes.** (R.E.S.)

SUMMARY OF SOME IMPORTANT DATA REGARDING FOODS

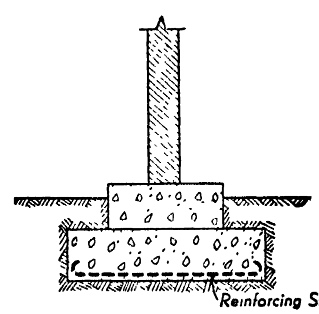
FOOT. 1. The ventral protuberance of the body of a **mollusk**, usually an organ of locomotion. 2. The terminal portion of a jointed appendage which comes into contact with the supporting surface In quadrupedal **vertebrates** the term is applied to both fore and hind appendages and in bipedal forms to the latter only. (A.W.L.)

FOOT CANDLE. A unit of illumination. The illumination in foot candles may be computed from

$$L = C/d^2$$

where L is the illumination in foot candles, C is the candle power of the source and d is the distance in feet from the source. (L.R.Q.)

FOOTINGS. A footing is a **foundation** used to distribute concentrated loads in walls or **columns** over a suitable area of soil or subsoil. Footings must be spread wider than the base of a column or wall for a number of reasons. They must give stability by reducing the unit pressure below that at which there might be local settlement along one side of the foundation. They must be thick enough to resist the punching shear of the column, and they must not flare so rapidly as to cause them to be weak in bending. Footing for walls, columns, etc. may be very conveniently and economically made of reinforced **concrete.** Except for very heavy loads, the footing slab is usually square or rectangular and of constant thickness. Design is usually made by semi-rational rules and formulae since the distribution of stress in such a structural unit is very complex. For very heavy column loads the footing is usually made in the form



Section—Spread Footing

of a truncated pyramid or preferably in a series of steps giving the "stepped footing." The latter type, illustrated in the figure, predominates, due to the ease with which forms may be constructed. In case the soil is so weak as to require an extremely wide footing, a steel **I-beam** grillage is incorporated in the footing. (F.T.M., E.W.S.)

FOOT POUND. Work.

FOOTWALL. Fault.

FORAMEN. An opening, especially in bone, through which other structures pass, such as nerves and blood vessels. (A.W.L.)

FORAMINIFERA. **Sarcodina; Invertebrate Paleontology.**

FORBES LOG. **Patent Log.**

FORBIDDEN TRANSITIONS. **Combination Principle.**

FORCE. Our basic concept of force is that afforded by the muscular sense. We exert muscular effort upon objects and thereby produce certain effects; and when we observe similar effects produced by other means, we attribute them to the action of forces, whatever the ultimate nature of those agencies may be. Thus, if a strip of steel is clamped at one end and pulled sidewise at the other with the finger, it bends. A magnet placed near it will cause it to bend in the same way; and though we may know nothing of the nature of magnetic influence, we say that a force is acting upon the steel spring.

Force produces other effects than elastic deformation. **Newton's Laws of Dynamics** deal primarily with forces, and the first of his Laws points out that force, and force alone, can alter the motion of free bodies. He also recognized that the earth exerts forces upon all bodies near it, the measure of which is the weight of those bodies. Other examples are magnetic and electric interaction, cohesion, adhesion, and chemical affinity.

With so many objective manifestations, it becomes necessary to choose a suitable standard measure of force from among them. Elastic deformation and the sustaining of weight are actually used in familiar methods of force measurement, as with the spring balance and certain engineering testing machines. But these methods have the disadvantage of variability with time or place, since springs lose their elasticity and the intensity of gravity varies with latitude and altitude. A plan better adapted to accuracy is to accept Newton's second Law as the definition of our standard measure of force, and to agree that forces are to be considered proportional to the rates at which they cause free bodies to change their motion.

This "inertia measure" gives rise to a system of absolute units of force, recognized by Gauss and sometimes therefore called Gaussian units. Such units, for example, are the **dyne**, the **Newton**, and the less used poundal, each of which is defined as the force required to give some specified unit of mass a specified (linear) acceleration.

Expressed in these absolute units, the force required to give to the mass m an acceleration a is $f = m \cdot a$; this being the mathematical expression of the second Law in terms of these units. Thus, if a force of 1000 poundals were to be exerted upon a free mass of 500 lbs., the acceleration would be $a = f/m = 1000$ poundals/500 lbs. = 2 ft. per sec. per sec.

While the dyne and the poundal are thus conveniently related to problems of motion, and are invariable, they are awkward to apply in actual measurement. The units ordinarily used in practical engineering are gravitational, viz., simply the weights of suitable units of mass. Thus, tension in a truss rod is customarily expressed in pounds, the pound of force being the pull of gravity on a standard pound mass. While this pull differs by about one part in 160 between equator and poles, the variation with latitude is not important in engineering; and since gravitational units are so easily applied by simply balancing the unknown force against weights, they are in more general use than any others.

The **equilibrium of forces** is the subject-matter of **statics**, while the relation of forces to the motions of bodies is treated under **kinetics**; forces are also involved in the discussion of **work** and of **power**. (L.D.W.)

FORCE FIT. **Fit.**

FORCE PUMP. **Air Pumps; Pumps.**

FORCIPULATA. **Asteroidea.**

FORECAST OF WEATHER. **Weather Forecasts.**

FORE-SET BEDS. **Delta.**

FORESIGHT. **Differential.**

FORE-SKIN. The prepuce, a prolongation of the skin of the shaft of the **penis** or **clitoris**, covering the head of either of these organs. It is this fold of skin that is removed by **circumcision**. (R.S.M.)

FOREST. **Wood.**

FORESTER. Mammalia, Marsupialia. The great gray **kangaroo**. (A.W.L.)

FORGING. The shaping of metal by hammering or cogging. Only the malleable metals may be worked successfully. While most metals may be shaped in the cold state, the application of heat increases plasticity and permits greater deformation with any given expenditure of energy.

In usual forging practice, heated billets or stock are used. Extremely large billets or ingots are heated in soaking pits which are usually fired with gas or oil fuel and which often are designed to utilize regenerative heating principles. Billets or blooms of smaller size are heated in open muffle furnaces fired with gas or oil.

Stock forged by hand is generally small and this may be heated in a forge. A forge is a hearth made from fire-clay, firebrick, or tamped sand so arranged that a fire of coal, coke, or charcoal may be built upon it. Air is supplied from a blower through tuyeres, or openings, suitably placed. A hood above the forge removes the products of combustion from the forge room. In using a forge, the piece to be worked is buried in the hot coals of the thick carbonaceous fuel.

Care must be exercised in the heating of all metals for forging. Metals that are heated too long at too high a temperature oxidize rapidly, forming an excessive amount of scale which not only wastes metal but also prevents the production of smooth surfaces. Temperatures may be measured with thermocouples or with optical pyrometers and standard practices may be developed to give uniform results for any forgeable metal. Some metals are susceptible to carburization, decarburization, attack by sulfur gases, and intergranular oxidation. Furnace atmospheres during heating may be controlled to prevent any of the before-mentioned conditions. High sulfur fuel is a common source of sulfur contamination.

Many metals and alloys forge best in a given temperature range and those that may be worked only in a very narrow range of temperature are generally considered the most difficult to forge because this characteristic requires frequent reheating if the total deformation is great.

In addition to fabricating an identified shape, the operation of forging improves the quality of metals. The coarse crystals of metal resulting from solidification in an ingot mold are kneaded and refined. Blow holes and layers of slag are consolidated and usually welded together. This results in a more ductile and stronger product than cast metal with much greater resistance to shock and to fatigue stresses. Hammer forging imparts a higher degree of refinement on the surface of the work while pressed forgings exhibit better average quality throughout thick pieces.

Upsetting is the process of increasing the cross-section of stock at the expense of its length. Swaging or drawing-down operations increase length of stock at the ex-

pense of reduction in cross-section. Setting down is a localized swaging operation. Bending processes may be classified as angular or as curvilinear. Punching is an operation carried out to remove a slug of metal through shearing. Cutting-out is the process of cutting large holes by progressively using a hot chisel over a hole in the swage block. Saddening is a series of light shaping blows useful in preparing some metals for heavy forging operations.

Die blocks for power forging are made from carefully manufactured alloy steels. Such blocks must have the ability to withstand severe strains imposed by high pressures on hard metals. Long life with a minimum of impression wear is a prime requisite.

Power hammers are used for unit-production forging operations on work that cannot be feasibly hand-hammered, and also on comparatively small work where labor costs may be reduced by their use. There are two general types of hammers, steam or air hammers and trip and helve hammers. In the steam hammer, steam pressure is exerted on both faces of a vertically reciprocating piston, which is connected to the ram by a piston rod, to raise the ram and also to aid in striking the blow. The steam pressure on the downward stroke imparts additional velocity to the falling weight. The ram will therefore strike a blow whose full rating will be about double that of a gravity ram.

A trip hammer has a vertically reciprocating ram that is actuated by a toggle connection driven by a rotating shaft at the top of the hammer. The shaft is driven by a cone clutch which in turn is driven by a second shaft and pulley. The speed of the ram and the resultant effect of the blow are determined by the varying speed of the shaft. Trip hammers are built in sizes from 15 to 500 lbs.

Helve hammers are made in the same sizes as trip hammers and are used for similar classifications of work. The helve hammer consists of a horizontal wooden helve, pivoted at one end with a hammer at the other, and a cam or eccentric between the pivot and the hammer. The cam raises the hammer which falls and strikes a blow by the force of gravity. The action of a helve hammer is essentially that of a hand sledge since the wooden helve is somewhat elastic.

Light hammer blows are comparatively superficial in effect, while a heavy more slowly delivered blow penetrates and influences the material structure to a much greater extent. This effect is of particular importance in large forgings. Therefore, steam-actuated hydraulic presses are employed. Hydraulic presses for forging purposes range in size from 200 to 15,000 tons.

Drop forging is the process of shaping hot metal by forcing it into die cavities by the application of sudden blows. There are two principal forms of drop hammers that are used for drop-forging operations—the steam hammer and the board drop. The operation of the steam hammer has been described previously; the board drop has a hammer or ram fastened to maple boards whose upper ends pass between two rotating rolls. When the rolls are moved towards each other, they lift the board. At the top of the stroke the rolls automatically separate and release the board, permitting the ram to drop and strike the blow. Most board drop hammers are equipped with a device for changing the length of fall and consequently the force of the blow. Forging presses, in which the vertical ram is actuated by a pitman operated by an eccentric, are used for impact extrusion, hot forging, and hot and cold coining operations. These presses are available in capacities up to 2000 tons.

Forging rolls are often used for the breakdown operations preliminary to drop forging, and for reducing short thick sections to long slender sections. Their action is similar to that of rolling mills, but the forging rolls make use of only a portion of a revolution to reduce the stock; the remainder of the roll has a blank clearance space for the ends of the stock that are to be left full size. The operator stands at the back or emerging side of the rolls, and when the clearance space appears, he places the work into this space. When the reducing portion of the rolls comes in contact with the work, it reduces the stock and ejects it from the rolls towards the operator. At the next open portion of a revolution of the rolls, the stock is again inserted for a second reducing operation. By this method only as much of the length of stock is reduced in area as is required. Forging rolls contain a number of grooves, depending upon the number of passes required.

Machine forging, as distinguished from drop forging, is an upsetting or heading process applied to forgings made from bar stock. A forging machine consists essentially of three dies: a movable die opposed to a stationary die (the two are used for gripping the bar stock) and a third or header die which moves in a plane parallel to the parting surface between the clamping dies, and handles the major portion of the work of forging. The die operation is automatic and is controlled by a treadle-operated clutch. The operator inserts the bar, steps on the treadle and the movable die closes, gripping the bar. The header die moves forward to perform its operation and returns to starting position, and the movable die opens, completing the cycle. The operator then moves the bar to the next die cavity and again steps on the treadle to begin the next cycle. (H.C.H., M. E. CARRUTHERS, AMERICAN ROLLING MILLS CO.)

FORK-TAIL. Aves, Passeriformes. Indian birds related to the European **chats.** (A.W.L.)

FORM FACTOR. Form factor is a means for describing the shape of an **alternating-current** wave. The strength of a.c. constantly varies in magnitude and direction. The effective value of a.c. is equal to the d.c. which will produce the same heating effect as the a-c wave. The average value of an a.c. is that value which, multiplied by the length of time consumed in a cycle, would result in the same number of ampere-seconds as are included under the actual curve showing the wave form. The form factor is the ratio of the effective value of a current to its average value, and is smaller for a flat wave than for a peaked wave. (F.T.M., L.R.Q.)

FORMALDEHYDE. Formaldehyde (HCHO) is a colorless, soluble gas, boiling point $-21°$ C., commonly encountered as a 40% solution in water ("formalin"), which frequently contains **methyl alcohol,** up to about 20%, to increase the stability of the solution especially when exposed to winter temperatures. Both the gas and the solution have a pungent, irritating, characteristic odor, and the solution acts upon the skin to form a leather-like layer and frequently causes sores. Formaldehyde reacts with many chemicals in a marked manner, (1) with ammonio-silver nitrate (Tollen's solution), to form metallic silver, either as a black precipitate or as an adherent mirror film on glass, (2) with alkaline **cupric** solution (Fehling's solution), to form cuprous oxide, red to yellow precipitate, (3) with rosaniline (fuchsine, magenta) which has been decolorized by **sulfurous acid** (Schiff's solution), the pink color of rosaniline is restored, (4) with **sodium** hydroxide, yields methyl alcohol plus sodium formate, (5) with **ammonium** hydroxide, when evaporated, yields hexamethylene tetramine "urotropine" ($(CH_2)_6N_4$), white solid, melting point 263° C., (6) with **sodium** or **hydrogen peroxide** in sodium hydroxide, yields sodium formate, (7) with **manganese** dioxide and **sulfuric acid,** forms methylal, dimethoxymethane ($CH_2(OCH_3)_2$), colorless liquid, boiling point 42° C.

Formaldehyde gas, when cooled under certain conditions, yields trioxymethylene, metaformaldehyde ($(CH_2O)_3$); formaldehyde solution, when evaporated, upon standing, or upon being subjected to low temperatures, yields paraformaldehyde ($(CH_2O)_x$), white solid,

from which formaldehyde is regenerated upon heating; dilute formaldehyde, in the presence of calcium hydroxide solution, yields a mixture of sugars called formose from which fructose ($C_6H_{12}O_6$) has been prepared, suggesting the intermediate formation in nature of formaldehyde in the photosynthetic process of the conversion of carbon dioxide to sugars. Formaldehyde stands chemically between methyl alcohol on the one hand—to which it can be reduced—and formic acid on the other hand—to which it can be oxidized. Formaldehyde is made by passing methyl alcohol vapor mixed with air over a **catalyzer,** e.g., smooth copper wire gauze, at a dull red heat, and collecting the resulting solution. Formaldehyde is commonly detected by the Schiff test (above), and confirmed by the formation of a dimethyl derivative with a melting point of 189° C. Formaldehyde is extensively used (1) as an antiseptic, disinfectant, and insecticide, in the preservation of glue, in the preparation of anatomical specimens, in embalming fluids, in treatment of pests in enclosed spaces and on seeds before planting, (2) as a constituent, along with a **phenol,** of synthetic **plastics** and **resins,** (3) as a hardener, stabilizer or preservative in casein, starch, and sugar preparations, (4) as a reducing agent in gold and silver metallurgy, and in silvering mirrors. (R.K.S.)

FORMALIN. **Formaldehyde.**

FORMATION. A distinct lithologic unit which may be used in geologic mapping. The term formation is usually confined to **bedded** or **stratified rocks,** including lava flows and volcanic **ejectamenta.** (R.M.F.)

FORMER. **Forging.**

FORMIC ACID AND FORMATES. Formic acid ($HCHO_2$ or $HCOOH$) is a colorless liquid, melting point 8.4° C., boiling point 100.5° C., miscible with water, alcohol or ether in all proportions. Formic acid solution reacts (1) with **hydroxides, oxides, carbonates,** to form formates, e.g., **sodium** formate, **calcium** formate, and with **alcohols** to form **esters,** (2) with silver of ammonio-silver nitrate to form metallic silver, (3) with **ferric** formate solution, upon heating, to form red precipitate of basic ferric formate, (4) with **mercuric** chloride solution to form mercurous chloride, white precipitate, (5) with **permanganate** (in the presence of dilute **sulfuric acid**) to form carbon dioxide and manganous salt solution. Formic acid causes painful wounds when it comes in contact with the skin. At 160° C., formic acid yields carbon dioxide plus hydrogen. When sodium formate is heated in vacuum at 300° C., hydrogen gas and sodium oxalate are formed. With concentrated sulfuric acid heated, sodium formate, or other formate, or formic acid, yields carbon monoxide gas plus water. Sodium formate is made by heating sodium hydroxide and carbon monoxide under pressure at 210° C. The following are representative esters of formic acid:

		Boiling Point, °C.
Methyl formate	$HCOOCH_3$	32
Ethyl formate	$HCOOC_2H_5$	54
Glycol diformate	$HCOOCH_2CH_2OOCH$	174
Ethyl orthoformate	$HC(OC_2H_5)_3$	146

Formic acid may be obtained (1) from some natural products, e.g., the juice of the hairs of the stinging nettle plant, the juice of the giant nettle tree, the juice of ants and some caterpillars, (2) from sodium formate solution by addition of sodium hydrogen sulfate or dilute sulfuric acid, and then distilling, preferably in vacuum, (3) by reaction of **oxalic acid** and **glycerol** at 100° to 110° C., (4) from **lead** formate solid and **hydrogen sulfide** at 100° C. yielding anhydrous formic acid. Formic acid is used (1) in the textile and leather industries, (2) in reaction with glycerol at 220° C. to form allyl **alcohol,** (3) in the preparation of metallic formates, and **esters.** (R.K.S.)

FORMING. Fabrication of sheet and plate primarily by bending rather than by tension as in **drawing** or **stamping.** (R.H.H.)

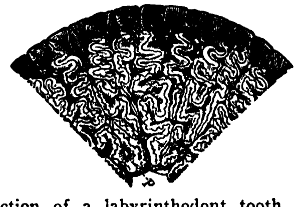
FORMULAE, CHEMICAL. **Chemical Composition.**

FORWARD BEARING. **Bearing.**

FORWARD VOLTAGE. This is the voltage applied across an electron **tube** in a direction causing the **anode** to be positive and the **cathode** negative. (L.R.Q.)

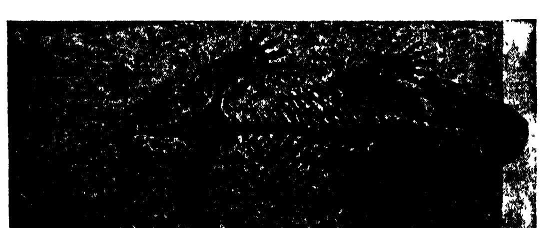
FOSSA. 1. An anatomical term indicating a depression or furrow. 2. Civet. A species found in Madagascar. *Cryptoprocta ferox.* (A.W.L.)

FOSSIL AMPHIBIA. The first or earliest evidence of an **amphibian** is a primitive footprint in formations of upper **Devonian** *age.* The footprint is of particular significance because it suggests a transition stage in the development of the primitive limb structure of the first terrestrial **vertebrates** from the pectoral fins and limb girdle of the air-breathing ganoids, which also occur in the Devonian. The first known skeletons of amphibia occur in formations of Devonian age. These earliest known amphibia are called Stegocephalia, because their heads are covered or "roofed" with thick dermal bones. In some species both the back and stomach were covered with bony plates or scales. Thus the earliest known amphibia (Stegocephalia) were armored as compared with most of their modern descendants. Other particularly significant anatomical features are (1) a third, or pineal, eye, (2) presence of a ring of plates around the two lateral eyes, (3) the arrangement of the dermal plates in the head, (4) conical teeth, showing an infolding of the dentine and enamel. This type of tooth structure is particularly characteristic of one group called *Labyrinthodonts.* All of the aforementioned features



Transverse section of a labyrinthodont tooth. (*After Owen from Norton's Elements of Geology, Ginn and Company.*)

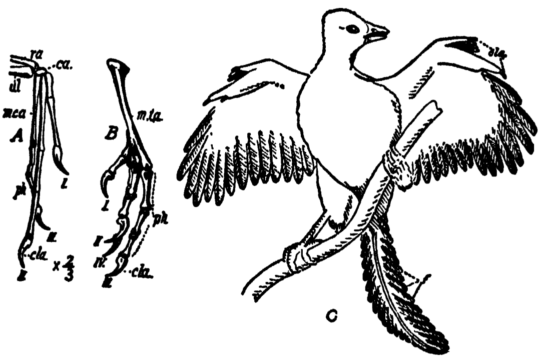
suggest ancestral relationship to the ganoid fishes. The fossil record of the amphibia is the poorest of all the terrestrial vertebrates. They are therefore not particularly valuable as index fossils, their place being taken by



A Pennsylvania amphibian (labyrinthodont), *Eryops.* This creature attained a length of 6 or 8 feet. (*American Museum of Natural History.*)

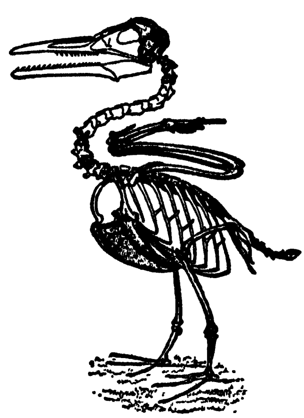
the **Mesozoic** reptiles and **Cenozoic** mammals. (See chart illustrating the geologic range of the vertebrates under the title **Vertebrate Paleontology.** (R.M.F.)

FOSSIL BIRDS. Probably one of the most famous fossils in the world is Archaeopteryx, or the flying reptile which had feathers. Fossil birds are rare, therefore it is all the more remarkable that this "missing link" between the reptiles and the birds should have been discovered as a natural lithograph in the fine-grained lithographic limestones of Upper Jurassic age at Solenhofen, Bavaria. Only two specimens of this genus are known. Archaeopteryx was about the size of a crow,



The earliest known bird, *Archeopteryx macrura*, from the Jurassic. *A*, right hand; *B*, right foot; *C*, restoration modified after Pycraft. (*Shimer's Introduction to the Study of Fossils, The Macmillan Co.*)

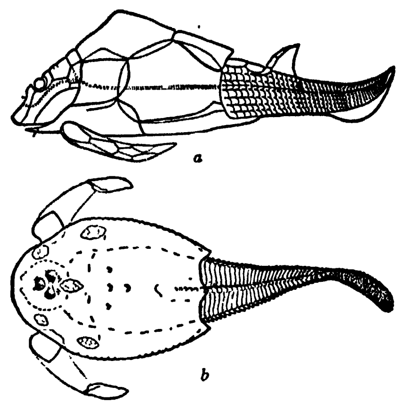
with the combined reptilian and bird-like claws upon each of the three fingers terminating the wings, and lateral arrangement of the feathers in the tail. There have been several theories as to the origin of Archaeopteryx. One is that it evolved from a small carnivorous bipedal **Triassic** dinosaur. Toward the close of the Mesozoic the birds evolved rapidly. Fossils from the **Cretaceous** show both flying and diving forms, such as *Ichthyornis*, shown in the accompanying illustration. The birds did



A Cretaceous toothed bird, *Ichthyornis victor*. Height, about 8 inches. (*After Marsh.*)

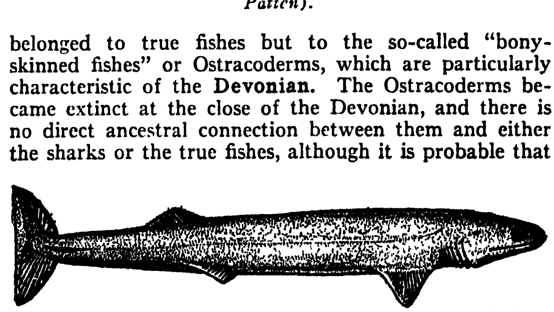
not lose their teeth until the **Tertiary.** It is also interesting to note that one of the largest known birds that ever lived, *Dinornis maximus* from New Zealand, stood 12′ high and has only recently become extinct. The nearest living relative of the ancestral bird (Archaeopteryx) appears to be the Hoactzin of the Amazon Valley. The embryonic history of this bird repeats many of the adult features of Archaeopteryx, and the young hoactzin still retains claws on its wings, but these claws disappear in the adult stage. As has been previously implied, birds do not make good index fossils primarily because of their rarity as fossils even in the later periods of the earth's history. (See chart illustrating the geologic range of the vertebrates listed under **Vertebrate Paleontology.**) (R.M.F.)

FOSSIL FISH. The earliest fish may be represented by a "fish-scale" in the **Cambrian.** Problematical fish remains have also been found in the **Ordovician,** and small fin spines in the lower **Silurian.** A famous upper Silurian occurrence is the Ludlow bone bed of England. Probably none of the aforementioned bones and scales



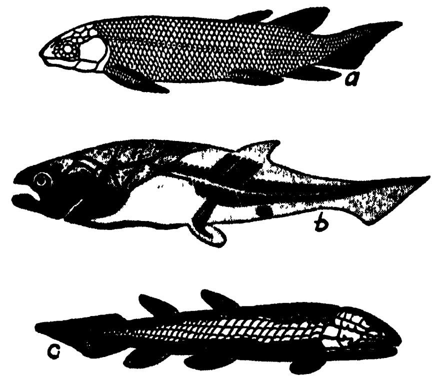
Devonian Ostracoderms; *a, Pterichthys testudinarius*, restored (*Dean after Woodward*); *b*, Tremataspis, restored (*after Patten*).

belonged to true fishes but to the so-called "bony-skinned fishes" or Ostracoderms, which are particularly characteristic of the **Devonian.** The Ostracoderms became extinct at the close of the Devonian, and there is no direct ancestral connection between them and either the sharks or the true fishes, although it is probable that



A Paleozoic (early Mississippian) Selachian or shark, *Cladoselache fyleri.* (*Restored by Dean.*)

all the types mentioned had a common ancestor. The Ostracoderms were armored with placoid bony plates or scales. They had no interior skeleton, and certain types such as Pteraspis and Cephalispis were probably adapted to bottom-feeding in relatively quiet marine waters. Other types such as Bothriolepis and Pterichthys prob-



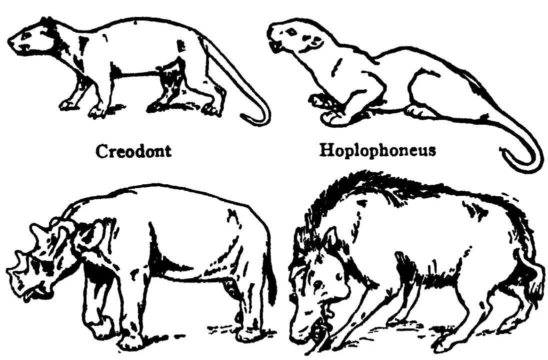
Devonian fishes: *a*, dipnoan. *Dipterus valenciennesi* (*restored by Traquair*); *b*, arthrodiran, *Coccosteus decipiens* (*restored by Woodward*); *c*, ganoid, *Osteolepis* (*restored by Nicholson*).

ably frequented fresh-water ponds and lakes. The earliest known sharks occur in the late Silurian or Devonian, and the true fishes (**Pisces,** or bony fishes) complete one phase of their development during the upper **Paleozoic** with a decline during the early **Mesozoic.** The **Cenozoic** has seen the gradual increase of a new phase

with rapid and continuous expansion in diversity of form and adaptability during the late **Tertiary** and **Quaternary.** One of the most interesting groups of the fossil fishes are the **Dipnoi,** or lung fishes. The ganoids first appear in the Devonian and are probably closely related to the progenitors of the first terrestrial vertebrates. The structure of the pectoral fins foreshadows a primitive limb and foot. The arrangement of the bones in the head is somewhat similar to that in the earliest known **Amphibia** (Stegocephalians) also, a peculiar ring of bony plates around the eye, and the conical teeth of infolded dentine and enamel are similar to those of the earliest known Amphibians. (See chart on geologic range of the vertebrates under the title **Fossil Vertebrates.**) (R.M.F.)

FOSSIL MAMMALS. The paleontological record suggests that the mammals have evolved from the reptiles through a common ancestor with the Theriodontia (beast-toothed reptile) of the **Permian.** The rise of the reptilian mammals began as early as the **Triassic,** as disclosed by small lower jaws and teeth. These animals have been classified as multituberculates, so named because the teeth have coned or tuberculated surfaces. Living descendants of this primitive group include the spiny ant-eater, **Echidna (duck bill)** and the duck-billed mole, *Ornythorynchus,* now living in Australia. Small mammalian jaws similar to those of insectivores have also been discovered in the **Cretaceous.** Most of the **Mesozoic** pro-mammals were probably egg-laying, relatively small in size and quite unable to usurp the place of the great host of **dinosaurs** which had become adapted to all types of environment. Following the extinction of the dinosaurs at the close of the Mesozoic, the mammals rapidly evolved soon after the beginning of the **Cenozoic,** and especially from the **Oligocene** on.

The reptile-like mammals of the Mesozoic, which may be termed pro-mammals, were followed by the archaic mammals of the **Paleocene.** Nearly all of the forms were small, primitive and generalized, with long and heavy tails, short limbs and five digits on each foot. The principal flesh-eaters were the creodonts, and of the modern orders of mammals only the **insectivores** and **marsupials** are present. The ancestors of the first mod-



Uintatherium Archaeotherium
(*Field, Outline of Geology, Barnes & Noble.*)

ern mammals such as Eohippus (a diminutive **horse**), cursorial **rhinoceroses,** the creodonts and other earlier archaic forms are also present but are rapidly being replaced by more active and intelligent types. One of the large-hoofed giant herbivores or hippopotamus-like forms is called uintatherium. The mammals first begin to take on a modern aspect in the Oligocene, including a large number of forms which grazed on the open plains. The true carnivores have replaced the creodonts, including Hoplophoneus, ancestor of the saber-toothed cats. The remainder of the Cenozoic saw the gradual evolution of the modern mammals. Among the many modern forms the paleontological record of the elephant has been remarkably well worked out as shown by the accompanying charts. Because of the strongly marked climatic zones of the **Pleistocene,** as well as the glacial

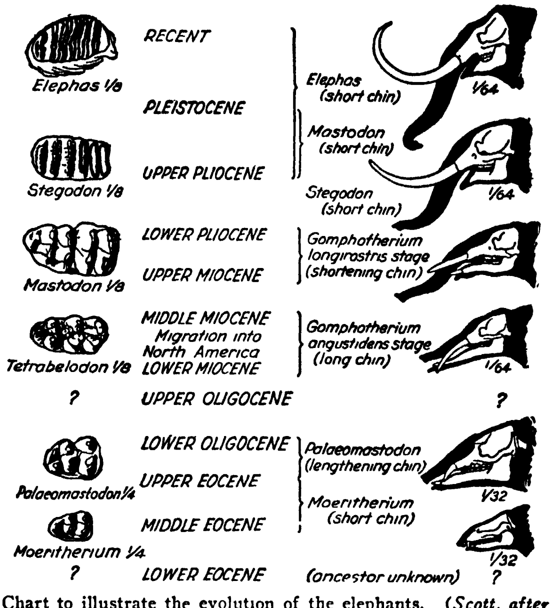


Chart to illustrate the evolution of the elephants. (*Scott, after Lull, modified by Sinclair. The Macmillan Co*)

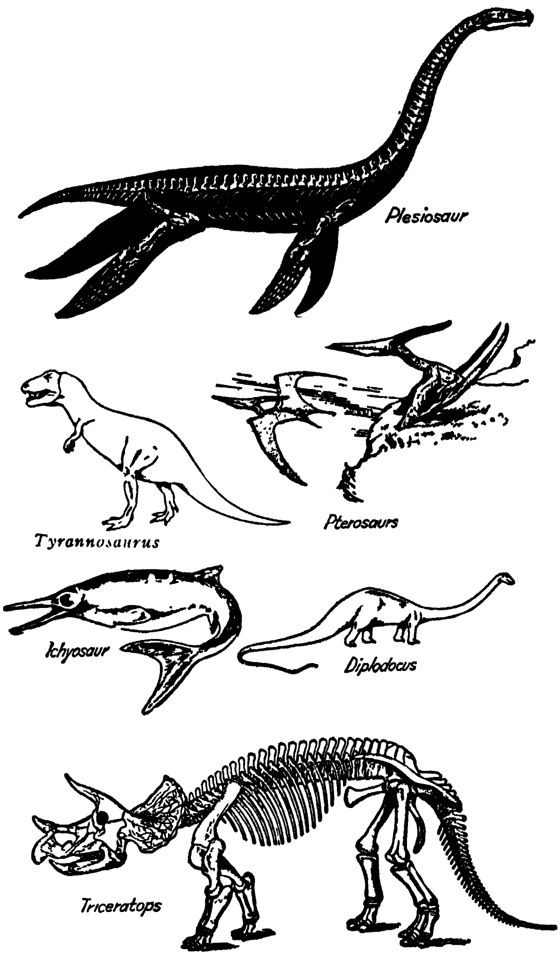
and interglacial cycles within the areas subjected to continental glaciation, the end of the Cenozoic is remarkable for the large number of mammals as well as the origin and evolution of man. (See **Paleontology of Man.**) (R.M.F.)

FOSSIL MAN. **Paleontology of Man.**

FOSSIL PLANTS. **Paleobotany.**

FOSSIL REPTILES. The first or earliest evidence of reptiles is in the **Pennsylvanian.** Most of these reptiles were sluggish animals, probably not much more active than their amphibian progenitors, and equally adapted to both water and land. Some forms, however, such as the Pelycosaurs, or sail-backed lizards, had a great dorsal "fin," and thus appear to have been highly specialized. Most of the forms were distinctly lizard-like in appearance. The cotylosauria were the most primitive of the **Paleozoic** reptiles showing many of the ancestral **Stegocephalian** characters. Another and particularly interesting group of reptiles which lived during the **Permian** and **Triassic** periods are the Theriodontia. Fossil skeletons of these are found only in South Africa. Although these animals were reptilian, their teeth show a differentiation into incisors, canines, and molars, a decidedly mammalian characteristic. Because of this and certain other anatomical features the Theriodontia are considered by some paleontologists as the "missing link" between the reptiles and the mammals. The reptiles reached their all-time development during the **Mesozoic,** thus this era has been termed the age of reptiles. Among the Mesozoic reptiles the great group of the **Dinosaurs** command particular attention because they varied in size from the smallest bird-like creatures to huge forms, both carnivorous and herbivorous, which rival the mightiest animals that ever lived. The evolutionary vitality was particularly well expressed in the extreme adaptation of body forms to all types of habitat as outlined in the chart on page 605. The dinosaurs became extinct at the close of the Mesozoic, and the modern



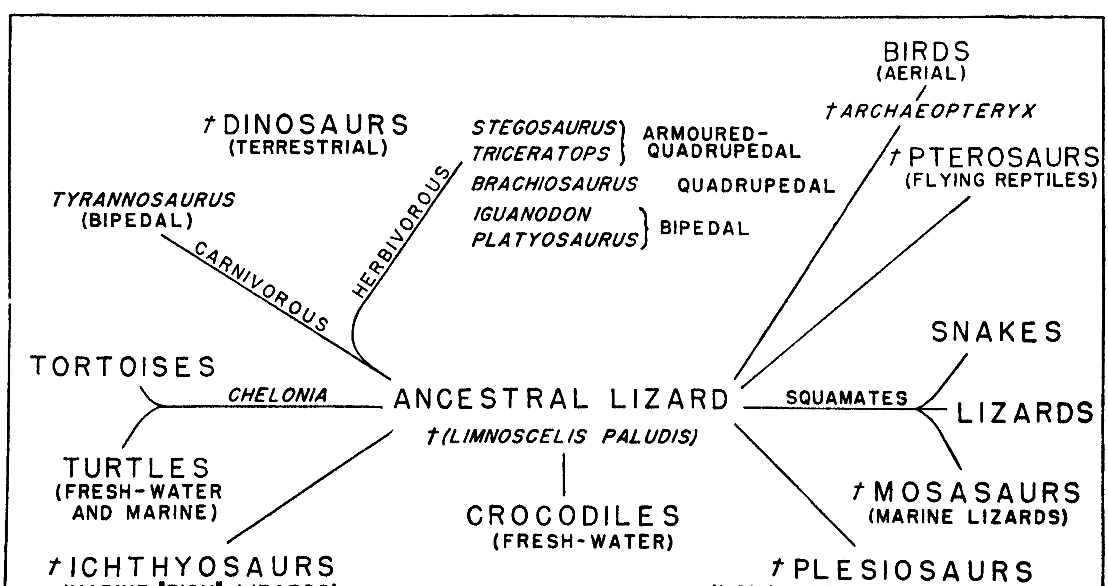
Fossil reptiles.
(Field, Outline of Geology, Barnes & Noble.)

reptiles, such as the lizards, snakes, and turtles, are but a remnant of the great record of reptilian evolution. (R.M.F.)

FOUCAULT PENDULUM. In 1851 Foucault performed his celebrated **pendulum** experiment at Paris, designed to give physical proof that the earth is in rotation about an axis. The pendulum, consisting of a very large iron ball suspended by a steel wire over 200′ long, was suspended from the center of the dome of the Pantheon. Great care was exercised in the support for the wire so that no external forces should be effective at this point other than a vertical force to prevent the system from falling. On the floor, immediately under the pendulum, a layer of fine sand was placed so that the direction of the swing could be observed. The pendulum was started by drawing it to one side with a fine thread and, after the system was at rest, the thread was burned off, thus avoiding any lateral motion.

After such a pendulum is started swinging in one plane, it is soon observed that the plane of swing is apparently deviating slowly (in the clockwise direction in the northern hemisphere and the opposite in the southern). The rate at which the plane of swing deviates is equal to 15° per sidereal hour (c.f. **time**) multiplied by the **sine** of the **latitude**. Thus at the pole it would make a complete rotation in one sidereal day, while at the equator it would not rotate at all. At Paris (latitude 48° 50′ N.) the rate of deviation is about 11° 18′ per hour.

Foucault reasoned quite correctly that, in accordance with **Newton's Laws of Dynamics,** the direction in space of the plane of swing should not change unless the pendulum was acted upon by some external force other than that of gravitation and the counteracting force parallel to the direction of gravitation at the support. That the direction of the plane does apparently change can be accounted for only on the hypothesis that the earth is in rotation. Foucault's demonstration attracted wide scientific and popular attention and was accepted as a conclusive proof that the earth does rotate upon an axis, a fact which was not universally accepted at that time. (W.K.G., L.D.W.)



ADAPTIVE EVOLUTION OF THE REPTILES
(Field, Laboratory Manual, Princeton University Press.)

† = extinct.

FOUNDATIONS. The structural foundation is that part of a structure which transmits the loads to the supporting material. In the design of a foundation it is essential that the settlement shall be reduced to a minimum and that this settlement shall be uniform at all points. The first requirement may be fulfilled by providing a **bearing** area which is large enough to reduce the bearing pressure on the underlying material to a safe value. In the case of soils having low bearing values **pile** foundations can be used to reduce settlement. The second requirement may be secured by designing the foundations so that the **resultant** of the vertical **loads** passes through the **center of gravity** of the foundation. If the material under the foundation is structurally sound rock, having a bearing value within safe limits, there will be no appreciable settlement of the structures; but there is bound to be settlement in structures whose supporting medium is earth since it is a compressible material.

A floating foundation is a reinforced **concrete** mat which covers the entire area under the structure and transfers the loads to the supporting soil. This mat may be a thick slab or a system of beams and thinner slabs. Floating foundations are generally used for soils having very low bearing values.

For different types of foundation refer to **Caisson, Footings, Grillage, Pier** and **Pile.**

The machine foundation performs more than a simple bearing function. It must:

1. Distribute the weight of the machine, the machine bedplate, and its own weight over a safe subsoil area. If heavy unbalanced vertical kinetic forces (see **Mechanics**) are produced by the machine, they should be added to the dead weight and the bearing power of the soil must be well in excess of these vertical forces.

2. Provide sufficient **mass** to absorb machine vibration. Satisfactory foundation weight for this factor is not readily calculable. The accompanying table is given to provide an indication of minimum weights.

WEIGHT OF ENGINE FOUNDATIONS PER BRAKE HORSEPOWER

Prime Mover	Single Cylinder	Multi-Cylinder
Gas engine....	2500 lbs.	1600 lbs.
Diesel engine...	2000 lbs.	1250 lbs.
Steam engine...	700 lbs.	500 lbs
Steam turbine..	Not to exceed permissible deflection as stated by turbine manufacturer.	

3. Be rigid enough to prevent undue deflection of any part of the machine bedplate.

Machine foundations are usually made of concrete and unless an unyielding foundation soil is available, the concrete at the bottom of the foundation is subjected to **tension.** Since this is generally the case, the heavy foundation should have reinforcement near the bottom.

Large turbine (see **Steam Turbine**) foundations are not required to contain foundation masses comparable with those necessary for similar reciprocating units. Still, the necessity of providing space beneath the turbo-generator for condenser, pumps, generator, air cleaner, or cooler, and sometimes the throttle lead, materially complicates the design of the turbine foundation. This foundation does not carry the turbine upon a heavy bedplate and hence a study of the foundation **deflections** is all important. No two foundations are alike. Reinforced concrete and structural steel foundations each have their advocates, but any installation should be figured upon a basis of comparable costs of the two types, because each is suited to a particular field of utility and economy. The concrete base gives more rigidity to the turbine, but it is claimed for steel that its flexibility is an advantage in large units since it prevents distortive bowing of the shaft and attendant difficulties. The concrete foundation will require less maintenance; the steel type yields more available space below the unit.

When bringing a machine into alignment on its foundation, shims or sole plates are placed beneath the frame or bedplate and adjusted until the alignment is level in two directions. A spirit level can be used when aligning small machines, but the engineer's level is best for all classes of work. After alignment is secured, an earth dam is built around the top edge of the foundation. **Grout** is floated or forced under the bedplate until it is flush with the top or bottom surface. (C.W.C., F.T.M.)

FOUNDRY. Casting.

FOUR-CYCLE. An abbreviated expression for four-stroke cycle. The four-stroke cycle is one upon which either the **Otto** or **Diesel** types of **internal combustion engines** may operate, since it describes, not **thermodynamic** aspects of a cycle, but rather the sequence by which the cylinder is charged and exhausted The four-stroke cycle is described as follows. Beginning with a suction or induction stroke, the **cylinder** is filled with a fresh charge by the outward motion of the **piston.** Next, on the return motion, this charge is trapped in the cylinder by closure of all **valves** leading to and from the cylinder, and is thereby compressed. On the next outward stroke, the power stroke, the fuel is burned or exploded to the accompaniment of energy liberation, a great deal of which is made usefully available on the power stroke. The final, or fourth, stroke is a return stroke, or exhaust stroke, during which the contents of the cylinder are exhausted through a port opened by an exhaust valve. Thus the four strokes are suction, compression, power, and exhaust. During the suction stroke, an inlet valve is open, during the exhaust stroke, an exhaust valve is open. The advantage of the four-cycle principle is that it gives a full stroke for induction of the fresh charge, and another full stroke for scavenging of the burned gas. In this way it promotes high **volumetric efficiency.** A disadvantage of the four-cycle principle is the intermittent delivery of power. This contributes to making the four-cycle engine bulky in comparison with the two-cycle, but by employing multi-cylindered engines a steady flow of power may be secured through overlapping of power strokes. (F.T.M.)

FOURIER'S LAW. Heat Transfer.

FOURIER SERIES. An infinite series of the type

$$\tfrac{1}{2}a_0 + a_1 \cos x + a_2 \cos 2x + a_3 \cos 3x + \cdots + b_1 \sin x + b_2 \sin 2x + b_3 \sin 3x + \cdots,$$

or, more briefly written,

$$\tfrac{1}{2}a_0 + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx),$$

where the coefficients a_n and b_n are independent of x, is called a trigonometric series.

If we assume the possibility of expanding any arbitrary function $f(x)$ in a series of this form, and if we assume the uniform convergence of the series, the coefficients a_n and b_n are found to be given in terms of $f(x)$ by the formulae:

$$a_n = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x) \cos nx\, dx, \quad b_n = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x) \sin nx\, dx.$$

A trigonometric series whose coefficients are given by these formulae is often called the Fourier series of $f(x)$. The problem still remains of investigating the convergence of this series and the question as to whether the series represents the function.

A fundamental theorem concerning Fourier's series is the following Fourier's theorem:

Any single-valued function $f(x)$, which is continuous except possibly for a finite number of finite discontinuities in the interval $-\pi$ to π, and which has only a finite number of maxima and minima in that interval, may be represented by a Fourier series

$$f(x) = \tfrac{1}{2}a_0 + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx),$$

where the coefficients a_n and b_n are given by the previous formulae in terms of integrals. (See **Harmonic Analysis; Vibration and Waves.**) (L.L.S.)

FOWL. Aves, Galliformes. Birds of the domesticated varieties. (A.W.L.)

FOWLERITE. Rhodonite.

FOX. Mammalia, Carnivora. **Vulpes.** Members of the **dog** family (Canidae) of moderate size and slender build, with a sharp muzzle, long bushy tail, and unusually large ears. Most species inhabit the northern hemisphere but a few are found in Africa with the closely related fennecs.

The fur of the fox is valuable. The excellent market for that of the silver fox has led to extensive breeding of these animals in captivity.

North America has several species of red foxes and several of gray. The silver fox is a variety of a red fox, and kit fox is a related species. (A.W.L.)

FOXGLOVE. Figwort.

FRACTIONAL EQUATIONS. An **algebraic equation** in which one or both sides are rational **fractional functions** is called a rational fractional equation.

Such an equation may in general be solved by clearing the equation of fractions by multiplying its terms by the **least common multiple** of the denominators of its fractions, thus reducing it to a **polynomial equation** (frequently of first or second degree).

In this method of solution, by clearing of fractions, **extraneous roots** may arise, so that the solution of each fractional equation should be checked by substituting in the original equation, and all values not satisfying this equation should be rejected. (L.L.S.)

FRACTIONAL FUNCTION. A rational fractional function is a **rational function** which is not a **polynomial function** (rational integral function); it involves the variable in a denominator of a **fraction.**

A rational fractional function can be expressed as a quotient of two polynomials. (L.L.S.)

FRACTIONS. A fraction is an indicated **quotient** of two numbers or two expressions. The dividend and divisor of the quotient are called respectively the numerator and denominator of the fraction.

A fundamental principle for operations with fractions is the following: The numerator and denominator of a fraction may both be multiplied or divided by the same number without changing the value of the fraction:

$$\frac{a}{b} = \frac{ma}{mb}.$$

A fraction is said to be in its lowest terms when its numerator and denominator have no common factor. A fraction can be reduced to its lowest terms by dividing the numerator and denominator by their **highest common factor.**

The signs of both numerator and denominator of a fraction may be changed without changing the value of the fraction. If the sign of either numerator or denominator is changed, the sign of the fraction is changed. Thus:

$$\frac{-a}{-b} = \frac{a}{b'} \quad \frac{-a}{b} = \frac{a}{-b} = -\frac{a}{b}.$$

Two or more fractions may be changed to equivalent fractions with a common denominator by multiplying the numerator and denominator of each fraction by the quotient obtained by dividing the **least common multiple** of all the denominators by the denominator of that fraction.

The sum (or difference) of two fractions with a common denominator is a fraction with the common denominator and whose numerator is the sum (or difference) of the given numerators:

$$\frac{a}{c} \pm \frac{b}{c} = \frac{a \pm b}{c}.$$

To add (or subtract) any two fractions (with different denominators), change each fraction to equivalent fractions with a common denominator (usually the least common denominator), and then combine them by the preceding rule:

$$\frac{a}{b} \pm \frac{c}{d} = \frac{ad}{bd} \pm \frac{bc}{bd} = \frac{ad \pm bc}{bd}.$$

The product of two fractions is a fraction whose numerator is the product of the numerators of the given fractions and whose denominator is the product of their denominators:

$$\frac{a}{b} \cdot \frac{c}{d} = \frac{a \cdot c}{b \cdot d}.$$

To divide one fraction by another, invert the divisor fraction and multiply the dividend by this inverted fraction:

$$\frac{a}{b} \div \frac{c}{d} = \frac{a}{b} \cdot \frac{d}{c} = \frac{a \cdot d}{b \cdot c}.$$

(L.L.S.)

FRACTURE. In medicine, a fracture is a breaking of any solid structure or organ of the body. Commonly, the term is used to describe a broken bone. Fractures are classified as to whether they are transverse or oblique; and comminuted, simple, compound, depressed, greenstick, or impacted. In a comminuted fracture, the bone is splintered into several fragments at the site of injury. In contrast to a simple one, a compound fracture is one in which the ends of the broken bone project through the skin; because of the possibility of bacterial infection in such an open wound, a compound fracture is always serious. A depressed fracture is a fracture of the skull in which a portion of the bone is pushed inward. The term greenstick is used when the break is in the shaft but does not extend all the way through the bone. Such a break is associated with bending and occurs only in children. In an impacted fracture one fragment is driven or jammed into the other.

Two of the commonest fractures are the so-called Colles' and Potts' fractures. A Colles' fracture is a break through the radius at the wrist; it occurs most frequently following a fall on the outstretched hand. In a Potts' fracture, the break is through the tibia and fibula at the ankle.

The treatment of fractures is directed toward the restoration of the normal anatomy and function of the part. In the immediate treatment of compound fractures, experiences in World War II have shown that debridement plus **penicillin** applied directly into the open wound is effective in preventing infection and reducing mortality. If there is displacement of bony fragments, they may be brought into alignment by closed reduction, i.e., manipulation or, if necessary, by open reduction, an operative procedure. Traction is used in certain instances to pull the bones into position and to maintain

them so until healing takes place. Fixation may also be achieved by the application of a cast. Complications delayed union, and nonunion.

In mineralogy, fracture is the property of minerals to break with curved or uneven surface. When a mineral has three planes of cleavage it has no fracture. Some minerals, such as **quartz**, have no well-defined planes of cleavage, but may be distinguished by their fracture, such as conchoidal (shell-like), splintery, etc. (R.S.M., D.M.H., R.M.F.)

FRAME, TELEPHONE. In order to provide the necessary flexibility in the use of telephone lines, numbers, and switchboard equipment a system of cross connections is used. The lines terminate on one side of a rack structure, known as the main distributing frame, and the switchboard wires corresponding to the telephone numbers terminate on the other. Flexible cross connections which may be changed at will connect the two. Another frame, the intermediate distributing frame, is used to make the system still more flexible by having the wires from the answering jacks of the switchboard terminate on it. (L.R.Q.)

FRAMED STRUCTURE. A framed structure is a group of structural members (**tension, compression** or flexural members) which are joined together in the form of triangles or rectangles in order to support given **loads** and distribute them to the supports in a definite manner. **Space frames, rigid frames** and **trusses** are all framed structures. (C.W.C.)

FRANCOLIN. Aves, Galliformes. Birds (**Aves**) of Africa and the Oriental region, related to the partridges. (A.W.L.)

FRANGIPANGI. *Plumeria acutifolia.* Apocynaceae. This is a shrub or small tree native to Mexico and Central America, which is often cultivated for the beauty and fragrance of its flowers. The plant has but few, rather coarse, branches. Its deciduous leaves are thick, smooth, and oblong to ovate in shape; in length they vary from 5–15″. The flowers, which often appear when the plants are leafless, are showy, and borne in terminal **cymes**. The flowers are red and extremely fragrant, and much used for decorative purposes. Several other species of *Plumeria* are known, some of which yield woods of some economic value. (R.M.W.)

FRANKLINITE. The mineral franklinite is a **zinc-iron-manganese** mineral whose formula may be written $(Fe, Mn, Zn)(FeO_2)_2$, but the composition varies considerably, in respect to the amounts of the several metals that may be present. Its isometric crystals have an **octahedral** habit; it may be coarse or finely granular or compact. It shows a parting parallel to the octahedron; fracture, uneven; brittle; hardness, 5.5–6.5; specific gravity, 5–5.2; luster, usually metallic, occasionally dull; color, black; streak, brown to black; opaque; may be slightly magnetic. Only in one place in the world does franklinite occur in quantity, at Franklin Furnace, New Jersey, from whence it was named. Here there are two bodies of this mineral, which is used as a zinc ore, about 3 miles distant from each other. The franklinite is found in pre-**Cambrian** limestones that are associated with **gneisses** believed to be of igneous origin and responsible for the mineralization. Associated minerals are **willemite,** zinc, silicate, and **zincite,** zinc oxide. Franklinite has been found at Eibach, Germany, in cubic crystals. (E.S.C.S.)

FRASCH PROCESS. Sulfur.

FRAUNHOFER LINES. The dark lines constituting the **absorption spectrum** exhibited by sunlight are frequently called the Fraunhofer lines. There are thousands of these lines, of which Fraunhofer, early in the 19th century, first observed the most prominent. To these particular lines he assigned letters for reference purposes. These lines, together with their origin and approximate wavelengths, are listed as follows:

A	Terrestrial oxygen	7594 A	(extreme red)
B	Terrestrial oxygen	6867 A	(red)
C	Hydrogen	6563 A	(red)
D_1	Sodium } doublet	5896 A	(yellow)
D_2	Sodium } doublet	5890 A	(yellow)
E	Iron	5270 A	(green)
F	Hydrogen	4861 A	(blue)
G	Iron and Calcium (group)	4308 A	(violet)
H	Calcium	3968 A	(extreme violet)

The lines of solar origin are due to absorption by gases and vapors in the solar **atmosphere.** (L.D.W.)

FREE FIT. Fit.

FREE GRID. This applies to the **grid** of an electron **tube** which has no electrical connection to it. Such a condition is highly undesirable, especially in vacuum tubes, since the grid will accumulate a charge which cannot leak off and which will alter the operation of the tube. If the charge remained fixed it would not be so serious, but the accumulated charge is very sensitive to external conductors, thus bringing the hand near a tube with a free grid will cause a redistribution of the electrons accumulated on the grid and cause the plate current to vary erratically. (L.R.Q.)

FREEMARTIN. A sterile cow, born as a twin of a bull. The sterility is due to the action of **hormones** produced by the male twin, which enter the circulation of the female in the **extraembryonic membranes.** (A.W.L.)

FREEZING POINT. The freezing point of a liquid is the temperature at which the solid form and the liquid form are in **equilibrium.** (See **States of Matter; Melting Point.**) (R.K.S.)

"FREON." A trademark for a group of halogenated hydrocarbons containing one or more fluorine atoms widely used as refrigerants and propellants "Freon-12" is dichlorodifluoromethane (CCl_2F_2), used in the "insect bomb" (see **DDT**). (R.K.S.)

FREQUENCY. In electricity, frequency is the number of complete alternations per second of an **alternating current.** Sixty cycles per second is becoming the standard frequency for a-c generation in the United States. Elsewhere 25 and 50 cycles per second have some vogue. In an **alternator,** the number of alternations per second of the output is the speed, in revolutions per second, multiplied by the number of poles. The number of poles in alternators is usually 2 or 4 for steam turbine-driven alternators, or 24, 26, 28, 30, 36, 48, or 60 in the case of engine-driven alternators. The formula for frequency, cycles per second, in terms of the rotative speed, rpm, and the number of electrical poles, is:

$$\text{Frequency} = \frac{\text{rpm} \times \text{number of poles}}{120}$$

In **acoustics,** the frequency represents the number of sound waves passing any point of the sound field per second. (See **Audio Frequency.**) In the case of **light** or other **electromagnetic radiation,** frequency may be expressed in this same way but is usually so enormous (500 million per second for yellow light) that wavelengths are ordinarily used instead. **Radio frequencies** are commonly given in thousands of cycles (kilocycles) or millions of cycles (megacycles) per second. (F.T.M.)

FREQUENCY ALLOCATION. This is the assigned carrier frequency of a radio transmitting station. Since radio signals must all use the same medium of transmission, the so-called ether, it is necessary to select the particular signal desired by tuning the **receiver.** Signals whose frequencies are too close together cannot be separated, i.e., they cause interference. To minimize this effect the frequencies of stations are assigned by the controlling governmental agency, Federal Communications Commission in the United States, and are required to maintain this assigned frequency within very close tolerances. Various types of service are assigned frequencies in bands set aside for their use by international agreement. (L.R.Q.)

FREQUENCY BAND. This is usually applied to a group of closely related frequencies, but common usage applies it in two slightly different senses. The first of these is synonymous with **channel,** meaning the band of frequencies associated with a carrier under **modulation.** The second usage means a group of different carrier frequencies all designated for the same purpose. In this sense there may be many frequency channels within the given band. Thus the standard broadcast band contains many broadcast channels, each having its carrier spaced 10 kc. from the next. In some types of radio service the only restriction on the carrier value is that it be kept within the allocated band. (L.R.Q.)

FREQUENCY CHANGER. Wherever there is to be an interchange of electrical energy between two systems which operate at different **frequencies,** the tie together must be through the medium of a frequency changer, since it is impossible to have two **alternators** electrically connected to the same line operating at different frequencies. The one operating at higher frequency will tend to motor the other, and take unto itself enough of the load so that through the slowing down of it, and the speeding up of the slower, their frequencies will coincide. The simplest plan for connection of two such systems, and the one usually employed, is to couple, mechanically, two rotating machines of the **synchronous motor** or **generator** type, which have, respectively, the correct number of electrical poles to permit one to operate at the frequency of one system, while the other is at the frequency of the other system, both, of course, having the same rotative speed. This is relatively simple in the case of the drawing of power, say, from a 60-cycle system to supply energy for 25-cycle use, but has serious disadvantages as a means of interconnecting two power systems of different frequency, each having considerable amount of generating equipment. Any slight alteration in the relative frequencies of these two systems results in heavy fluctuations of the frequency changer load, and necessitates the employment of extremely large and bulky frequency changers. Nevertheless, this is the system usually employed. Fortunately, the necessity for such frequency changing is rare in this country at the present time. (F.T.M.)

FREQUENCY CHANNEL. **Radio Communication; Carrier Frequency.**

FREQUENCY DEVIATION. In amplitude-modulated or continuous-wave radio transmission the frequency deviation means the amount by which the carrier varies from its assigned value. This must be kept within close limits, for broadcast stations at the present time within ± 20 cycles. The deviation is the result of many factors, some of which are easily controlled while others are difficult. Since the **oscillator** is the frequency controlling part of the **transmitter** its frequency must be held to the proper tolerances. High Q, low-temperature effects, light load and stable voltages are among the things which must be realized to maintain a stable frequency. In frequency or phase **modulation** the frequency deviation is the amount by which the frequency of the output varies under modulation. In these transmitters the carrier must be maintained very constant but under the influence of modulation the output frequency varies about the carrier as a mean value, the amount being determined by the type modulation and the audio-frequency signal. (L.R.Q.)

FREQUENCY DISTRIBUTION. A frequency distribution consists of the **variates** of a **serial distribution** (of more than 100 items) which have been grouped into mutually exclusive classes usually of equal width. From the frequency distribution any **statistics** may be calculated such as the **moments** or the **measures of central tendency.** The frequency distribution summarizes the data, making calculations and analysis much easier. The mathematical counterpart of the frequency distribution is the **probability function.** (L.A.A.)

FREQUENCY DIVIDER. Often in high-frequency measurements it is desirable to have available frequencies which are sub-multiples of some given frequency (i.e., the given frequency divided by a whole number). These sub-frequencies may be obtained by the use of a harmonic generator which, in this application, is called a frequency divider. **Oscillators** have a strong tendency to synchronize with an injected frequency which is not too different from their normal value. In certain types this tendency is so strong that a **harmonic** of the oscillator will synchronize with an injected frequency. It is this type which serves as a divider, the frequency to be divided is fed into the circuit of the dividing oscillator, causing the oscillator frequency to change so the proper harmonic is locked in with the injected signal. This, of course, means that the oscillator frequency is fixed at a sub-multiple value of the original frequency. The various harmonics of the synchronized oscillator then give a series of frequencies which might be said to be divisions of the original frequency. The **multi-vibrator** oscillator is widely used in this application. (L.R.Q)

FREQUENCY DOUBLER. The **oscillator** of a radio **transmitter** is often operated at a lower **frequency** than the output frequency of the transmitter. This has several advantages; among them may be mentioned less reflected effect on the oscillator and hence more stable operation, elimination of **neutralization,** stronger **crystals** than if they were ground for the higher output frequency, and in the case of frequency **modulation** a proportionate increase in the degree of modulation. A frequency doubler is usually a class C **amplifier** with its grid **tank** tuned to the frequency of the preceding stage (oscillator or amplifier) and its output tuned to twice this frequency. While the output power is reduced by this operation there is still sufficient output to drive another amplifier, or even in some cases to serve as the transmitter output. The energy which might be fed back from the output to the input of such an amplifier cannot affect the input or a preceding stage since every other cycle (because of this double frequency) will be 180° out of phase. This reduces the effect on the oscillator and also eliminates the need for neutralization. Doubling is used extensively in frequency modulated transmitters since the **frequency deviation** is doubled each time the frequency is doubled. In some transmitters of this type there may be a dozen or more doubler stages for this purpose. (L.R.Q.)

FREQUENCY DRIFT. This is the gradual change of carrier frequency which a poorly designed radio **transmitter** may undergo with time. It is usually caused by temperature effects in the **oscillator.** (L.R.Q.)

FREQUENCY, FUNDAMENTAL. In many a-c generating devices there are several frequencies produced,

all related in a definite manner. The lowest one of these frequencies is the fundamental frequency and the others are whole multiples of this. These multiples are the **harmonics.** In radio **transmitters** it is important to suppress all but the fundamental frequency of the output, since harmonics might cause interference with other signals. (L.R.Q.)

FREQUENCY HISTOGRAM. A frequency histogram is the graph of the **frequency distribution.** Rectangles are formed by using the **class interval** as the base and the frequency of the class as the height. Equal areas represent equal frequencies. (L.A.A.)

FREQUENCY METER. Most modern frequency meters for radio use are not **instruments** in the usual sense but are really several instruments and associated apparatus. The old absorption type wave-meter might be called a single instrument but it is not used except for rough measurements. It consists of a coil and **condenser** in series with some sort of indicator. The condenser may be varied to resonate the circuit (see **Resonance**) with the signal being measured. The indicator, which may be a simple lamp bulb or may be a vacuum-tube voltmeter, indicates resonance and the frequency is obtained from the condenser setting. Modern precision measurement of frequency utilizes a comparison process. The fundamental for this is the rotation of the earth. High-grade crystal **oscillators** are used to generate medium values of radio frequency, the output being compared with the rotation of the earth by synchronous clocks or by comparison with another oscillator which is so checked. Associated with this oscillator are various **multi-vibrator** oscillators serving as **frequency dividers** to give an extensive series of accurately known frequencies. The frequency to be measured is compared with the closest of these known frequencies by heterodyning and the resultant difference frequency (an **audio frequency**) determined in one of several ways. (See **Heterodyne.**) Very high frequencies are measured by exciting standing waves on an open or shorted transmission **line** and measuring the linear distance between nodes or anti-nodes of these waves. The frequency is then obtained by dividing the velocity (3×10^{10} cm./sec.) by the wavelengths in centimeters. For very accurate measurements several corrections must be applied to this method but it is sufficiently accurate for many purposes without the corrections. (See **Lecher Wires.**)

A common frequency-measuring **instrument** used for commercial power circuits is the vibrating reed instrument. This consists of many reeds, each tuned to a different frequency (commonly a half-cycle apart), which are set in vibration by the alternating flux of a **solenoid** connected across the circuit to be measured. Since the reeds are tuned, only those whose resonant frequency is very close to the circuit frequency will have appreciable amplitude, and the one closest to the circuit frequency will have the greatest amplitude. These reeds are mounted in a row or rows with the frequency scale on the adjacent face of the instrument. Another and more accurate frequency-measuring instrument for commercial circuits depends for its operation upon the effect on the moving element of the currents in two shunt circuits. One of these contains inductance and the other capacitance so the effect of a change in frequency is opposite in the two circuits. Since they are connected across the circuit to be measured their currents change with frequency and hence the moving element is deflected. (L.R.Q.)

FREQUENCY MODULATION. Modulation.

FREQUENCY MONITOR. Frequency monitor is used to give a continuous indication of any departure of a radio **transmitter's frequency** from its **assigned** value. This is usually done by comparing the station frequency with that of a crystal controlled **oscillator** in the monitor. The monitor frequency and the transmitter frequency are **heterodyned** and the **beat frequency** measured. Some monitors are adjusted to give zero beat frequency when the station is on the correct value, others give a difference frequency of some convenient value such as 1000 cycles. The beat frequency is fed to a circuit feeding an indicating instrument which shows zero for correct transmitter frequency and deflects to the right or left for high or low transmitter frequency. The scale is calibrated in cycles and the instrument indicates cycles off frequency. (L.R.Q.)

FREQUENCY POLYGON. A graph of the **frequency distribution** formed by graphing the class frequencies as **ordinates** and the class marks as **abscissas** and then joining these points by straight lines. It is usually drawn only in the case of a **discrete variable.** (L.A.A.)

FREQUENCY RESPONSE. By the frequency reponse of a circuit is meant the range of frequencies which it will pass with an allowable loss. The expression is quite commonly applied to audio **amplifiers, microphones** and **loud-speakers.** The frequency response of an audio amplifier usually drops off markedly at the low end and at the high end, the exact point depending upon the circuit and the values of various constants used in it. The response of a high-fidelity amplifier (one which would reproduce without appreciable frequency discrimination) should cover most of the audio band, i.e., from about 20 to 15,000 cycles. However this is much better than necessary except for the most refined work and a range of 30 to 10,000 cycles is usually considered high fidelity. Modern microphones have responses which will cover this latter range while some will extend over the entire audio band. Loud-speakers require the use of dual speakers or special resonant chambers, horns, etc., to cover this range. (L.R.Q.)

FREQUENCY STANDARD. This is the standard of frequency used in frequency measurement (see **Frequency Meter**) and is usually an extremely stable crystal controlled **oscillator.** The fundamental standard is the rotation of the earth and other standards are checked against this. Standards which may be checked directly (by means of synchronous clocks) are called primary standards while those which are checked against primary standards are called secondary standards. (L.R.Q.)

FREQUENCY TRANSLATION. Often in communication circuits it is desirable to move a frequency **channel** bodily to another part of the spectrum. This process is frequency translation and is performed by beating the frequencies to be moved with another fixed frequency. The sum or difference of the original frequencies and the beating frequency then gives the same channel at another point in the spectrum and by the proper choice of the beating frequency this new location can be fixed as desired. The process is used extensively in carrier telephony. It is also used in the doubling process (see **Frequency Doubler**) of some frequency **modulation** systems since the necessary doubling would raise the final frequency too high if it were not translated back to a lower value. Translation differs from doubling in that it does not bear a harmonic relationship with the original frequency and does not change the absolute width of the channel. (L.R.Q.)

FRESNEL COEFFICIENT OF DRAG. Ether.

FRESNEL MIRRORS. Young's Interference Experiment.

FRICTION BETWEEN WIND AND THE EARTH. Even though winds may blow with considerable velocity above the earth's surface, air cannot move rapidly in a very shallow surface layer where air molecules are caught in irregularities of the surface. This slowing of a wind at the earth's surface is the result of friction between moving air and the earth. The effect of friction extends to about 500 meters or 1500′. The first effect of reduced velocity is a reduction in Coriolis Force and therefore a pressure gradient which is not balanced. Because the pressure gradient is unbalanced, air flows across the isobars from high toward low pressure. Thus, unbalancing the pressure gradient causes air to converge toward low pressure and diverge from high pressure.

Over land the average deflection of air across the isobars at a height of 20–30′ is about 30°, and over water 20°. Reduction of wind velocity depends somewhat on the nature of the surface but, in general, above the friction level the wind velocity will be 1½ to 2 times that observed at the surface. (P.E.K.)

FRICTION BRAKE. Dynamometer.

FRICTION, FLUID. Fluid Friction, Pipe Friction, Drag.

FRICTION GEARING. A non-positive form of power transmission for rotating shafts. In the usual forms, friction gears may consist of cylindrical wheels, for transmitting power between parallel-axis shafts, and beveled wheels, for transmitting power between shafts whose axes will intersect if produced.

If friction wheels are assumed to operate without slip, the surface speed of both wheels must be equal. The velocity ratio of a pair of wheels is therefore inversely proportional to their diameters, or, if a 4″ wheel rotating at 300 rpm drives a 5″ wheel, the larger wheel will rotate at 240 rpm. In friction wheel drives, the driven wheel should be made of the harder material for if slip occurs, the softer driving wheel will wear uniformly about its periphery, and will not cut grooves into the surface of the driven wheel. Driving wheels may be made of leather, paper, or fiber; driven wheels are generally made of cast iron or aluminum.

The power H that may be transmitted by cylindrical friction wheels is given by

$$H = fFV/33{,}000$$

where f is the coefficient of friction between the wheel surfaces, F the contact pressure, and V the peripheral velocity, in ft. per min. Restrictions imposed by the ability of the friction wheel material to withstand crushing, and by the very heavy loads that the contact pressures impose on the shaft bearings, limit the use of friction gearing to light load transmission. (H.C.H.)

FRICTION, MECHANICAL. The chief causes of friction are the interlocking of the minute irregularities on the rubbing surfaces, adhesion between the surfaces, and the indentation of the softer by the harder body. Friction between solid bodies may be classified as sliding and rolling. The laws of sliding friction were investigated by Coulomb, who found that, approximately and within limits, (1) the friction between two surfaces is slightly greater just before motion begins than when the surfaces are in steady relative motion; (2) the friction is proportional to the force pressing the surfaces together; (3) it is independent of the area of contact, and (except at start) of the speed of relative motion. The constant ratio of the friction to the force pressing the surfaces together is called the coefficient of friction, some typical values of which are as follows:

Dry wood on dry wood	0.35
Leather on metal	0.55
Iron on stone	0.50
Wood on stone	0.40
Stone on stone or brick	0.65
Well-oiled metals	0.05

By means of such coefficients, it is possible to calculate what the friction will be between two bodies, as a wooden sill on a stone foundation, when the force pressing them together is given.

The angle at which a plane surface must be inclined for a solid block to slide steadily down it is the angle of friction; its tangent is the coefficient of friction between plane and block. Lubrication greatly reduces the coefficient by separating the solid surfaces. Rolling friction, due to the indentation of the surfaces in rolling contact, is much less than sliding friction, as illustrated by the use of ball-bearings. The **viscosity** of liquids and gases is sometimes called "internal friction." (L.D.W.)

FRICTIONAL ELECTRICITY. This familiar phenomenon is technically known as tribo-electrification. When two dissimilar substances are rubbed together, they become oppositely electrified; and if either is an insulator, it retains a charge. For example, if glass is rubbed with silk, the glass becomes positive and the silk negative. Careful experiments make it appear probable that this is a type of **contact potential difference,** and that the friction serves only to bring about surface contact over a larger area. Accurately ground and polished disks of steel and glass, when pressed firmly together to ensure close contact and then separated, show the same effect, the glass again being positive. Various experimenters have arranged lists of substances in such order that when any two are pressed or rubbed together and then separated, the one higher in the list becomes positive with respect to the other; but the data have often been conflicting. Coehn concluded from his experiments that the potential difference of the charges developed by two contacting **dielectrics** is proportional to the difference between their dielectric constants, the one having the greater constant being positive. (L.D.W.)

FRIEDEL-CRAFTS REACTION. Aluminum chloride anhydrous, introduced by Friedel and Crafts, is used as reagent, generally in **carbon disulfide** solution to avoid rise in temperature, for the preparation of (1) aryl-alkyl **hydrocarbons,** (2) di- and tri-phenylmethane and derivatives, and (3) aryl-alkyl and diaryl **ketones.**

1. Aryl-alkyl hydrocarbons. The reaction takes place between **benzene** or its homologues and the alkyl haloid, thus:

$$\underset{\text{Benzene}}{C_6H_5\cdot H} + \underset{\text{Methyl chloride}}{Cl\cdot CH_3} \rightarrow \underset{\text{Toluene}}{C_6H_5\cdot CH_3} + \underset{\substack{\text{Hydrogen chloride}\\ \text{gas evolved}}}{HCl}$$

$$\underset{\text{Benzene}}{C_6H_4\begin{matrix}\diagup H\\ \diagdown H\end{matrix}} + \underset{\substack{\text{Methyl}\\ \text{chloride}}}{\left.\begin{matrix}Cl\cdot CH_3\\ Cl\cdot CH_3\end{matrix}\right\}} \rightarrow \underset{\text{Xylene}}{C_6H_4(CH_3)_2} + HCl$$

2. Di- and tri-phenylmethane, derivatives. The reaction takes place between **benzene** and benzyl haloid or methylene haloid in the case of diphenylmethane, and between benzene and benzal haloid or chloroform in the case of triphenylmethane, thus:

$$\underset{\text{Benzyl chloride}}{C_6H_5CH_2Cl} + \underset{\text{Benzene}}{HC_6H_5} \rightarrow \underset{\text{Diphenylmethane}}{C_6H_5CH_2C_6H_5} + HCl$$

$$\underset{\substack{\text{Methylene}\\ \text{chloride}}}{H_2CCl_2} + \underset{\text{Benzene}}{\left.\begin{matrix}HC_6H_5\\ HC_6H_5\end{matrix}\right\}} \rightarrow \underset{\text{Diphenylmethane}}{C_6H_5CH_2C_6H_5} + \begin{matrix}HCl\\ HCl\end{matrix}$$

$$\underset{\text{Benzal chloride}}{C_6H_5CHCl_2} + \underset{\text{Benzene}}{\left.\begin{matrix}HC_6H_5\\ HC_6H_5\end{matrix}\right\}} \rightarrow \underset{\text{Triphenylmethane}}{C_6H_5CH\begin{matrix}\diagup C_6H_5\\ \diagdown C_6H_5\end{matrix}} + \begin{matrix}HCl\\ HCl\end{matrix}$$

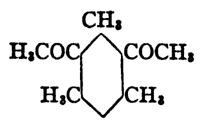
$$\underset{\text{Chloroform}}{HCCl_3} + \underset{\text{Benzene}}{\left.\begin{matrix}HC_6H_5\\ HC_6H_5\\ HC_6H_5\end{matrix}\right\}} \rightarrow \underset{\text{Triphenylmethane}}{C_6H_5CH\begin{matrix}\diagup C_6H_5\\ \diagdown C_6H_5\end{matrix}} + \begin{matrix}HCl\\ HCl\\ HCl\end{matrix}$$

3. Ketones. The reaction takes place between **benzene** and paraffin or benzenoid acyl haloid thus:

$$\underset{\text{Acetyl chloride}}{CH_3COCl} + \underset{\text{Benzene}}{HC_6H_5} \rightarrow \underset{\text{Acetophenone}}{C_6H_5COCH_3} + HCl$$

$$\underset{\text{Benzoyl chloride}}{C_6H_5COCl} + \underset{\text{Benzene}}{HC_6H_5} \rightarrow \underset{\text{Benzophenone}}{C_6H_5COC_6H_5} + HCl$$

The keto-group occupies the position para to alkyl already present. Two acyl groups have been placed in mesitylene to form diacetylmesitylene:



Summarizing: **Benzene** or its homologues plus paraffin-substituted haloid in the presence of **aluminum** chloride anhydrous react with the elimination of **hydrogen chloride.** In several cases an intermediate compound of the reactants with aluminum chloride has been identified. The reaction has been studied in detail by J. F. Norris and his co-workers.

Other reactions involving aluminum chloride anhydrous are:

a. **Xylene** plus **benzene** to yield **toluene,** and the reverse, namely, toluene to yield xylene plus benzene. Boiling temperature.

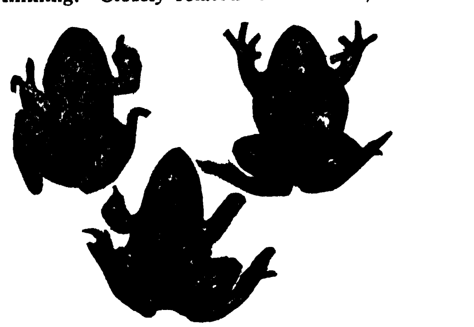
b. Benzene, toluene and homologues chlorinated by reaction with chlorine gas.

c. Benzene sulfinated by reaction with sulfur dioxide. Benzene sulfinic acid ($C_6H_5 \cdot SOOH$) formed. (R.K.S.)

FRIGATE BIRD. Aves, Pelecaniformes. *Fregata.* Marine birds (**Aves**) of slender build and powerful flight. They live chiefly on fish which they force other birds to give up to them. (A.W.L.)

FRITILLARY. Insecta, Lepidoptera. A **butterfly** of the genus *Argynnis.* Most species are red-brown with black markings and are spotted beneath with silver. Fritillary is also a genus of plants of the Lily Family, containing some 50 species growing in north temperate regions. They are mostly spring-blooming plants having bell-shaped flowers. The flowers are often spotted or mottled with dark purple and green spots. Most frequently grown are the snakes' head, *Fritillaria Meleagris* and the Crown Imperial, *F. imperialis.* Many of these plants have a strong fetid odor which prevents them from being too popular. (A.W.L., R.M.W.)

FROG. Amphibia, Anura. Tailless vertebrates with smooth moist skin and large hind legs, used for jumping and swimming. Closely related to the toads, which differ in their more terrestrial habits and warty skin. The forms are not sharply separated; arboreal species of the family Hylidae are called both tree frogs and tree toads. (See **Railway Track.**) (A.W.L.)



Three species of bullfrogs (*American Museum of Natural History.*)

FROG HOPPER. Insecta, Homoptera. Small jumping **insects** whose form faintly resembles that of the frogs. The immature insect sucks the sap of a plant and secretes about itself a protective frothy mass, hence they are also called spittle insects or spittle bugs. (A.W.L.)

FROG MOUTH. Aves, Caprimulgiformes. *Podargus.* Birds (**Aves**) of the Oriental and Australian regions with very short beaks and wide mouths. Related to the whip-poor-will and other goatsuckers. (A.W.L.)

FRONTAL APPENDAGE. An appendage of an extra pair between the second antennae of some **crustaceans.** (A.W.L.)

FRONTAL BONE. Bones of the vertebrate skull lying between and behind the eyes, usually paired but in most human skulls united to form the single large bone of the forehead. (A.W.L.)

FRONTAL ORGAN. An organ found on the front of the head of some **crustaceans.** Usually paired and probably sensory. (A.W.L.)

FRONTS, FRONTOGENESIS, AND FRONTOLYSIS. Surfaces of discontinuity between air masses are called frontal surfaces. The intersections of these frontal surfaces with the surface of the earth are called fronts. Frontal surfaces are also loosely spoken of as fronts. Actually the discontinuity usually extends through a varying zone of transition which is known as the frontal zone. By convention the exact frontal surface is taken as the boundary between the warm air and the frontal zone. Frontogenesis is the formation or intensification of a frontal surface. Frontolysis is the disintegration or weakening of a frontal surface Practically all frontal zones have clouds associated with them Some are accompanied by precipitation. A great percentage of temperate-zone precipitation and weather is directly the result of frontal activity.

The equilibrium slope of a front is given by the relation:

$$\tan \alpha = \frac{2\omega \sin \phi}{g} T_m \left[\frac{v_2 - v_1}{T_2 - T_1} \right],$$

where $\tan \alpha$ = Tangent of α, the angle of slope of the frontal surface to sea level.
ω = Angular velocity of the earth.
ϕ = Latitude angle.
T_m = Mean temperature of the air masses.
T_1, T_2 = Temperature of each air mass, respectively.
v_1, v_2 = Wind velocity parallel to the frontal surface in each air mass, respectively.

From this relation it is apparent that steep equilibrium frontal slopes result from high mean temperatures, high latitudes, large differences in the velocity components, and small differences in the temperatures between the two masses. The slope of a front is always such that cold air underlies warm.

There are two types of major frontal zones in the atmosphere resulting from the general circulation:

1. Between polar winds with an easterly component and sub-tropical winds with a westerly component surfaces of discontinuity develop known as polar fronts These are the world's principal fronts and cause much of the storminess of the temperate zone.

2. Between the northeast and southeast trade winds a surface of discontinuity is maintained known as the equatorial or inter-tropical front. Tropical cyclones develop on the equatorial front, particularly when it is displaced far north and south.

When polar fronts have pushed far south in mid-winter discontinuities begin to develop between the polar air and colder arctic air to the north. These fronts are called Arctic Fronts.

When the cold air on one side of a front is replacing the warm air horizontally the front is a cold front. A relatively narrow band of cloudiness and precipitation normally accompanies a cold front. At the approach, passage, and recession of a cold front in the northern hemisphere the following phenomena commonly occur in order:

1. Sky and weather. Increasing cloudiness of altocumulus, cumulus, or stratocumulus types; overcast with heavy showers; clearing to scattered cumuli.
2. Temperature and wind. Wind from southerly or westerly direction with temperature steady or rising slightly; wind shifting, sometimes with violent gusts and high velocity, from southwesterly to northwesterly and temperature starting to drop; wind fresh from new direction and temperature dropping steadily.
3. Pressure. Barometer falling prior to wind shift, then rising rapidly after shift and continuing to rise.

When the warm air on one side of a front is replacing the cold air horizontally and overriding the cold air, the front is a warm front. Over the average warm frontal surface a wide band of clouds and precipitation are present. Precipitation fog is also likely to form over a considerable area. At the approach, passage, and recession of a warm front, the following usually occur in order:

1. Sky and weather. Increasing cloudiness, first cirrus, then cirrostratus, altostratus, rain, or snow; stratus, nimbostratus, scud, sometimes fog a considerable period of time; clearing to scattered or broken stratocumulus and cumulus type clouds.
2. Temperature and wind. Wind from some easterly quadrant and temperature steady and relatively low; wind shift at front passage from easterly quadrant to southerly quadrant and considerable temperature rise; more or less steady southerly winds with much higher temperature.
3. Pressure. Barometer falling until wind shift, then steady or falling very slightly.

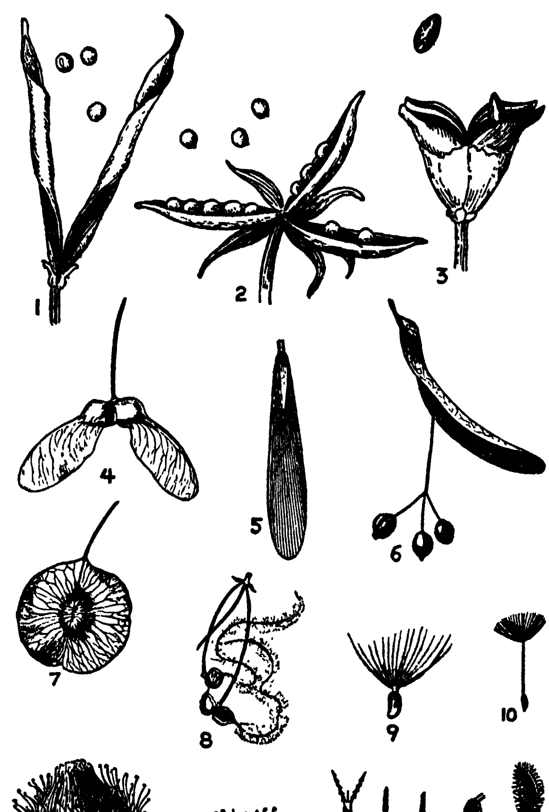
Cold-front slopes are greater than, and warm-front slopes are less than, the equilibrium slope. Stationary fronts have approximately the equilibrium slope. Cold fronts move with relatively steady velocity although subject to some acceleration. Warm frontal movement is commonly erratic, but generally slower than cold fronts.

Warm and cold fronts are common to the temperate zone, particularly in winter when large tropical and polar air masses alternately surge northward and southward. The equatorial front is relatively stationary but moves north and south seasonally. (P.E.K.)

FROST. Frost, like **snow**, is the result of the **sublimation** of water vapor in saturated air. If there is excessive radiation from solid objects, as on a clear night in late fall, the air coming in contact with them may be chilled below the sublimation point, and spicules of ice grow out from the cold surfaces. The process is entirely similar to the formation of metallic crystals artificially from vaporized metals on the interior of a glass tube communicating with the vaporizing furnace. In either case the size of the crystals is a matter of time and the supply of saturated vapor. Frost is often observed around cracks in a wooden sidewalk, because of the damp air escaping from the ground below. The objects upon which frost forms most readily are those of low specific heat and high thermal emissivity, such as blackened metals; hence the marked accumulation of frost on the heads of rusty nails. The apparently erratic occurrence of frost in adjacent localities is due partly to differences of level, the lower areas becoming colder; but also largely to differences in absorptivity and specific heat of the ground, which, in the absence of wind, greatly influences the temperature attained by the superincumbent air. It should be understood that vegetation is not damaged by frost itself, but by cold air; the appearance of frost merely indicates that the temperature has dropped below the freezing point. The formation of white frost on the indoor surface of window panes indicates low relative **humidity** of the indoor air; otherwise water would first condense in small drops and then freeze into clear ice. (L.D.W.)

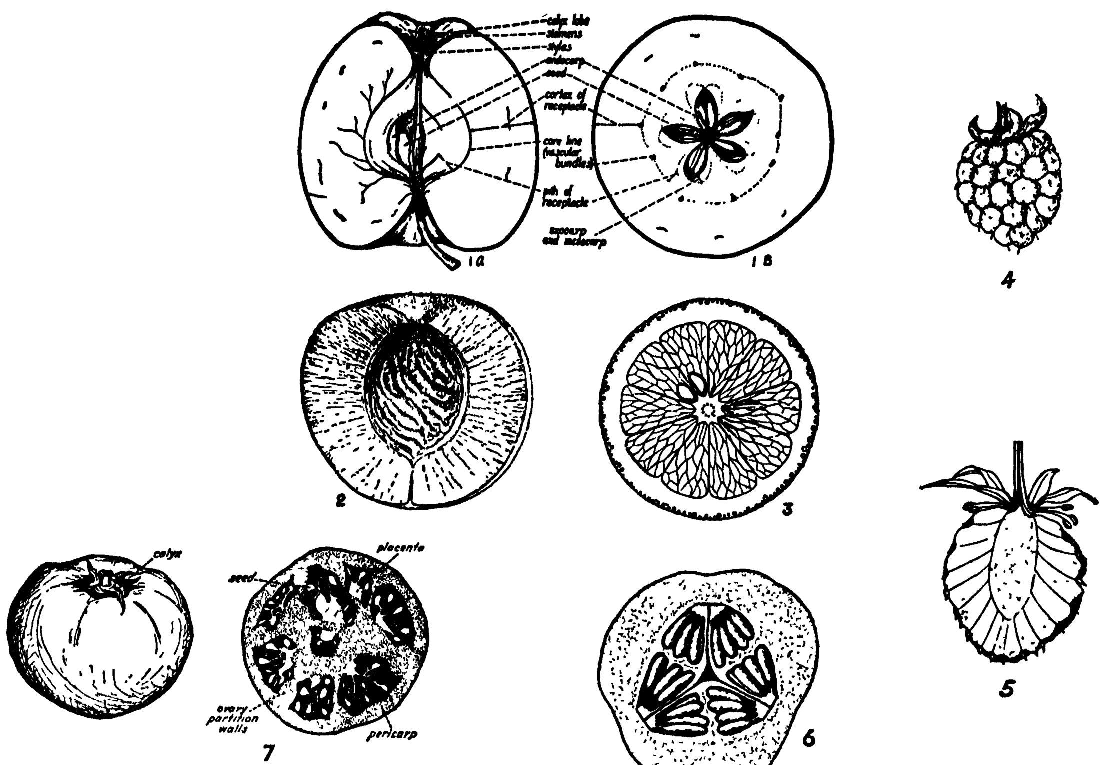
FRUCTOSE. Carbohydrates.

FRUIT. While this word is often used to describe any product of the soil, to the botanist a fruit is the ripened ovary of the **flower**. Often, however, it is necessary to amend this definition in order to include certain other tissues which are a part (often a very large part) of a fruit. In the strawberry, for instance, the red pulp is not the ovary, but a very much enlarged and modified stem tip, the receptacle of the flower. Another illustration is found in the "fruit" of the pineapple, a large part of which is stem and not ovary. Often, too, it is difficult to distinguish a fruit from a seed, and many fruits are invariably called seeds. Sunflower and strawberry "seeds" are really fruits, as are the "seeds" of grasses.



Dry fruits with devices for dispersal of their seeds. One to three, by sudden dehiscence. 1, wild bean; 2, violet; 3, witch hazel. Four to ten, by wind. 4, maple; 5, ash; 6, basswood; 7, elm; 8, *Clematis;* 9, thistle; 10, dandelion. Eleven to seventeen, by animals. 11, burdock; 12, cocklebur; 13, Spanish needle; 14, beggar's tick; 15, beggar's lice; 16, agrimony; 17, carrot.

There are many kinds of fruits. Usually they are separated into two classes, dry fruits and fleshy fruits. Dry fruits are again separated into dehiscent fruits, those which split open when ripe, and indehiscent fruits, which do not do so. Common dehiscent dry fruits are the legume, the follicle, and the capsule; dry indehiscent



Fleshy fruits. 1a and 1b, apple, illustrating pome (*after Robbins*); 2, peach, illustrating drupe (*after Decaisne*); 3, orange, illustrating berry (*after Decaisne*), 4, raspberry, illustrating aggregate fruit (*after Chamberlain*); 5, strawberry, illustrating aggregate fruit (*after Brown*); 6, cucumber, illustrating pepo (*after Chamberlain*); 7, mature fruit of tomato: left, surface view; right, cross section. (*Redrawn.*)

fruits are the achene, the caryopsis or grain, the samara and the nut. A legume is a fruit which when ripe splits along both edges; it develops from a single carpel. The pods of peas and beans are legumes. A follicle is similar to a legume, but splits along one side only. Milkweed pods are follicles. The fruits of the columbine and larkspur are also follicles. A capsule is a dehiscent fruit which develops from a compound ovary. The fruit of a lily or an iris is a capsule. The achene is a single-seeded indehiscent fruit which when mature has the seed free from the ovary wall except at the point of attachment. The fruits of the buttercup are achenes; also the fruits of the strawberry, which are the small hard bodies borne on the surface of the "berry." The achene of the composite family differs from the others in having the calyx tube coalesced with the ovary wall. A caryopsis or grain is very similar to an achene, but has the seed coat fused with the pericarp so that the seed cannot be removed from the ovary wall. The fruits of all cereal grasses are caryopses. The samara is an indehiscent fruit which has a wing. The fruits of the maple and elm tree are samaras. A nut is a very hard-shelled fruit, usually 1-seeded. Walnuts, acorns, and beechnuts are examples.

Fleshy fruits include the pome, the drupe, the berry, and many special types often called aggregate and multiple fruits. A pome is a fleshy fruit developed from an epigynous flower having a compound ovary. The flesh of the pome consists of an enlarged and ripened receptacle together with the outer layers of the pericarp. An apple is a pome. The tough paper-like part of the core is the endocarp. A drupe, or stone fruit, is developed entirely from the ovary. It is a 1-seeded fruit having a fleshy mesocarp and a hard endocarp. Peaches, cherries, prunes and olives are drupes. A berry is a fleshy fruit having all the pericarp fleshy, and containing one or more seeds. The fruit of the tomato, the grape, the banana and the cranberry are true berries. The "skin" of the banana represents the receptacle of the flower, and is thus stem tissue. In many plants the fruit is very similar to a berry, but is partly composed of receptacle tissue which forms a hard rind. These fruits, such as squashes, cucumbers and melons, are called pepos. If the outer wall of a berry is leathery, as in the orange, the fruit is known as a hesperidium.

Aggregate fruits are those which are formed from a single flower which had many simple pistils. In these fruits the receptacle forms a considerable part of the whole. Raspberries and blackberries are aggregate. In some fruits of this class the separate fruits break from the receptacle, as in the raspberry, while in others they remain firmly attached. The individual fruit in the raspberry is a tiny drupe, called a drupelet. A multiple fruit is formed from the ovaries of many flowers growing in a compact mass. Mulberries and pineapples are fruits of this type.

As the fruit ripens, the ovary wall or pericarp grows. Three layers of cell tissue are usually recognizable as the ovary matures. The outermost layer or exocarp, which is usually a thin layer, often an epidermis only one cell thick. The innermost layer is the endocarp. Between these is the mesocarp, in which the vascular tissues ordinarily occur. The relative thickness and appearance of these layers vary greatly in different fruits.

Often the structure of the fruit is directly correlated with the dissemination of the seeds. The principal agencies for fruit dispersal are wind, water, and animals. Many fruits are provided with wings, thin blade-like structures which enable the fruits to drift slowly downward and generally away from the parent plants. The fruits of the maple, the ash, and the ailanthus are pro-

vided with wings. The fruits of the dandelion and the thistle are familiar to all, though usually they are called "seeds." In them a group of slender hairs forms a parachute which enables the fruit to drift far away from its parent plant into new regions. Sometimes the fruit lacks any special structures which will aid in its dissemination, but is itself very easily blown about. The large pods of the honey locust are of this sort.

Many fruits, especially those of plants which grow along the shores of streams and other bodies of water, are carried about by the water. The large fruits of the coconut are often carried far from the parent plant.

Animals are an important means of dispersal of fruits and seeds. There are two ways in which the fruit may be thus carried. Very commonly hooks or barbs are formed on the surface of the fruit. Beggar's lice (the fruit of *Bidens*), and burdock, for example, are easily caught on the fur of a passing animal, and stay until some mechanical injury breaks off the hooks or barbed bristles and allows the fruit to fall. Some fruits, on the other hand, are covered with a sticky coating which causes them to adhere to the coats of passing animals, to be rubbed off later. Still other "seeds" have a soft, often tasty, outer wall, or edible mesocarp, and are eaten by animals. The hard inner wall of the fruit resists the action of the digestive juices, so that the seed passes uninjured through the digestive tract and is voided in a region often far distant from the place where it was eaten. Partial digestion of the endocarp may even aid the liberation of the seed for germination.

The explosive splitting of the walls of many fruits ejects the seeds violently, hurling them away from the parent plant. The seeds of the sand-box tree, *Hura crepitans*, are said to be hurled 50 yards and more, and those of the witch hazel 15–20′. (R.M.W.)

FRUIT FLY. Drosophila.

FRUIT SUGAR. Carbohydrates.

FUCHSINE. Dyes.

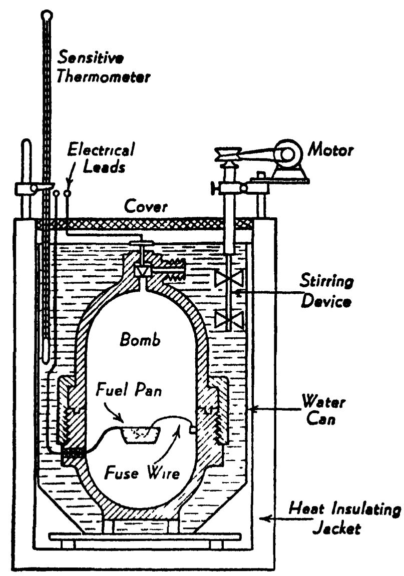
FUCOXANTHIN. Pigments in Plants; Amino-acids and Proteins.

FUEL CALORIMETER. The heating value of a fuel, in terms of heat units such as the B.T.U., may be obtained experimentally with the use of a fuel calorimeter. As fuels exist in solid, liquid, and gaseous states, fuel calorimeters would, of necessity, be required to be able to measure the heat of either solids, liquids, or gases. The conditions of measurement of a gas call for an instrument different in many essential respects from that which would be satisfactory for a solid or liquid fuel, principally because it is impractical to measure out a gas in definite isolated quantities, as is so easily done with liquids and solids. Hence a gas calorimeter is a continuous-flow instrument, whereas the liquid and solid fuel calorimeter is an intermittent type, wherein a known weight is burned. Nevertheless, the principle underlying the measurement of heat in all fuel calorimeters is the absorption of heat by water, creating a temperature rise. Measurements of the quantity of water and temperature rise are used directly to determine the heat units, since a unit of heat raises the temperature of a unit weight of water one degree. In the English system, the B.T.U. is indicated when 1 lb. of water at about 60° is raised in temperature 1° F.

The Junker's gas calorimeter is a chamber wherein a known metered flow of gas is burned in an efficient-type burner, with liberation of heat which is absorbed in water as the products of combustion flow through the tubular passages of the calorimeter. The water which absorbs the heat is likewise flowing steadily through the calorimeter, being separated from the gas by the walls of the tubes. The temperature of the water entering and leaving is measured by thermometers, while the rate of flow of water is measured by catching and weighing it. Thus the heat measured is a rate of heat liberation obtained by multiplying the rate of flow of water per min. by the temperature rise in degrees. This quantity, when corrected for radiation, moisture condensation, emergent stem, and other conditions, becomes the heating value of the gas per cu. ft.

The intermittent-type fuel calorimeter consists of a bomb which is charged with fuel and oxygen, and immersed in a bucket of water, which serves to absorb the heat when the charge inside the bomb is ignited. The temperature rise of the water is observed and the heat release determined by multiplying that rise by the known weight of water. That heat, divided by the weight of the measured sample of fuel, is the heating value—in the rough. Several corrections must be applied.

The figure illustrates a bomb calorimeter. A carefully weighed sample of the fuel to be tested is placed in the



Emerson bomb calorimeter.

pan within the steel bomb. A calibrated length of fuse wire is drooped into the pan, then the bomb is screwed tightly together. It is next connected to a tank of oxygen and charged with that gas to a pressure of several atmospheres, after which it is removed and immersed in the water of the calorimeter. When the water and calorimeter have arrived at room temperature, the electric leads are connected to a source of voltage through a switch, a stirring device is started, and the circuit is closed. The rush of current fuses the calibrated wire, raising it to a temperature sufficient to ignite the fuel in the presence of oxygen. The fuel then burns rapidly —almost explosively—and the heat it liberates is absorbed by the water. Temperature rise is measured by a sensitive thermometer. A large amount of water is used, so that the temperature rise will be very small. Corrections must be made for radiation, emergent thermometer stem, heating value of the fuse wire, water equivalent of the calorimeter, and energy input of the stirring device. (F.T.M.)

FUEL INJECTION. Fuel injection is taken to mean the direct injection of fuel into the **combustion chambers** of an internal combustion engine by means of an injection valve located in the wall of the chamber. For *injection carburetor* see **Carburetor Types.** Although the spark ignition engine (Otto) has been built for fuel injection, it is nearly universal practice to carburet the spark ignition engine and use fuel injection for the compression ignition (Diesel) engine.

The injection of fuel into a Diesel cylinder is a precise,

split-second operation. A minute quantity of fuel oil must be injected as a spray into air compressed to 500 lbs. per sq. in. and over. It must become well mixed with the air and burn almost instantaneously, yet at a definite rate so that pressure rise can be controlled. In a 100 hp. cylinder (not engine) of an engine operating at the moderate speed of 750 rpm the amount of each injection is approximately two *drops* of oil. The injection must be started, completed, and the burning finished all in approximately .01 sec. This description is illustrative of quantities for one of the larger Diesels, at full load. Part load operation and smaller power capacities would each decrease the volume of fuel oil injected. To meter such minute volumes accurately under the action of speed responsive *governors* and to inject it with proper timing and atomization into a region of "hard" air (i.e., highly compressed) requires the very best of machine work in construction of the injection pumps, which are the heart of the system, and of the injection valves. Maximum penetration of the fuel into the combustion chamber requires a dense spray of small diameter, but good mixing of fuel and air needs a fine, well-atomized spray which, unfortunately, has poor penetration. In some systems mixing is greatly assisted by special designs of the **combustion chamber.**

The pumps are small diameter plunger type pumps which usually open a by-pass for cut-off of fuel rather than curtail the plunger stroke. The arrangements of injection on multi-cylinder engines could be classified as follows:

Individual Pump System. In this, the most popular system, an injection pump is provided for each engine cylinder. A spring-loaded injection valve is provided in each cylinder and the pump discharge is connected to it by high pressure capillary-type tubing.

Common Rail System. A single pump maintains injection pressure in a common header from which branches lead to the injection valves. But now, the pumps not providing metering of fuel, the injection valve must be mechanically operated (cams and rocker arms, etc.) to provide the timing and metering function.

Distributor System. This may also be a single-pump system, but with the injection valve drive relieved of the need for metering the fuel. A single injection pump meters the fuel for all cylinders at low pressure. The metered fuel is delivered through a rotating distributor valve which shunts the metered fuel to the various injection valves. The mechanically operated valve plungers then raise the oil pressure sufficiently for spraying. Thus the valve action times and pressurizes the fuel but does not meter it.

Unit Injector System. In this system the functions of the pump and injection valve are combined in a single mechanical unit attached to the cylinder in the usual location of the injection valve. It must be mechanically operated and the method of actuation must include the timing, metering, and pressurizing function. Oil is furnished to the unit injectors from a common header supplied by a low-pressure pump.

In the early development of Diesels the best results were secured with air injection wherein small quantities of highly compressed air were employed at the injection valve to drive the fuel into the combustion chamber in a finely atomized state. The necessity of a high-pressure air compressor (usually three-stage with intercoolers) was a disadvantage, so when builders were able to overcome the problems of airless, or "solid," injection the air injection principle was gradually abandoned. (F.T.M.)

FUEL OIL. The petroleum oil obtained from wells in various parts of the earth is rarely suitable as a fuel oil in its crude form. Fuel oils are the crude oil after some of the lighter and heavier fractions have been removed. (See **Fuels; Hydrocarbons; Petroleum Products.**)

The principal production fields in the United States are in Pennsylvania, Ohio, Texas, and California. Petroleum is composed of a series of hydrocarbons in various proportions. A typical analysis of crude oil would be 84% carbon, 13% hydrogen, 1% sulfur, 1% nitrogen, 1% oxygen. Practically all of the hydrogen is "free" (that is, it is in a state of combination, as with carbon, in which most or all of its heat of combustion is available), and since it is in larger proportions by weight than in coal, fuel oil might be expected to have a considerably higher heating value. The principal uses of fuel oil at the present time are in **Diesel** engines, for firing in the furnaces of steam **boilers,** and for use in domestic oil-burning furnaces. The value of a fuel oil may be gauged by the following properties:

Calorific Value. This, of course, is important because it shows the amount of energy available. The calorific value of fuel oils is from 18,000 to 20,000 B.T.U. per lb.

Viscosity. Viscosity is one of the most important qualities of a fuel oil. It determines the fluidity of the oil and is a fair indication of how readily the oil will atomize. A very viscous oil may prove troublesome to handle without heating to a point where viscosity is more satisfactory. Viscosity is generally stated in terms of seconds, Saybolt Universal, at some specified temperature, usually 100° F.

Ignition Quality. This characteristic measures the ability of fuel oil to ignite spontaneously in an engine cylinder. Good ignition quality is represented by high **cetane number.** Ignition quality is an index to possible detonation, ease of starting, and smoky exhaust.

Carbon Residue. The standard test for this characteristic is the **Conradson Test** which gives an indication of the amount of carbon that may be deposited as a scale in an engine combustion chamber. Although low-carbon residue is a desirable quality and will yield better engine operation, the lower cost of less completely distilled fuels makes them more economical in use.

Solid Impurities; Ash and Asphalt Content. The effect of these is to cause deposits in the combustion chamber and around the piston rings, necessitating increased maintenance. Ash is the most detrimental quality in fuel oil.

Water Content. Few oils are free from water, but a good oil will not contain more than 1% of water. Besides forming sludge, the water content decreases the calorific value of a fuel.

Sulfur and Acid. These components will cause corrosion of cylinders and valves under certain conditions.

Gravity. The Baumé scale is one of specific gravity.

$$\text{Degrees Baumé} = \frac{140}{\text{specific gravity}} - 130$$

(For liquids lighter than water)

The specific gravity is referred to water as 1. Suitable fuel oils range from 15–43° Baumé. The Baumé reading is useful in determining whether the oil is burdened with an undue amount of heavy residue which is difficult to burn successfully.

Flash and Boiling Points. These indicate the degree to which a fuel can be vaporized; also the inflammability and hence the fire risk of storage and handling. (F.T.M.)

FUELS. Fuels are those materials which when burned with air or **oxygen,** furnish heat energy. The rate at which a given fuel is burned determines the temperature at the point of burning. Since heat flows from bodies at a higher to those at a lower temperature in proportion to the temperature difference between them, the temperature of combustion is important when the rate of heat flow is a consideration.

The materials used as fuels fall into two grand divisions, (1) fuels—gases, liquids, solids—for ordinary combustion, (2) fuels for non-ordinary or **internal combustion engines,** motor and stationary. These are either

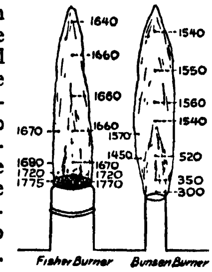
gases or volatilizable liquids, usually **petroleum** or coal tar products, capable of rapid reaction (explosion) when mixed with air or oxygen and ignited. This *ignition* is usually accomplished by an electric spark, but high and rapid compression (that is, **adiabatic**, without heat loss, energy of compression being accounted for by temperature rise) is sufficient in certain cases, for example, in the **Diesel engine.**

The heat-evolving chemical elements in domestic and industrial fuels are **carbon** and **hydrogen.** Carbon as such is utilized in coke and charcoal, and hydrogen as such in hydrogen gas for high-temperature combustion, and in fuel gas mixtures, such as coal gas, water gas, producer gas and blast furnace gas. Carbon and hydrogen compounds are present (1) in the hydrocarbons of natural gas, petroleum and most of its products, and coal and most of its products, and (2) in the carbohydrates and lignins of wood and peat.

The naturally occurring fuel materials are (1) natural **gas,** (2) **petroleum,** (3) **coal** (a variety of forms), (4) **wood,** (5) **peat,** and (6) **lignite.** Artificial fuels are prepared (1) by the **destructive distillation** of coal (soft or bituminous coal) resulting in coal gas, coal tar and coke, (2) by the destructive distillation of wood resulting in charcoal, (3) by the fractional and destructive (cracking) distillation of petroleum, resulting in **gasoline,** and lower and higher boiling point distillates in "still" gases and in fuel oil residue, (4) by fuel gas reactions, resulting in water gas from coke and steam, in **producer gas** from coal or coke and air, oil-water gas from petroleum and steam. Other fuels are (1) blast furnace and other gases containing combustible material often with sensible heat at temperatures sufficiently high to be useful as sources of heat, (2) **alcohol,** (3) **ben zene,** (4) **ethylene,** (5) **acetylene.**

Naturally Occurring Fuels: 1. *Natural gas.* Contains up to 95% of **methane.** Used as a fuel, and by incomplete combustion as a source of carbon pigment or lamp black. 2. *Petroleum.* (See **Hydrocarbons.**) Distilled to obtain gasoline, kerosene, lubricating oils, low boiling distillates, high boiling distillates, fuel oil, gas carbon. 3. *Coal. a.* Bituminous, of 12,000 to 15,000 B.T.U. per lb., of variable ash content as to amount of ash and as to the clinkering or fusing temperature of the ash. Used as fuel, or treated by destructive distillation to obtain coal gas, coal tar, coke, thence **benzene,** water gas, producer gas. Current and future developments are powdered coal, low-temperature distillation, hydrogenation. *b.* Sub-bituminous, of less than 12,000 B.T.U. per lb. Used as fuel. Important future reserve. *c.* Lignite and peat. Used as fuel. Important future reserve. *d.* Anthracite, of 14,000 B.T.U. per lb., more or less. Used as fuel, of diminishing importance. 4. *Wood.* Used as fuel, value as such markedly affected by the water content as heat from combustion is required to vaporize the water. Freshly cut wood usually contains 60% or more water, calculated on the weight of dry wood. Heating value of air dried woods approximately 21 (plus or minus 10%) million B.T.U. per cord, equivalent to approximately 0.8 short ton of coal of 13,000 B.T.U. per lb. Treated by destructive distillation to obtain methyl alcohol, woodtar, charcoal, and by burning to obtain carbon dioxide. 5. *Carboniferous shale.* Important future fuel reserve by treatment by destructive distillation to obtain hydrocarbon distillates. (See **Destructive Distillation.**)

Artificially Prepared Fuels. 6. *Coal gas.* Used as fuel. Treated to obtain **benzene, toluene, ethylene.** Oil-water gas is practically the same mixture as coal gas. Approximate composition: **methane** 30%, **hydrogen** 50%, **carbon monoxide** 6%, **ethylene** 2.5%. Fuel value: 550 (more or less) B.T.U. per cu. ft. 7. *Coal tar.* Treated by fractional distillation to obtain benzene, toluene (and other coal tar crudes). 8. *Coke.* Used as fuel and metallurgical reducing agent. Treated to obtain water gas, producer gas, carbon monoxide. 9. *Charcoal.* Used as fuel and metallurgical reducing agent. 10. *Gasoline.* Used as motor fuel (and as solvent and diluent). (See **Hydrocarbons,** paraffin.) 11. *Low boiling naphtha.* Used as special motor fuel (and as solvent and diluent). 12. *High boiling kerosene and stove oil.* Used as fuel and illuminant. 13. *Fuel oil.* Distillation residue used as fuel in ordinary or internal combustion. Heating value approximately 19,000 B.T.U. per lb., which is more than 150,000 B.T.U. per gal. 14. *Water gas.* Made by reaction of coke and steam at furnace temperatures. Used as fuel, and source of **hydrogen** and **carbon monoxide.** Approximate composition: hydrogen 45%, carbon monoxide 45%. Approximate fuel value: 350 B.T.U. per cu. ft. 15. *Producer gas.* Made by reaction of coke or coal and air at furnace temperatures. Used as internal combustion fuel. Approximate composition: 25% carbon monoxide. Approximate fuel value: 100 B.T.U. per cu. ft. 16. *Blast furnace gas.* Used as fuel and for the sensible heat content. Approximate composition: 25% carbon monoxide. Approximate fuel value: 100 B.T.U. per cu. ft. 17. *Alcohol.* Future fuel possibility, either straight or blended with other liquid fuels. When 1.1% of water is present in a mixture containing 80% gasoline plus 20% alcohol separation into two layers takes place. (See **Ethyl Alcohol.**) 18. *Benzene.* Minor use as fuel. Future fuel possibility, either straight or blended with other liquid fuels. Excellent antiknock fuel for internal combustion, and miscible with gasoline. (See **Benzene.**) 19. *Ethylene.* Excellent fuel for local high temperatures, used in special burner with oxygen. (See **Ethylene.**) 20. *Acetylene.* Excellent fuel for local high temperatures, used in special burner with oxygen. (See **Acetylene.**) 21. *Hydrogen.* Excellent fuel for local high temperatures, used in special burner with oxygen. An important component of coal gas, water gas. (See **Hydrogen.**)



Temperatures in degrees Centigrade of gas flames.

HEATING VALUE OF VARIOUS INDIVIDUAL FUEL SUBSTANCES

Individual Fuel Gases	Higher Heating Value (Water Condensed as formed in Combustion) In B.T.U per cu. ft. at 60° F. and 30 in. (Hg) pressure	In kilogram-calories per gram-molecular weight
Methane	995	211
Ethane	1730	368
Propane	2465	526
Butane	3200	680
Ethylene	1615	332
Acetylene	1455	312
Hydrogen	319	68.4
Carbon monoxide	317	67.1

Individual Fuel Liquids	Higher Heating Value Kilogram-calories per gram	Kilogram-calories per gram-moleculai weight
Normal-pentane	11.6	883
Normal-hexane	11.5	990
Normal-heptane	11.5	1150
Normal-octane	11.4	1303
Methyl alcohol	5.34	171
Ethyl alcohol	7.13	328
Normal-propyl alcohol	8.00	481
Benzene	10.0	782
Toluene	10.2	934

INDIVIDUAL FUEL SOLIDS	HIGHER HEATING VALUE Kilogram-calories per gram
Carbon, amorphous, to carbon dioxide	8.08 (97.0 Kg-Cal per gram molecular weight carbon dioxide)
Carbon, amorphous, to carbon monoxide	2.49 (29.9 Kg-Cal. per gram molecular weight carbon monoxide)
Cellulose............	4.21

The examination of fuels is conducted with various purposes in mind. An "ultimate" analysis is designed to give the percentage of each element present, by burning **carbon** element to **carbon dioxide, hydrogen** element to water, **sulfur** element to **sulfur dioxide** or to **sulfate, nitrogen** element to nitrogen gas, **phosphorus** element to phosphate, inorganic residue as ash. The ash may be analyzed. The heating value of a fuel is determined by burning a definite weight or volume of a gas in a calorimeter. A "proximate" analysis is designed to give the percentage of water, of volatilizable material under given conditions of temperature and time, and of non-volatile combustible residue. A determination of the softening temperature of the ash may be made. A "rational" analysis is designed to give the percentage of each compound in the fuel. This is accomplished in the case of gases by measurements of volume before and after absorption in definite reagents or other treatment applied in a definite order. For complex mixtures of liquids and solids this type of analysis is difficult, and at present impossible in the case of some, for example coal, although some progress has been made. Special tests are sometimes demanded, as in studying the coking conditions of coal, and the explosive and power characteristics of internal combustion fuels. The velocity of explosion of certain gas mixtures has been measured by Dixon.

GAS MIXTURE TAKEN	PRODUCTS OBTAINED	OBSERVED VELOCITY OF EXPLOSION METERS PER SEC.
$2H_2 + 2O_2$	$2H_2O + O_2$	2328
$8H_2 + O_2$	$2H_2O + 6H_2$	3532
$CH_4 + O_2$	$H_2O + COH_2$	2528
$C_2H_4 + 2O_2$	$2H_2O + 2CO$	2581
$C_2H_2 + O_2$	$2CO + H_2$	2961

Industries using fuels for the production of high temperatures are ceramics, Portland cement, glass, pig iron, steel, copper, zinc, lead, nickel, tin, destructive distillation of coal. The economies introduced in the use of coal since World War I are of such degree as to appreciably affect the demand for this fuel. In 1919, the fuel consumption per thousand gross ton miles by Class I steam railroads using coal-fired locomotives was 170 lbs., whereas in 1941 it was only 111 lbs ; and for public utility central station electric power plants using coal the fuel consumption in 1919 was 3.2 lbs. per kw-hr. and in 1941 the average was 1.3 lbs. (R.K.S.)

FULGURITE. A vertical, sometimes branching tube of fused quartzitic sand formed from the intense heat developed when the sand is struck by lightning. (R.M.F.)

FULLER'S EARTH. This is a fine-grained earthy substance similar to **clay** both in appearance and composition, but it lacks plasticity and is usually high in **magnesia.** It has the property of decolorizing oils and removing grease from raw wool. (E.S.C.S.)

FULMAR. Aves, Procellariiformes. Large marine birds (**Aves**) resembling the gulls. **Petrels.** (A.W.L.)

FULMINATES. Cyanic Acid.

FUMAROLE. Derived from the Latin *fumus,* smoke, the term fumarole is applied to openings in the earth's crust, often in the neighborhood of volcanoes, which emit steam and gases such as **carbon dioxide, hydrochloric acid,** and **hydrogen sulfide.** A special name, solfatara, from the Italian *solfo,* sulfur, is given to fumaroles that emit sulfurous exhalations. Perhaps the greatest area of fumarole activity is the famous Valley of Ten Thousand Smokes, adjacent to Katmai volcano, Alaska. (R.M.F.)

FUNCTIONAL. In medicine, functional means pertaining to or affecting the function of the body, and not its structure. A functional disorder is one in which there are no obvious anatomical changes. The term is used most commonly to denote disorders of psychogenic origin.

In mathematics, a functional is a **function** whose argument or independent variable is a curve or surface (or a corresponding function). It may also be described as a function of a function. (R.S.M., L.L.S.)

FUNCTIONS. If two **variables** are so related that to each value of one variable in a given range there correspond one or more values of the other variable, the second variable is called a function of the first variable.

The first variable is often called the independent variable and the function is sometimes called the dependent variable.

If one variable is so related to several variables that to each set of values of the last-mentioned variables there correspond one or more values of the first variable, the first variable is called a function of the other variables.

If a variable y is an **explicit function** of another variable x, the function is often denoted in general by such symbols as $f(x)$, $F(x)$, $\phi(x)$, etc., and we write $y = f(x)$, etc. The symbol $f(a)$ then denotes the value of the function $f(x)$ for the value $x = a$.

A function of two variables, as x and y, may be represented in general by such symbols as $f(x, y)$, $F(x, y)$, etc.; and similarly for functions of more than two variables.

A function which takes one value only, corresponding to any given value of the independent variable, is called a single-valued function.

A multiple-valued function is a function which takes more than one value corresponding to any given value of the independent variable.

Functions may be classified in many ways, as: **explicit functions** and **implicit functions; continuous functions** and discontinuous functions; **algebraic functions** and **transcendental functions,** and each of these classes into many sub-classes; **periodic functions,** etc. (L.L.S.)

FUNCTIONS OF A COMPLEX VARIABLE. The theory of functions of a complex variable may be described briefly as the **differential** and **integral calculus** of complex variables. (L.L.S.)

FUNCTIONS OF REAL VARIABLES. The theory of functions of real variables may be described briefly as a critical study of the fundamental concepts and processes of the **differential** and **integral calculus.** (L.L.S.)

FUNGI. Mushrooms, Toadstools, Smuts, Rusts, Molds and Mildews. The fungi are a group of plants of such diverse habit that they cannot easily be collectively described. Among the more than seventy thousand species described at the present time are many microscopic unicellular forms, as well as plants of elaborate structure and considerable size. Fungi grow in almost every habitat where organic substance exists and the external conditions are suitable. Many species are found in water, either fresh or salt. Others are adapted to life on land, or in the ground. Even in the Arctic regions

fungi appear in numbers during the short summer. In the tropics fungi are particularly abundant, the hot, often humid climate greatly favoring their existence.

In one particular, however, fungi are all alike: they have no **chlorophyll**, and so are unable to synthesize food from simple substances. Instead, the fungi obtain their nourishment from various organic substances. Many attack living organisms, both plant and animal. These are parasites, often of great importance to man because of the damage caused to crops. Other fungi attack dead organisms, breaking down the organic compounds present into simpler forms and obtaining thereby their own sustenance—these are saprophytes.

Excepting the entire absence of chlorophyll, the structure of fungi resembles that of the **algae**, the other main division of the **Thallophytes**. The vegetative body of a fungus, except for the unicellular forms, is always composed of slender branching threads, or hyphae, making up what is known as the mycelium. Mycelia in many cases are colorless, but may contain pigments of every color, including green. Each hypha is ordinarily composed of a row of cells, each containing one (or more) minute nuclei; in many species cross walls are rarely formed, the hypha being coenocytic. Even the largest, most complex fungi are composed entirely of tangled masses of hyphae, which may be loosely aggregated or so densely packed as to form a hard body suggestive of woody structure, as for example in the Bracket Fungi.

In their reproductive processes fungi again remind one of the algae. Both asexual and sexual reproduction occur in the life histories of these plants, which also often show very distinctly an alternation of vegetative growth and reproductive activity. As may be expected, in so diversified a group of plants a considerable variety of reproductive processes occurs.

Among the lower forms, many of which occur in water, asexual reproduction is accomplished by means of zoöspores. The zoöspores are formed in sporangia from which they escape at maturity. After a period of motility, each zoöspore settles down, loses its cilia and at once gives rise to a new plant. In the non-aquatic fungi asexual reproduction ordinarily occurs by means of non-motile spores, called conidia, which have a rigid cell-wall. These conidia, often produced in immense numbers, are carried about by air-currents, sometimes to great distances, and on reaching a favorable habitat, germinate to form a new plant. The methods of sexual reproduction found in fungi are extremely varied, and can best be considered under the different groups. Sexual reproduction usually occurs in a distinct body, the sporophore, which forms in many fungi a very conspicuous part of the life cycle of a fungus. This is frequently the only part recognized by the ordinary observer. In each kind of fungus the sporophore assumes a very definite and distinct form. In the cup fungi the sporophore is frequently a saucer- or cup-shaped structure. Other types are found in the familiar mushroom; in the puff-balls; and in the Bird's-Nest Fungus, the sporophore here having many small somewhat spherical objects contained in an open cup-like body. In all of these, spores are formed, often in unbelievable numbers; a common puff-ball contains millions of them. The spores are borne about in the air currents, and germinate when brought to a favorable environment. It is obvious that many spores must fail to reach such a favorable spot, else the world would be overrun with fungi.

Fungi are separated into three classes, the **Phycomycetes**, in which the mycelium is non-septate and coenocytic; the **Ascomycetes**, characterized by having spores borne in special sacs or asci; and the **Basidiomycetes**, distinguished by the basidium, a spore-bearing cell which bears externally four spores, in some cases more or less. In addition to these three classes there is another group known as **Imperfects**, or **Fungi Imperfecti**, which contains those forms of plants in which the sexual or perfect stage is not known, and which therefore cannot be assigned to one of three mentioned classes. Some botanists would include in the Fungi two other groups of plants: the **Bacteria** and **Slime-molds**.

Fungi are of prime importance to man, first because of the immense loss caused by saprophytic forms. These attack food-stuffs, causing complete spoilage; attack fabrics which they mildew and so ruin; and attack and cause the destruction of timbers. In spite of all this, it must be stated that such forms are very necessary; for the very processes of destruction they perform are necessary preparations for new growth. Were all rotting prevented the accumulation of dead matter would soon become so great as to hinder and stop life. Only the lower plants, notably fungi and bacteria, are able to break down complex matter to forms in which it is again available for higher organisms.

Somewhat less important to man are the parasitic fungi. They may attack his crops and cause immense damage, as in the case of Wheat **rust**, but usually remedies or preventatives are found to keep such pests under control, and to prevent them from becoming serious problems. Not many species attack man himself. Some, like the fungus which causes Athlete's Foot, are annoying. Since few are fatal, the fungi of this type have received little attention until recently.

Many edible forms of fungi are enjoyed by man. Of these many are species which grow wild. To distinguish those species which are edible from those which are harmful is an ever present problem. To style the edible species mushrooms and reject the others as toadstools does not solve the problem, since it first becomes necessary to define the terms "toadstool" and "mushroom." And there is no obvious distinction. The only safe rule to follow is that of total abstinence from any doubtful species until one is absolutely certain that it is safe. It is thus only natural that man has turned to the cultivation of fungi. Of all the edible species known, only a few have been successfully cultivated. Of these only one is commercially important, *Agaricus (Psalliota) campestris.* The spawn of this fungus is planted on properly heated beds (usually underground) of well-rotted horse manure piled in long ridges. Spawn consists of bricks or flakes of prepared manure permeated with fungus mycelium. After planting, this mycelium rapidly grows through the beds, which are then covered with fine earth and left undisturbed for a time. After a month or so mushrooms begin to appear on the surface of the beds. They grow with astonishing rapidity, and must be cut soon after appearing, or they will reach maturity and disintegrate. The food value of mushrooms is probably much overrated, as most of them are actually over 90% water, with some nitrogenous matter and no fat. But they are much fancied for their palatability and fine flavor. It is interesting to note that one group of tropical ants feeds largely on fungus plants, which they grow in their nests in an advanced state of cultivation.

The poisonous nature of many fungi has received wide publicity, and probably accounts for the popular aversion to this group of plants. The toxic substances present in the fungus are products of its **metabolism**, not substances absorbed from without. It may be that these substances are some sort of waste products accumulating in the cells. Some people have suggested that they are a means of protection against animals which might otherwise eat the plant. However, many animals eat with impunity fungi which are violently toxic to man, so it seems difficult to maintain this explanation. The toxic substances present in fungi are various. Closely related species may contain quite different poisons; a single species may have more than one poison. The effect of the poison on the human body varies. One group of poisons is taken into the body some hours before its effects become evident. Then

abdominal cramps and nausea develop; vomiting occurs; thirst arises and diarrhea. These symptoms continue for hours, usually (but not always) ending in death. This is the type of poisoning caused by *Amanita phalloides*. *Amanita muscaria* is less violent in its action. The poison of this fungus acts on the nerve centers, causing lack of coordination, illusions and delirium, as well as gastric disturbances. *Amanita muscaria* is only very rarely fatal. This fungus is used by native tribes of northeastern Siberia as a stimulant. In addition to the *Amanitas,* many other fungi are of poisonous nature. It also seems that the effect varies among different people. What one finds edible may be definitely toxic to another. This renders even more difficult the problem of satisfactorily determining harmful species. (R.M.W.)

FUNGUS GNAT. Insecta, Diptera. Small two-winged **flies** whose larvae live on fungi and decaying vegetation. Family Mycetophilidae. (A.W.L.)

FUNICULAR POLYGONS AND CATENARIES. If a closed loop of cord or rope is pulled at several points by forces in various directions, it forms a figure, plane or otherwise, known as a funicular polygon. The external forces acting on the loop at the vertices are, for **equilibrium**, subject to the same conditions as a set of non-concurrent **forces** acting on a rigid body; while the three forces concurrent at each vertex, including the tensions in the loop itself, may be represented by an equilibrium triangle, and the several triangles fitted together to form the equilibrium polygon for the external forces (Fig. 1). Fig. 2 gives the corresponding an-

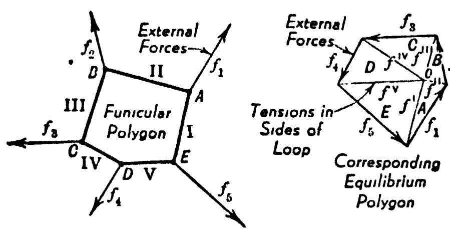


Fig. 1. Closed funicular polygon with diagram of forces.

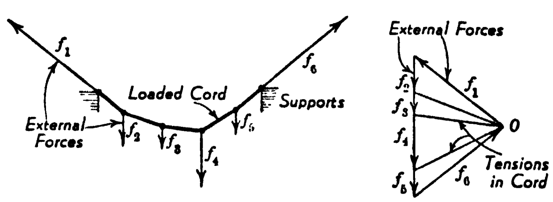

Fig. 2. Suspended cable with unequal loads.

alysis for an open cord supported at the ends and loaded by weights hung vertically from it. In Fig. 3 the weights are equal, have equal horizontal spacing, and

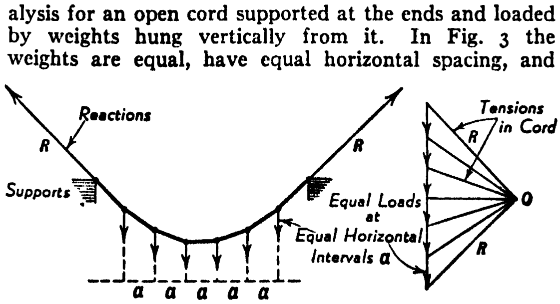

Fig. 3. Suspended cable with equal loads, as in a suspension bridge.

are hung close together. The form of the cord in this case approximates a parabola. This condition practically obtains with the cables of a suspension bridge. The point O in each figure is located by drawing from the extremities of any side of the external-face polygon lines parallel to the sides adjacent to the corresponding vertex of the funicular polygon.

If a suspended cord is loaded uniformly along its length (not horizontally), as by its own weight, it assumes the form of a **catenary.** The equation of this curve may be written

$$y = \frac{a}{2}\left(e^{\frac{x}{a}} + e^{\frac{-x}{a}}\right) = a \cosh\frac{x}{a}.$$

(The hyperbolic cosine form is convenient for numerical computations.) a represents the Y-intercept of the curve. It is an interesting property of a catenary cable that if at any point it is hung over a pulley, and enough cable cut off to reach down to the X-axis (Fig. 4), the weight

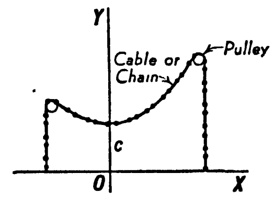

Fig. 4. Tension of chain in catenary balances weight of chain hanging down to X-axis.

of this portion will just sustain the tension on the other side of the pulley. The funicular-polygon theory is sometimes useful in solving equilibrium problems involving nonconcurrent forces. (See **Statics.**) (L.D.W.)

FUNICULUS. A cord. Specifically: 1. A structure attaching the alimentary tract of the **bryozoans** to the body wall. 2. A slender segmented part of the antenna of some **insects,** just before its terminal segment. 3. A bundle of nerve fibers in its sheath. 4. Tracts of nerve fibers in the central nervous system of **vertebrates.** 5. The stalk which attaches the seed to the **placenta** of the fruit. (A.W.L.)

FUNNEL. 1. The tube leading out of the mantle cavity of the **squids** and related mollusks **(Mollusca).** The siphon. 2. The oral depression of **lampreys.** (A.W.L.)

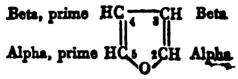
FUR. The fine soft hair of many mammals. Also the pelt, the skin of the animal bearing the fur, especially when made up to be worn as a scarf.

Fur shares with feathers the highest position as a protection against cold. It owes this property to the insulating value of the layer of air held among the fine hairs that compose it. In many animals the vestiture consists of a thick woolly under layer interspersed with longer and heavier hairs which form a smooth surface.

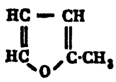
The best furs are those of animals which live in the colder latitudes and especially the semi-aquatic species. The sea otter of the northern Pacific produces the most valuable fur, and mink and muskrat are examples of moderately valuable and low-priced furs. Fox and skunk are among the commercially important terrestrial species. All of these animals should be taken in the winter to furnish durable pelts. Summer fur is not only thinner but separates readily from the skin.

The preparation of fur for the market now involves so many processes, such as plucking, shearing, and dyeing, that only an expert can judge skins dependably. Trade names add to the confusion and give false dignity to many furs of very modest worth. Many of the seals on the market, for example, are clipped and dyed muskrat or rabbit fur. (A.W.L.)

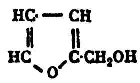
FURANE AND RELATED COMPOUNDS. Furane (C_4H_4O) contains a ring of 1 oxygen and 4 carbons, with 1 hydrogen attached to each carbon:



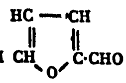
Furane is a colorless liquid, boiling point 32° C., insoluble in water, soluble in alcohol or ether. Furane vapor produces a green coloration on pine wood moistened with **hydrochloric acid.** Furane may be made from mucic acid ($COOH(CHOH)_4COOH$) by dry distillation into pyromucic acid ($C_4H_3O \cdot COOH$) and then heating the latter under pressure at 270° C. Furane derivatives are known, namely, methyl, primary **alcohol, aldehyde, carboxylic acid,** in which the group attachment is at carbon number 2:



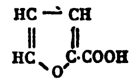
Sylvane Alpha-methyl furane, boiling point 65° C.



Furfuryl alcohol Alpha-furyl carbinol boiling point 170° C. (750 mm.)



"Furfural," Alpha furfuraldehyde boiling point 160° C. (740 mm.)

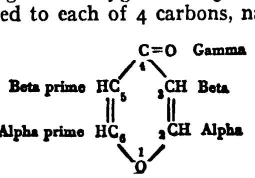


Pyromucic acid, furoic acid, furane-alpha-carboxylic acid, Melting point 133° C. boiling point 230° C.

(See **Furfuraldehyde.**)

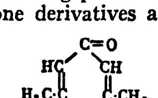
Coumarone is benzo-furane (C_8H_6O or $C_6H_4CH{:}CH{\cdot}O$ or , colorless liquid, boiling point 173° C., and diphenylene oxide is dibenzo-furane ($C_{12}H_8O$ or $C_6H_4 \cdot C_6H_4 \cdot O$ or  white solid, melting point 81° C., boiling point 288° C.

Gamma-pyrone ($C_5H_4O{:}O(4)$) is a gamma-ketone (4) containing a ring of 1 oxygen and 5 carbons with 1 hydrogen attached to each of 4 carbons, namely, 2,3,5,6,

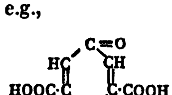


Gamma-pyrone is a colorless liquid, melting point 32° C., boiling point 218° C.

Pyrone derivatives are known, e.g.,



Alpha, Alpha prime dimethyl-gamma-pyrone



Chelidonic Acid Gamma-pyrone-alpha, alpha-prime-dicarboxylic acid

Chromone is benzo-pyrone ($C_9H_6O_2$) or  white solid, melting point 59° C, and chromane is  colorless liquid, boiling point 214° C. (750 mm.)

Flavone is phenyl chromone:  white solid melting point 97° C.

Xanthone is dibenzo-pyrone ($C_{13}H_8O_2$ or C_6H_4  C_6H_4 or  white solid, melting point 174° C., boiling point 351° C., and xanthene is  white solid, melting point 100° C., boiling point 315° C. From chromone and xanthone a number of yellow dyes are made, which dyes also occur in nature. Such dyes are chrysin, fisetin, buteolin, morin, quercetin, rhamnetin.

Where oxygen of furane is occupied by sulfur, thiophene is the compound, and of coumarone, benzothiophene; and where oxygen of furane is occupied by nitrogen (group —NH), pyrrole, and of coumarone, indole. (R.K.S.)

FURCA. A pair of divergent projections at the caudal end of the body of some **crustaceans.** (A.W.L.)

FURCULA. The jumping appendage of a spring tail. **Collembola.** (A.W.L.)

FURFURALDEHYDE. Furfuraldehyde ($C_4H_3O \cdot CHO(2)$) is a colorless, odorous liquid, boiling point 162° C. When pentoses, e.g., arabinose, xylose (see **Carbohydrates**), are heated with dilute **hydrochloric acid,** furfuraldehyde is formed, recognizable by deep red coloration with phloroglucinol, or by the formation, with **phenylhydrazine** of furfuraldehyde phenylhydrazone ($C_4H_3O \cdot CH{:}NNHC_6H_5$), solid, melting point 97° C. Furfuraldehyde is formed by the treatment of corn-cobs, bran, or wood, with **sulfuric acid,** and can be used in many instances where **formaldehyde** is utilized, as a disinfectant, insecticide, and for a raw material for the manufacture of synthetic plastics and resins; also as a solvent for organic substances, and to prepare furfuryl alcohol ($C_4H_3O \cdot CH_2OH(2)$) and furoic acid (pyromucic acid, $C_4H_3O \cdot COOH(2)$) for furoates. (R.K.S.)

FURNACE. A furnace may be said to be a chamber for **combustion.** In addition, it provides support and enclosure for the firing equipment and partial enclosure for equipment sometimes inbuilt into the furnace, as, for example, the boiler of a steam generating unit. It surrounds the region where the combustion reaction takes place, confining and isolating it so that it remains a controlled force.

The furnace is a relatively important component of any steam power plant. The success of a boiler installation is so dependent upon the furnace which serves it that the importance of correct furnace design cannot be over-emphasized. The furnace converts the latent chemical energy of raw fuel into a dynamic form (heat). There are many interesting, puzzling, and difficult problems in the field of furnace design. Even when this field is limited to boiler furnaces one finds a great variety of service conditions calling for an equally great variety of applications. Many of the questions which arise have already been answered by scientific testing and by experience, but some points are still met by the liberal allowance method.

The design of a boiler furnace cannot be carried out independently of other equipment, for its success will require coordination of several important factors, among which may be mentioned:

1. Type of combustion equipment.
2. Character of the fuel used, especially its ash content.
3. Draft equipment employed.
4. Air supply and degree of preheating.
5. Boiler, and its baffling arrangement.

In former years, especially when steaming equipment had been standardized for a time, and before pulverized coal firing had inspired the remarkable progress in combustion that it has, furnaces were customarily designed on the basis of certain volumetric requirements per **boiler horsepower.** This method related furnace volume to heating surface, and naturally became inadequate when this heating surface, under the stress of improved methods of firing coal, was required to transfer several times the heat it formerly did.

Recently, furnace volumes have been based on *heat liberation,* meaning the number of B.T.U. produced per hour per cubic foot of furnace volume. To fix upon furnace dimensions by this method requires only the division of the hourly heat liberation by some acceptable volumetric rate. This rate is not deductible from theory,

but fortunately numerous data are available as to rates actually employed in successful designs.

There is much to be said for both theory and experience in boiler furnace design. The heat release method is hardly theoretical, but represents an enlightened approach compared with the older methods. When leaving long established practices behind, and in pioneering installations, experience may usefully be employed to season theory and computation.

Furnaces classified according to their wall construction are (1) solid refractory, (2) air-cooled refractory, (3) water-cooled, either totally or partially.

Recent progress in this field, stimulated by the introduction of high capacity firing, has greatly increased our knowledge of the part played by radiant energy in the furnace. Radiant energy reverberates back and forth in the furnace until gases are at their final flame temperature because flame is opaque to radiation. If cold black surfaces such as water walls are met in the process of reverberation large amounts of high-level energy will be absorbed, less will be reverberated to the flame whose temperature will, in consequence, be less. It is well established that a heat transfer of approximately 75,000 B.T.U. per sq. ft. per hour is realized. Not only water walls, but water screens and those portions of the boiler heating surface that "see" the furnace, absorb radiant energy. In many of these the fuels are burned in contact with the material being processed while in other, i e., crucible and muffle furnaces, the material is separated from the combustion being placed in a separate chamber or crucible. For descriptions of some types of metallurgical furnaces see **Bessemer Process, Blast Furnace, Cupola, Electric Furnace, Open Hearth Process, Refractory.** (F.T.M.)

FURUNCLE. A boil. A localized infection of the skin and subcutaneous tissues occurring singly or multiply. The usual infecting agent is the *Staphylococcus.* (R.S.M.)

FUSAIN (FUSSIN). A term proposed by Stevenson in 1911 for what had previously been called "mineral charcoal" or "mother of coal" The highly oxidized **cellulose** and blackened woody fibers which form an important constituent of most true coals. (R.M.F.)

FUSE. A fuse is a common protective or circuit breaking device for low-voltage **electric circuits.** It is an over-current protector, and since the current must first heat the metal, there is a time delay in fuse "blowing" that is inversely proportional to the current. This characteristics is called "inverse time element." The ordinary fuse consists of a calibrated length of conductor whose resistance is so chosen that when a certain current flow through it is exceeded, it fails to lose by radiation enough of the resistance heat to keep its temperature below melting. The fuse is enclosed in a protective case which forms the contact points to connect it into its circuit. Sometimes the case contains a powder which helps to extinguish the arc which follows the blowing of the fuse element in high-capacity fuses. Sometimes, also, the case is provided with a glass cover, which allows one to discover at any time the integrity of the fuse. Fuses for 110-volt house circuits usually take the form of a plug which can be screwed into a socket. They are standardized at 5, 10, 15, 20, 25, and 30 amperes. Cartridge type fuses have been standardized with ferrule contacts up to 60 amperes, and knife contacts above that. There are a number of other types, such as expulsion fuses, thermal overload fuses, etc., that are not discussed here. The National Electric Code specifies that if fuses are used for motor protection, their capacity must not exceed 125% of the name-plate rating of the motor. The detonating device on a shell is a fuse as is the powder-filled cord used in setting off any charge. (F.T.M.)

FUSED SALT BATHS. Quenching, Heat Treating, Steel.

FUSEL OIL. Alcohols.

FUSELAGE, AIRPLANE. The fuselage is the body of an airplane. It must perform many functions such as providing adequate space for the power plant, fuel tanks, crew, passengers, and cargo, and necessary equipment and controls, and it must also transmit lifting, thrusting, balancing and landing loads from one part of the airplane to another. Probably because of the great number of possible combinations of the variables, fuselage designs are found in utmost variety of forms and constructions; nevertheless, all fuselages have much in common in that they will have similar outlines and arrangement of the primary components. Fuselages are smooth externally, with a minimum of projections into the airstream; they are slender, and generally have a fineness ratio (see **Parasite Drag**) greater than that which would yield the minimum drag. The attachments to the wing, and the space for crew and passengers, are usually in the forward 50–60% of the fuselage, and the long, tapering tail section carries the empennage for control and balance. As the fuselage accounts for one of the larger components of weight of the airplane, every effort is made to keep it as light as possible; however, there can be no compromise with necessary strength, as the fuselage supports parts vital to safety in flight, and any partial structural failure would invite catastrophe. In cross-section, fuselage outlines of various forms, i.e., oval, rectangular, elliptical, round, usually have one feature in common; that is, the depth exceeds the breadth. This is in deference to the primary nature of the fuselage acting as a cantilever beam supported by the wings and loaded at the tail with a balancing load.

Fuselages for single-engined airplanes are designed to bear an engine, mounted at the forward end. As the engine is a heavy concentrated load which in operation produces torque and thrust, this part of the fuselage structure must be made quite rigid, and therefore heavy. Extremely high loadings may occur on the forward end of this type of fuselage during hard landings on account of the sudden arresting of the downward momentum of the engine mass upon contact of the wheels with the ground. It is required that the engine compartment forward of the fuselage be separated from the fuselage by a firewall which is a thin partition of asbestos board or sheet metal. Multi-engined airplanes have the engines carried on the wing structure, in which case the forward end of the fuselage is neatly faired around in front of the control cabin.

In flight, the fuselage and contents consists of dead structural load, controls, instruments, crew, passengers, cargo, and miscellaneous other equipment, all of which is supported by reactions received from the wing structure, is pulled forward by thrust received through the engine mount, and is held in any desired attitude by balance and control forces set up on the tail surfaces. The operation of the rudder and ailerons will, in addition, impose side loads and twisting upon the fuselage, as will also the operation of a bi-motored airplane with one engine out of service. Unskillful landings are capable of producing extremely heavy impact loads at the juncture of the undercarriage with the fuselage, and will produce large bending moments in other parts of the fuselage. So, one sees that the fuselage must be able to resist torsion and bending in almost every direction. It must accommodate the mounting of a great deal of small equipment internally, and there are many cut-outs to be reckoned with, such as windows and doors, all of which complicate the problem of design.

Fuselages may be variously classified. On account of the many variations representing ideas of individual designers, the classification given here is not claimed to be all-inclusive.

1. Fuselages classified according to seating arrangement.

a. Degree of exposure of the personnel.
   (1) Completely enclosed, as in cabin airplanes.
   (2) Open cockpits. Head and shoulders usually protrude above the fuselage, being partially protected from the airstream by forward windshields.
   (3) A modification of (b), wherein a glass or transparent plastic hatch, bubble, blister, or other form of cover, is used to enclose and protect the occupants. Whereas entry to a cabin airplane is obtained through side doors, this type is entered by having the cockpit cover hinged or sliding.

b. Relative position of the seats.
   (1) Tandem seating arrangement.
   (2) Side by side.
   (3) Both (a) and (b) apply mainly to the small two-place airplane. Three-, four-, and five-place airplanes usually incorporate a combination of side by side and tandem seating.
   (4) Large multi-engined planes designed to carry many passengers will typically exhibit a control compartment in the nose, where the pilot and co-pilot are seated side by side. Back of these there may be space provided for other crew members, such as flight engineer, navigator, etc., or there may be a galley and steward's compartment. Next aft would be the main passenger cabin, with seating arrangements similar to that of railway trains or motor buses, except that, in the smaller transports, there may be only a single row of seats on each side of a center aisle.

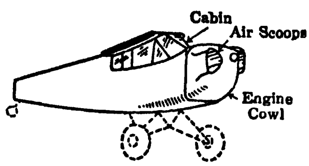


Fig. 1. Light plane type fuselage (trussed structural skeleton).

2. Structural types.

a. Trussed frame structures.
   (1) Round steel tubes welded into a triangularly framed truss structure.
   (2) Round or square aluminum alloy tubes, riveted or bolted into a truss structure, sometimes including diagonal wires as tension members.
   (3) Trusses constructed by riveting members composed of drawn steel or aluminum alloy strip.

b. Monocoque structures.
   (1) Full monocoque construction. This is rarely employed. Full monocoque construction relies on the strength of the skin or shell to carry all the load. Its only reinforcement consists of transverse bulkheads used to define the shape. Unless the curvature is considerable, the necessary skin thickness is uneconomically heavy; hence it is seldom used except for small diameter monocoque tubes such as booms.
   (2) Semi-monocoque construction. This is adaptable to large diameters, using thin skin, because in the semi-monocoque fuselage the skin is reinforced by an interior framework. This is the construction employed on most metal fuselages of the stressed skin type.

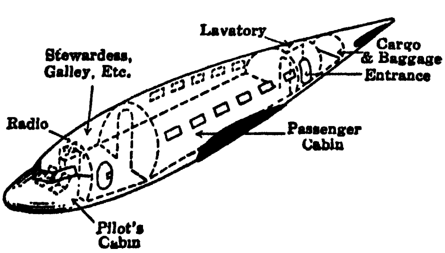

Fig. 2. Transport type fuselage (semi-monocoque construction).

c. Reinforced skin. A stressed skin covering is applied to a framework consisting of longitudinal stringers, transverse rings, and diagonals.

d. "Geodetic" construction. A form of construction employing a diagonal basket-like weave of many closely spaced stringers to which is attached the surface covering.

3. Materials of construction.

a. Wood. Although early airplanes were frequently constructed with wooden fuselages, these tended to become obsolete, but, latterly, the development of high-grade waterproof and flexible plywood, and the improvement in adhesives available, have made it possible to construct excellent stressed skin wood fuselages.

b. Metal. The most common metal for welded steel tubular fuselage is seamless chrome-molybdenum steel. For stressed skin either 17 ST or 24 ST aluminum alloy is employed. Where the surface is not to be finished with paint, the alloy sheets are covered with a thin surface of a pure aluminum serving as a protecting coating. This sheeting is known by the trade name "Alclad." Thin sheets of stainless steel also have been employed in fuselage construction.

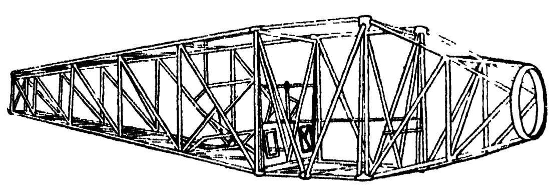

Fig. 3. Welded tubular steel fuselage.

4. Unconventional fuselage types.

a. Flying wing. Here there is no separate fuselage, room to accommodate the normal fuselage functions being provided in a thickened midsection of the wing.

b. Twin tail. When the empennage is carried by two booms extending back from the wing structure, the fuselage can be made in a better aerodynamic proportion, say with a length about three or four times its width.

c. Canard. In the canard design the empennage is placed ahead of the fuselage.

The truss type of fuselage is built in the form of a rectangular beam with its flanges composed of tubes located at the four corners of its rectangular cross-section. These are the four longerons. These longerons, together with vertical web members, compose two side trusses which are usually built as an irregular Warren truss with welded joints. The trusses in the plane of the upper chord and lower chords give transverse rigidity, and diagonals are introduced to oppose torsion. The necessity of these diagonals, which pass through the interior of the fuselage, is a disadvantage of this construction, since they interfere with the full usage of the in-

terior space for accommodation of cargo and personnel. Concentrated loads are comparatively easy to introduce into the trussed structure by applying them to the joints of the truss. Where redundancies occur, as around door openings, the corners must be heavily braced with reinforcement. As the best shape for the truss will not ordinarily be a good aerodynamic shape, a light-weight false work of formers is attached to the primary structure so that the covering, when attached, will be of a neatly faired, aerodynamic shape. The covering is ordinarily light-weight fabric attached securely to the formers, and made taut and smooth by repeated applications of airplane "dope."

Large fuselages of semi-monocoque construction represent the maximum strength with minimum weight type of construction, which is so desirable in aviation. Being a shell it has good torsional stiffness. This construction also leaves the interior comparatively clear of structural bracing. In spite of the recent importance of this construction it is not new, for as early as 1911 Handley-Page had built a wooden monocoque fuselage, and during the decade from 1910-1920, there were several airplanes built with metal monocoque fuselages. The cross-sectional shape is derived from bulkheads or rings, and the longitudinal profile is determined by stringers. The thin metal skin is riveted to these members (if plywood, the skin is glued and nailed to the members, which are then wooden) and combines with the underlying framework to carry the loads previously mentioned. The bulkheads are at much larger intervals than the stringers. In order to employ thin gauge skin without the stiffeners being at unreasonably close intervals, it is sometimes corrugated. Unlike the trussed fuselage, in the stressed skin design it is not easy to apply concentrated loads to the fuselage. At the points of reception of localized loads, the structure must be specially stiffened. While this might be done by employing especially stiff bulkheads, specially built-up assemblies which are designed to distribute loads around the shell are located at the points receiving concentrated load. In a semi-monocoque construction the stringers take the bending moment, and the shear flow is conducted by the skin The calculations for design are detailed and complex, but after the structure is built it is possible to check the design by applying strain gauges to the structure while it is being artificially loaded. Thus the adequacy of the design can be established before committing the structure to the air. Probably no one thing causes more difficulty in the arrangement of a monocoque structure to carry a load than the numerous cut-outs which have to be accommodated, such as window and door openings, cargo hatches, etc. However, in spite of the complications, successful and light-weight fuselages are constructed with stressed skin, and the advantages appear sufficiently important that it might be predicted that only the light airplanes of the future will employ trussed fuselages. (F.T.M.)

FUSION. A change from the solid to the liquid phase of matter. In crystalline bodies, and, we are beginning to understand, also in many other solids not exhibiting well-defined **crystal structure,** the atoms are held in positions of stable equilibrium by intermolecular forces. They of course move with thermal agitation, but their movements are oscillatory and do not carry them outside a limited range of distance from their equilibrium positions. Stable equilibrium may, however, become unstable when the system is disturbed beyond a certain limit. Thus if a solid body is sufficiently heated, the molecules break loose from their stable configuration and wander about or diffuse among each other. When this condition has become general, the body exhibits the characteristics of a liquid, and we say it has undergone fusion. In some cases, such as ice, the change is quite abrupt, the substance having a well-defined **melting point;** in others, like glass or pitch, it is gradual. The difference is probably due to the more uniform potential energy of the atoms in the former case, so that they all "break loose" at the same stage of thermal agitation; while in the latter case some atoms require more energy to dislodge them than others. In any case the process requires a supply of energy which is recognized as the **heat of fusion.** With most substances, fusion is accompanied by an increase in volume; but with some, like ice, the volume becomes definitely less. (L.D.W.)

G

GABBRO. Gabbro is a deep-seated and often very coarse-grained **igneous** rock composed of **plagioclase feldspar,** usually **labradorite** or **bytownite** and **monoclinic pyroxene** with occasionally as accessories **olivine** (when it is then called olivine gabbro), **biotite, magnetite, ilmenite** and **hornblende.** Norite is a variety of gabbro carrying **orthorhombic** pyroxene, usually **hypersthene** instead of the monoclinic sort. Troctolite is essentially olivine and plagioclase. **Quartz** gabbros are known and have probably been derived from **magmas** somewhat oversaturated with **silica.** On the other hand **essexites** represent gabbros whose parent magma doubtless had an insufficiency of silica resulting in the formation of **nephelite.** Gabbros are frequently rich in sulfides that may be of commercial value, a notable occurrence of which is at Sudbury, Canada. Here a norite carrying **chalcopyrite** and nickeliferous **pyrrhotite** forms the most important deposits of nickel known. Gold, silver and platinum are also recovered from this ore. (E.S.C.S.)

GADOLINIUM. Symbol: Gd. Atomic number: 64. Atomic weight: 157.3. (**Isotopes:** page 290.) Type of compound: Gd_2O_3. Color of salts: Colorless. Discovered by Marignac in 1886. A member of the **cerium** sub-group of the rare earth metals. (R.K.S.)

GADWALL. Aves, Anseriformes. A North American **duck,** *Anas strepera.* (A.W.L.)

GAHNITE—ZINC-SPINEL. The mineral gahnite is **isometric** with an **octahedral** habit but may appear as **dodecahedrons** or modified cubes. Chemically it is **zinc aluminate** corresponding to the formula $ZnAl_2O_4$. There is a tendency for cleavage parallel to the octahedron, fracture varies from conchoidal to uneven; brittle; hardness 7.5–8; specific gravity 4–4.6; luster vitreous; color ranges from dark green through various shades of greenish- or bluish-black, yellowish-black or grayish, subtransparent to almost opaque. Gahnite is found in association with other zinc minerals at several European localities, notably in Bavaria and Sweden. In the United States it is found at Franklin and Sterling Hill, New Jersey; at Rowe, Massachusetts and in Maryland, North Carolina, Georgia and Colorado. Gahnite was named in honor of the Swedish chemist, J. G. Gahn. (E.S.C.S.)

GAIN. Amplifier; Directional Antenna.

GALACTIC COORDINATES. As the modern theories regarding the structure of the sidereal **universe** became more and more firmly established, it became necessary to have a system of **spherical coordinates** for the representation of points relative to the plane of the **milky way,** or the **galactic plane.**

The galactic coordinate system is a system of spherical coordinates having as its fundamental plane the plane of the milky way (or galaxy). The adopted position of the pole of this plane is $12^h\ 40^m$ **right ascension** and 28° north **declination.** The plane of the milky way cuts the plane of the celestial **equator** at an angle of 62°. Galactic latitude is measured perpendicular to the plane of the galaxy along great circles drawn through the galactic poles and hence perpendicular to the galactic plane. Galactic longitude is measured in the plane of the galaxy from the point where this plane cuts the plane of the equator in right ascension $18^h\ 40^m$ to the point where the great circle perpendicular to the galactic plane through the object intersects the galactic plane. (W.K.G.)

GALACTIC SYSTEM. Milky Way.

GALAGO. Mammalia, Primates. The African **lemurs.** The several species are long-tailed animals whose nearest relatives are the mouse lemurs of Madagascar. (A.W.L.)

GALAXY. Milky Way.

GALEA. Maxilla.

GALENA. The mineral galena, **lead** sulfide, PbS, crystallizes in the **isometric** system, usually in cubes or cube-octahedron combinations, less frequently in **octahedrons.** It is often found in cleavable masses, but may be granular or fibrous. The highly perfect cubic cleavage is an important characteristic of this mineral; it may, however, sometimes show an octahedral parting. Its hardness is 2.5; specific gravity, 7.3–7.6; luster, metallic; color, lead gray; streak, grayish-black; opaque. Galena is the most important ore of lead and in addition often carries values of **silver;** it is then known as argentiferous galena. It occasionally is actually mined as a silver ore. Sometimes galena contains small amounts of **zinc, cadmium, antimony, bismuth,** and **copper** as sulfides. Galena is a very common and widely spread mineral, it occurs in veins and beds in various rocks, both crystalline and sedimentary. Some of these deposits are doubtless replacements, others seem to show a close connection with intrusive igneous rocks. Of the many foreign localities might be mentioned the classic one at Freiberg, Saxony, and the silver mines of the Harz Mountains. This mineral has been found in the lavas of Vesuvius, in Italy, and fine specimens come from Cornwall and Cumberland, England. Australia, South America, Chile, and Peru produce galena. In the United States, Missouri, Illinois, Iowa, and Wisconsin contain large and important galena deposits. In Colorado and Idaho it has been mined for its silver content. Galena is usually associated with **sphalerite, smithsonite,** and at **Phoenixville,** Pennsylvania, with beautiful **pyromorphite** crystals. The name is derived from the Latin *galena,* a term which was applied both to the lead ore and slag from refining. (E.S.C.S.)

GALL. Gall is the secretion of the **liver** of vertebrates, also called bile. (A.W.L.)

GALL BLADDER. A pear-shaped organ (see figure) situated on the underside of the **liver** on the right side just below the lower ribs. It serves as a reservoir for the **bile** and by means of the cystic duct it communicates with the common duct through which the bile secreted by the liver passes to the **duodenum.** The gall bladder is about 3″ in length and 1–1¼″ in diameter. It holds about 1½ ounces of bile. When fatty substances are eaten, the normal gall bladder empties the stored, concentrated bile into the common duct. Upon passing into the duodenum the bile aids in the **digestion** of the **fat.**

The gall bladder under certain conditions is subject to acute and chronic infections (**cholecystitis**) and to stone formation (**cholelithiasis**). Under these conditions its function is lost and, since it is a source of infection to the body, and often the cause of continued distressing symptoms, it should be removed (cholecystec-

tomy). No ill effects follow the removal of the gall bladder, as the common duct serves as a reservoir in its place. (R.S.M.)

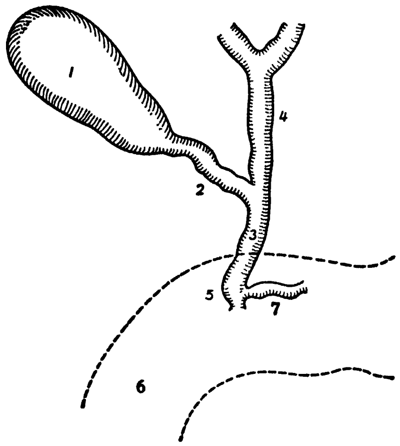

Diagram of biliary tract. 1. gall bladder; 2. cystic duct; 3. common bile duct; 4. hepatic duct; 5. opening of bile duct into the duodenum, 6. duodenum; 7. duct from the pancreas. (*Whipple, A. O., Surgery of the Biliary Tract, Nelson's Loose-Leaf Surgery,* Volume 5.)

GALL GNAT. Insecta, Diptera. Small 2-winged **flies** of many species constituting the family Cecidomyiidae. Most are plant feeders as larvae and produce **galls** on the plants that they attack. Others are predacious or scavengers. (A.W.L.)
